Dedications

To my father,
my mother,
my wife,
my sons:
Abd El-Rahman,
Muhammed,
and Amr

To president Muhammad Mursi

”ليعلم أبناءنا أن أباءهم وأجدادهم
كانوا رجالاً ، لا يقبلون الضيم
ولا ينزلون أبداً على رأي الفسدة
ولا يعطون الدنيا أبداً من وطنهم
أو شرعيتهم أو دينهم“

د. محمد مرسي رئيس الجمهورية - ٢ يوليو ٢٠١٣

ד"ר מוחמד מרסי - 2 יולי 2013

ד"ר מוחמד מרסי - 2 יולי 2013

كلما نظرت في وجهه رأيت أبي، غفر الله لنا جميعاً

Take the first step, and your mind will
mobilize all its forces to your aid.

But

The first essential is that you begin

Once the battle is startled, all that is within
and without you will come to your assistance

مقدمة

الحمد لله حمداً كثيراً على أن وفقني لإخراج هذا العمل، وأتمنى أن يستفيد منه كل طالب علم، وأن يجعله خالصاً لوجه تعالى، مع رجائي لكل من يستفيد منه بالدعاء لي ولأسرتي ولسائر المسلمين بظاهر الغيب.

لقد استفدت كثيراً من تجارب الكثير والكثير من الأصدقاء، وبدون عونهم ما خرج هذا العمل بهذه الصورة، لذا لا بد أن أوجه لهم كل الشكر والفضل في هذا العمل.

حاولت في هذا الملف أن أستفيد من خبرات الكثير من الزملاء، وكل مجهودي كان في الجمع والترتيب والتنسيق، أتمنى أن يكون في ميزان حسناتي يوم القيامة.

Reference ranges

Reference ranges vary according to individual labs.

All values are for adults unless otherwise stated

Full blood count

Haemoglobin Men: 13.5-18 g/dl

Women: 11.5-16 g/dl

Mean cell volume 82-100 fl

Platelets 150-400 x 10⁹/l

White blood cells 4-11 x 10⁹/l

Urea and electrolytes

Sodium 135-145 mmol/l

Potassium 3.5 - 5.0 mmol/l

Urea 2.0-7 mmol/l

Creatinine 55-120 umol/l

Bicarbonate 22-28 mmol/l

Liver function tests

Bilirubin 3-17 umol/l

Alanine transferase (ALT) 3-40 iu/l

Aspartate transaminase (AST) 3-30 iu/l

Alkaline phosphatase (ALP) 30-100 umol/l

Gamma glutamyl transferase (γGT) 8-60 u/l

Albumin 35-50 g/l

Total protein 60-80 g/l

Other haematology

Erythrocyte sedimentation rate (ESR)

Men: < (age / 2) mm/hr

Women: < ((age + 10) / 2) mm/hr

Prothrombin time (PT) 10-14 secs

Activated partial thromboplastin time (APTT)
25-35 secs

Ferritin 20-230 ng/ml

Vitamin B₁₂ 200-900 ng/l

Folate 3.0 nmol/l

Reticulocytes 0.5-1.5%

Other biochemistry

Calcium 2.1-2.6 mmol/l

Phosphate 0.8-1.4 mmol/l

CRP < 10 mg/l

Thyroid stimulating hormone (TSH) 0.5-5.5
mu/l

Free thyroxine (T4) 9-18 pmol/l

Total thyroxine (T4) 70-140 nmol/l

Amylase 70-300 u/l

Uric acid 0.18-0.48 mmol/l

Arterial blood gases

pH 7.35 - 7.45

pCO₂ 4.5 - 6.0 kPa

pO₂ 10 - 14 kPa

Lipids

Desirable lipid values depend on other risk factors for cardiovascular disease, below is just a guide:

Total cholesterol < 5 mmol/l

Triglycerides < 2 mmol/l

HDL cholesterol > 1 mmol/l

LDL cholesterol < 3 mmol/l

[Q: 1] OnExamination - Cardiology

In the consideration of cardiac tamponade, which of the following statements is most true?

- 1- Bradycardia is common
- 2- Early diastolic descent (y descent) is exacerbated
- 3- Pulsus paradoxus is pathognomonic
- 4- Renal failure is a recognised complication
- 5- The apex beat is always absent

Answer & Comments

Answer: 4- Renal failure is a recognised complication

Tachycardia is common in the presentation of cardiac tamponade, and the apex beat is frequently palpable. The y descent is absent, though pulsus paradoxus may or may not be present.

Pulsus paradoxus is defined as an inspiratory systolic fall in arterial pressure of 10mmHg or more. Pulsus paradoxus may also be present in massive PE, haemorrhagic shock, COPD and severe hypotension. Renal failure is a recognised complication of tamponade.

[Q: 2] OnExamination - Cardiology

A 65-year-old male presents with arthralgia and sleep disturbance following the introduction of simvastatin. He has a history of hypertension and ischaemic heart disease for which he is receiving aspirin, atenolol and eprosartan together with simvastatin 40 mg od which has been introduced in the last one month. Previously, he had been taking atorvastatin but this was changed to simvastatin after he complained of arthralgia. Investigations reveal:

Creatine Phosphokinase (CPK) 156 iu/l (40-170)

Total Cholesterol 5.1 mmol/l (<5.2)

LDL-Cholesterol 3.1 mmol/l (<2.6)

Triglycerides 1.7 mmol/l (0.5-1.7)

HDL-Cholesterol 1.2 mmol/l (0.7-1.7)

Which is the most appropriate treatment for his lipid profile?

- 1- Ezetimibe
- 2- Fenofibrate
- 3- Nicotinic acid slow release
- 4- Omega-3 fatty acids
- 5- Rosuvastatin

Answer & Comments

Answer: 1- Ezetimibe

The primary treatment target in this case is a total cholesterol < 4 mmol/l and LDL - C < 2 mmol/l. Plasma triglyceride and HDL-C are already at the currently accepted target levels. This patient describes typical statin associated side effects which are generally a class effect and dose related. The most common adverse event with statin therapy is arthralgia or myopathy often with normal CPK levels. Myositis and rhabdomyolysis are rare statin associated myopathy side effects and are defined on the basis of CPK levels > 10X normal along with features of muscle pain and myoglobinuria (for rhabdomyolysis). Risk factors predisposing to statin myopathy include advanced age, trauma, thyroid dysfunction and concomitant medication that can raise statin bioavailability including amiodarone, verapamil and many other agents that are metabolised by the Cytochrome P450 enzyme system. Ezetimibe monotherapy produces reductions in TC and LDL-C of around 20% and since tolerability issues are likely to occur with another statin, ezetimibe is the best treatment option. Clinical trial data has demonstrated continuing event rate reduction to LDL-C levels below 2 mmol/l and a meta-analysis of lipid lowering trials has demonstrated a 1 mmol/l reduction in LDL-C is associated with a 23% RRR in CHD

events irrespective of baseline risk and the method of cholesterol reduction.

[Q: 3] OnExamination - Cardiology

A 68-year-old man has been very ill for months following the onset of chronic liver disease with hepatitis C infection. He experiences a sudden loss of consciousness and then exhibits hemiplegia on the right. A cerebral angiogram reveals lack of perfusion in the left middle cerebral artery distribution.

The most likely cardiac lesion to be associated with this finding is?

- 1- Acute rheumatic fever
- 2- Left atrial myxoma
- 3- Libman-Sacks endocarditis
- 4- Non-bacterial thrombotic endocarditis
- 5- Paradoxical thromboembolus

Answer & Comments

Answer: 4- Non-bacterial thrombotic endocarditis

Marantic endocarditis has platelet-fibrin thrombi that are prone to embolize. This form of non-infective endocarditis can be seen in persons who are very debilitated or who have a hypercoagulable state.

[Q: 4] OnExamination - Cardiology

A 67-year-old insulin dependent diabetic with a broad complex pulseless tachyarrhythmia (with a protected airway) has been defibrillated 3 times. He has just finished receiving 2 minutes of cardiopulmonary resuscitation and has received adrenaline.

Which of the following is the next step in the management of the arrest?

- 1- Adrenaline 1 mg
- 2- Amiodarone 300mg
- 3- DC shock
- 4- Lidocaine 100mg

- 5- Removal of oxygen and then DC shock

Answer & Comments

Answer: 2- Amiodarone 300mg

After 3 DC shocks and a further cycle of 2 mins of CPR the next step is Amiodarone 300mg intravenously and then a 4th shock. If amiodarone is not available lidocaine is a suitable alternative

[Q: 5] OnExamination - Cardiology

Which of the following statements concerning the treatment of acute myocardial infarction is correct?

- 1- A pansystolic murmur developing within the first 24 hours does not require further investigation.
- 2- Dipyridamole therapy reduces reinfarction within the first year.
- 3- Heparin is beneficial if given with streptokinase.
- 4- Prophylactic lidocaine given in the first 48 hours is effective in preventing ventricular fibrillation
- 5- Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality.

Answer & Comments

Answer: 5- Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality.

GISSI II revealed no survival advantage of heparin plus streptokinase in acute MI compared with strep alone. ISIS II revealed that dihydropyridine calcium antagonists were associated with increased cardiovascular risk after MI. Dipyridamole does not reduce risk. A newly discovered pansystolic murmur may signify acquired MR or VSD.

[Q: 6] OnExamination - Cardiology

Angina due to an imbalance between O_2 supply and demand without atherosclerosis would most likely be seen in which of the following circumstances?

- 1- aortic regurgitation
- 2- cardiac tamponade
- 3- pulmonary regurgitation
- 4- right heart failure
- 5- tricuspid regurgitation

Answer & Comments

Answer: 1- aortic regurgitation

Non-atherosclerotic angina would be associated with conditions such as thyrotoxicosis, aortic regurgitation, aortic stenosis, hypertrophic cardiomyopathy and anaemia to name but a few.

[Q: 7] OnExamination - Cardiology

A 57-year-old female school cleaner is undergoing investigation for breathlessness.

All the following would be in keeping with a diagnosis of constrictive pericarditis except

- 1- Elevated JVP with absent y descent
- 2- Peripheral oedema
- 3- Orthopnoea
- 4- Ascites
- 5- Previous cardiac surgery

Answer & Comments

Answer: 1- Elevated JVP with absent y descent

Constrictive pericarditis produces an elevated JVP, with prominent x and y descent. Pulsus paradoxus occurs less frequently than in tamponade. Other signs include oedema, ascites, hepatomegaly, orthopnoea and dyspnoea. Constriction can be a subtle cause of dyspnoea after cardiac surgery.

[Q: 8] OnExamination - Cardiology

A 62-year-old male is admitted with an inferior myocardial infarction and receives thrombolysis, aspirin, atenolol, simvastatin and lisinopril. His ECG shows good ST segment resolution. The following day he develops some pain in the legs and a dusky discolouration of the lower limbs. On closer examination there is a diffuse petechial rash over the lower legs particularly the feet but all peripheral pulses are palpable. Investigations reveal:

Haemoglobin	13.3 g/dl	(12-16)
Platelets	145 x 10^9 /L	(140-450)
White cell count	12.1 x 10^9 /L	(4-10)
Neutrophils	6.5 x 10^9 /L	(2-7)
Lymphocytes	3.5 x 10^9 /L	(1-3.5)
Eosinophils	1.2 x 10^9 /L	(0.3-0.6)
IgE antibody	3 mg/dl	(<2mg/dl)

Which of the following is the most likely cause for his current problems?

- 1- Allergic reaction to thrombolysis
- 2- Aspirin allergy
- 3- Cholesterol emboli
- 4- Peripheral vascular disease
- 5- Polyarteritis nodosa

Answer & Comments

Answer: 3- Cholesterol emboli

This patient is an arteriopath as suggested by the acute MI and one day after thrombolysis develops this petechial rash in the lower limbs with raised white cell count - marked eosinophilia and raised IgE. Rather than allergy, this suggests cholesterol embolisation syndrome. This case report provides all the information on cholesterol embolisation following treatment of IHD.

[Q: 9] OnExamination - Cardiology

A 29-year-old female presents with acute right sided weakness. She has one child aged 4 years and had two spontaneous abortions in the past. After the birth of her child she developed a DVT and required three months anticoagulation with warfarin. Examination revealed a right hemiparesis. A CT head scan showed a left middle cerebral artery territory infarct.

What is the most likely finding on echocardiography?

- 1- Atrial septal defect
- 2- Bicuspid aortic valve
- 3- Left atrial myxoma
- 4- Normal appearances
- 5- Ventricular septal defect

Answer & Comments

Answer: 4- Normal appearances

This patient has a prothrombotic tendency suggestive of the lupus anticoagulant with recurrent abortions, previous DVT and now she has developed a left hemiparesis. This has occurred off warfarin and it is highly unlikely to be due to any right to left transference of clot. It is more likely to be due to spontaneous infarct related to the thrombophilia and her heart is likely to be normal.

[Q: 10] OnExamination - Cardiology

A 59-year-old male has been discharged from hospital following an uncomplicated admission with myocardial infarction and treated with stenting. His therapy at discharge included aspirin 75 mg daily, ramipril 10mg daily, atenolol 50 mg daily and simvastatin 40 mg daily.

On subsequent review, 1 month after discharge he is well and unaware of any chest pain. His blood pressure is 134/78 mmHg and he has a resting heart rate is 66 bpm. There

are no abnormalities on auscultation of the heart or chest.

Investigations reveal:

Cholesterol	4.6 mmol/l
Triglyceride	0.8 mmol/l
Glucose	5.6 mmol/l
U+E	Normal

Which of the following therapies added to his current treatment regime would be expected to reduce mortality still further?

- 1- Amlodipine
- 2- Ezetimibe
- 3- Furosemide
- 4- Omega-3 fatty acids
- 5- Vitamin E

Answer & Comments

Answer: 4- Omega-3 fatty acids

Of the agents suggested, Omega-3 fatty acids (in essence fish oils) have been demonstrated in the GISSI-prevenzione study to reduce mortality in this particular group of patients with coronary artery disease on standard treatment by a further approximate 20% for all cause mortality and 40% reduction in sudden deaths vs controls. Whereas, vitamin E therapy was associated with no significant differences. It appears that Omega-3 Fish oils may have a benefit beside improving lipid profile with increases in HDL and reductions in triglyceride, as it has been suggested that they may confer some anti-arrhythmic effect. Short acting calcium antagonists early after MI possibly increase mortality and certainly have no beneficial effect. Similarly, Furosemide has no data to indicate improved outcome. Ezetimibe, which inhibits cholesterol reabsorption has no data to indicate a survival advantage.

[Q: 11] OnExamination - Cardiology

A 55-year-old man presents with gynaecomastia. He is receiving treatment for Heart failure and gastro-oesophageal reflux.

Which of the following drugs that he takes is most likely to be responsible for his gynaecomastia?

- 1- Amiloride
- 2- Carvedilol
- 3- Furosemide
- 4- Ranitidine
- 5- Ramipril

Answer & Comments

Answer: 4- Ranitidine

Like cimetidine, ranitidine is also associated with gynaecomastia. Omeprazole is associated with gynaecomastia although this is disputed. None of the other agents are associated. Other causes of gynaecomastia include spironolactone, digoxin, cimetidine, LHRH analogues and finasteride.

[Q: 12] OnExamination - Cardiology

A 60-year-old man had a myocardial infarction 6 weeks ago. He is taking aspirin 75 mg/day and metoprolol 50mg 2/day. During a routine follow-up Exercise Test he has a 20 beat run of non-sustained VT. He achieved stage 4 of the Bruce protocol and 92 % of his target heart rate. The non-sustained VT occurred halfway through Stage 2. ST segments were normal during the study.

What is the definitive investigation?

- 1- Coronary angiography.
- 2- Echocardiogram.
- 3- Electrophysiological study.
- 4- Thallium exercise scan.
- 5- 24 hour Holter monitor.

Answer & Comments

Answer: 3- Electrophysiological study.

Post MI VT is most commonly due to scar tissue. It may also be related to ischaemia but no signs of ischaemia were induced. The DEFINITIVE investigation would be EPS due to the fact that if this were scar related VT the site could be localised and even possibly ablated. If not then an ICD implantation may be warranted on MADIT criteria if LV dysfunction exists. Angio + Thallium may inform us of significant CAD but not offer us a solution to the problem. Echo would not be of much use apart from assessing LV function although in this patient one might assume that LV function is pretty good achieving stage IV of Bruce protocol, thus ECHO, although required would not be the definitive test and would be down on the selection list. There is no need for Holter as the VT has already been recorded.

The reference for MADIT is AmJCardiol 1997;79(suppl 6A):16-7. It was stopped early in 1996 by the steering committee due to extremely positive results in the ICD group. As a consequence it was only published in abstract form. However, MADIT-2 published in the NEJM (Ref: N Engl J Med 2002; 346:877-883, Mar 21, 2002) showed a 5.6% 20 month absolute survival benefit in patients with LV dysfunction (EF<30%) post MI treated prophylactically with an ICD.

[Q: 13] OnExamination - Cardiology

A 34-year-old man presented for an insurance medical. He was symptom free, but clinical examination suggested a small ventricular septal defect.

Which one of the following findings was most likely to have been present?

- 1- An early diastolic murmur
- 2- A short systolic murmur at the left sternal edge

- 3- A systolic murmur maximal at the apex
- 4- A systolic murmur with thrill at the left sternal edge
- 5- Fixed splitting of the second heart sound

Answer & Comments

Answer: 4- A systolic murmur with thrill at the left sternal edge

Typically, a small VSD generates a pansystolic murmur at the LSE accompanied by a thrill. The murmur may be heard at the apex but is usually loudest at the LSE. Very small defects may generate an early/late systolic murmur. Fixed splitting of the heart sounds usually accompanies atrial septal defects.

[Q: 14] OnExamination - Cardiology

A 75 year-old woman presents with a two month history of episodic loss of vision in her right eye. Her ECG was normal and carotid ultrasound reveal a 50% stenosis of the right internal carotid artery.

What is the most appropriate treatment for this patient?

- 1- Aspirin
- 2- Carotid endarterectomy
- 3- Dipyridamole
- 4- Prednisolone
- 5- Warfarin

Answer & Comments

Answer: 1- Aspirin

The patients experience TIA's of the form of amaurosis fugax due to carotid artery stenosis. Carotid endarterectomy is only indicated if the stenosis is 70-99%. Aspirin is the treatment of choice and good control of all vascular risk factors. Warfarin is not indicated unless the patient is in AF.

[Q: 15] OnExamination - Cardiology

A 74-year-old woman with longstanding hypertension and rheumatoid arthritis presented with dyspnoea. On examination she was in atrial fibrillation and was normotensive.

The jugular venous pressure was elevated. She had bilateral pitting lower limb oedema and ascites. Her echocardiogram showed normal left ventricular systolic function and bi-atrial enlargement.

What is the most likely diagnosis?

- 1- Constrictive pericarditis
- 2- Hypertensive heart disease
- 3- Hypothyroidism
- 4- Lymphatic obstruction
- 5- Pulmonary fibrosis

Answer & Comments

Answer: 1- Constrictive pericarditis

The combination of SOB, atrial fibrillation, lower limb oedema, ascites, raised JVP and bi-atrial enlargement with normal systolic ventricular function is typical of constrictive pericarditis. Hypertension is another cause of diastolic dysfunction but this lady is normotensive and hypertension would not create such dramatic clinical signs.

Further ECHO examination would reveal peak systolic and diastolic values decreasing with inspiration, and impaired diastolic function.

Constrictive pericarditis is associated with Rheumatoid Arthritis. Constrictive pericarditis can be a difficult clinical diagnosis. Read a case review of constrictive pericarditis.

[Q: 16] OnExamination - Cardiology

A 70-year-old female is reviewed in clinic after having had an anterior MI. Her echo reveals some left ventricular impairment. You are contemplating the

addition of a beta blocker to current therapy which consists of bendroflumethiazide, aspirin and simvastatin.

Which of the following Beta blockers should be avoided?

- 1- Bisoprolol
- 2- Carvedilol
- 3- Metoprolol
- 4- Propranolol
- 5- Sotalol

Answer & Comments

Answer: 5- Sotalol

Sotalol may prolong the QT interval and leads to a risk of ventricular arrhythmias. This can be a particular risk in individuals with hypokalaemia. The thiazide diuretic bendroflumethiazide predisposes to hypokalaemia due to its action on inhibiting potassium reabsorption in the distal tubules of the nephrons.

[Q: 17] OnExamination - Cardiology

A 75-year-old female is noted to have sustained hypertension with a blood pressure of 196/80 mmHg.

Which of the following is the most appropriate strategy for this patient?

- 1- ACE inhibitors would be contra-indicated in association with a creatinine above 150 micromols/l (50-100)
- 2- Antihypertensive therapy would be associated with only a minor reduction in risk of stroke in this age group
- 3- Beta blockers are less effective in this age group than in younger patients
- 4- Doxazosin would be the most appropriate initial treatment for this patient
- 5- The patient would only require a non-pharmacological approach as diastolic blood pressure is normal

Answer & Comments

Answer: 3- Beta blockers are less effective in this age group than in younger patients

This patient has isolated systolic hypertension with a persistent systolic BP over 140mmHg and diastolic BP below 90, this is associated with increased risk of stroke and coronary events in those over 60 years. This systolic hypertension should be lowered if persistent and is not responding to non-pharmacological measures, with calcium-channel blockers and thiazides as drugs of first choice. Elderly patients have a higher absolute cardiovascular risk than younger individuals and therefore benefit more from control of blood pressure. ACE inhibitors are not contraindicated when the serum creatinine is greater than 150umol/L but should be commenced under specialist supervision. There is evidence that beta blockers maybe less effective in elderly patients.

[Q: 18] OnExamination - Cardiology

A 51-year-old man with type 2 diabetes and no previous history of CHD presents at annual review. Currently he is taking metformin 500 mg bd, aspirin 75 mg od, perindopril 4 mg od and simvastatin 20 mg od. He has a blood pressure of 140/72 mm/Hg. On examination, his blood pressure is 140/72 mmHg, he has background diabetic retinopathy and has a peripheral sensory neuropathy to light touch in the feet. Investigations reveal:

HbA1c	7.1 %	(<6)
Total cholesterol	3.9 mmol/l	(<5.2)
Triglyceride	2.5 mmol/l	(0.5-1.7)
HDL-Cholesterol	0.8 mmol/l	(0.7-1.7)
LDL-Cholesterol	2.1 mmol/l	(<2.6)

Which is the most appropriate treatment for this man's dyslipidaemia?

- 1- Cholestyramine
- 2- Ezetimibe

- 3- Fenofibrate
- 4- No other treatment required
- 5- Rosuvastatin

Answer & Comments

Answer: 3- Fenofibrate

This patient's TC and LDL-C are at the currently advocated target levels. Current treatment targets advocate desirable HDL-C levels > 1 mmol/l and plasma TG < 1.7 mmol/l in subjects at risk of CVD. The FIELD study assessed the effects of fenofibrate therapy on CV mortality in patients with type 2 diabetes. Although the primary end-point of CV mortality was not achieved partly due to high use of non study lipid lowering therapies (statin use was much higher in placebo group 34% vs 18% in fenofibrate), although the composite endpoint of major CVD events was significantly reduced with fenofibrate. Furthermore, at any given LDL or TC level, reduced HDL-C is associated with an increased CHD risk. Fenofibrate increases HDL-C by 10 - 15% and reduces plasma TG by 15 - 20%. Concomitant fibrate-statin use is associated with an increased risk of myopathy so safety and tolerability evaluation of combination therapy is important. When evaluating a patient with hypertriglyceridaemia, secondary causes need to be considered these include hypothyroidism and poorly controlled diabetes as well as excess alcohol intake.

[Q: 19] OnExamination - Cardiology

A 69-year-old woman presented with an ulcer over the left ankle, which had developed over the previous 9 months. She had a history of right deep vein thrombosis five years previously. On examination she had a superficial slough-based ulcer, 6cms in diameter, over the medial malleolus with no evidence of cellulitis.

Which one of the following is the most appropriate next investigation?

- 1- ankle-brachial pressure index
- 2- bacteriological swab of the ulcer
- 3- bilateral lower limb arteriogram
- 4- right leg venogram
- 5- venous duplex ultrasound scan

Answer & Comments

Answer: 1- ankle-brachial pressure index

It has been reported that venous ulcerations are the most common type of ulcer affecting the lower extremities. The probable underlying cause of venous congestion, which may promote ulceration, is venous insufficiency. The treatment of venous ulceration is control of oedema, treating any infection, and compression. However, compressive dressings or devices should not be applied if the arterial circulation is impaired. It is thus important to identify any arterial disease, and ankle-brachial pressure index is a simple way of doing this. One may then progress to lower limb arteriogram if indicated. There is no clinical sign of infection, and although a bacterial swab would help to rule out pathogens within the ulcer, arterial insufficiency is the more important issue. If there is a clinical suspicion of DVT then duplex (or rarely a venogram) is indicated to decide on the indication for warfarin.

[Q: 20] OnExamination - Cardiology

A 62-year-old man suffered a myocardial infarction six weeks ago. He was taking soluble Aspirin 75mg daily and Metoprolol 50mg twice a day. During a follow up exercise test he had a 20 beat run of non-sustained ventricular tachycardia.

What is the next most appropriate investigation?

- 1- Coronary angiography
- 2- Echocardiography
- 3- Electrophysiological study

- 4- Thallium exercise scan
- 5- 24 hour Holter monitoring

Answer & Comments

Answer: 3- Electrophysiological study

The finding of NSVT puts this man at risk of sudden cardiac death. Structural heart disease would put him in a high risk group for sudden cardiac death, and in the clinical scenario described above, EPS is the most relevant next step. Holter monitoring would add little further information, prognostically at least. EPS would be required to assess whether the VT is inducible, which would have a bearing on therapy and potentially ablation could be used. ECHO adds little. Angiography would also be required to assess coronary circulation, given the likelihood of ischaemia-induced arrhythmia.

[Q: 21] OnExamination - Cardiology

Left atrial myxoma may be associated with all except-

- 1- Sudden death
- 2- A mid systolic click
- 3- Systemic emboli
- 4- Left atrial dilatation
- 5- Adrenal hyperplasia

Answer & Comments

Answer: 2- A mid systolic click

Atrial myxoma in the heart make up 50% of primary cardiac tumours. They are most common in the left atrium arising from a pedicle on the fossa ovalis. On third present with emboli, a third with systemic inflammation (ESR elevated in 1/3) and a third are asymptomatic when detected. The can intermittently flop through the mitral valve, and cause a mid-diastolic click (tumour plop) when they stop moving. Elevated left atrial pressures cause dilatation. Syncope can occur

due to obstruction. They are more common in women.

Carney complex is a familial multiple neoplasia and lentiginosis syndrome associated with primary adrenal hypercortisolism, lentigenes and naevi of the skin, various tumours including myxoma.

[Q: 22] OnExamination - Cardiology

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations. The ECG reveals a Supraventricular tachycardia and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patients paroxysmal supraventricular tachycardia?

- 1- Amiodarone
- 2- Disopyramide
- 3- Flecainide
- 4- Metoprolol
- 5- Verapamil

Answer & Comments

Answer: 4- Metoprolol

Tachyarrhythmias may increase during pregnancy although the causes are not entirely clear. Regarding the termination of acute SVT adenosine appears to be safe in pregnancy. In the case of the prevention of recurrent SVT then verapamil or beta blockers have data supporting their use. Current AHA/EHA criteria for the treatment of SVTs in pregnancy do suggest using metoprolol (level of evidence 1B) rather than Verapamil (C) although recommend avoiding the former in the first trimester.

[Q: 23] OnExamination - Cardiology

Which one of the following is a

recognised feature of abetalipoproteinaemia?

- 1- a high serum cholesterol
- 2- palmar xanthomas
- 3- advanced atherosclerotic vascular disease
- 4- abnormal red blood cell morphology
- 5- Severe mental retardation

Answer & Comments

Answer: 4- abnormal red blood cell morphology

Acanthocytes are seen in abetalipoproteinaemia.

Retinitis pigmentosa is seen in abetalipoproteinaemia. Neurodegenerative changes are seen such as ataxia but IQ is normal.

**[Q: 24] OnExamination - Cardiology**

A 14-year-old boy presents with hypertension.

Which of the following statements concerning hypertension in the young is true?

- 1- Sodium nitroprusside is useful for the long-term treatment of severe cases.
- 2- Headache is the usual presenting feature.
- 3- It is defined as systolic blood pressure above the 99th centile for age.
- 4- Abnormalities are frequently seen on DMSA scan.
- 5- Aortic coarctation is the commonest secondary cause.

Answer & Comments

Answer: 4- Abnormalities are frequently seen on DMSA scan.

D Sodium nitroprusside is useful only in the short term, as cyanide levels accumulate with time. Hypertension is usually diagnosed incidentally, and is defined as systolic blood pressure >95th centile for age. Secondary

causes are usually due to renal abnormalities, with reflux associated scarring being the commonest renal disease. This will cause abnormalities on DMSA scan. Coarctation of the aorta is the commonest non-renal cause, with pheochromocytoma/neuroblastoma, congenital adrenal hyperplasia, Cushing Syndrome and steroid therapy being rarer causes.

**[Q: 25] OnExamination - Cardiology**

A 35-year-old male presents with chest pain on exertion. On examination she has yellow discolouration of her palmar creases and a diagnosis of remnant Hyperlipidaemia (type III hyperlipidaemia) is made.

What is the cause of this hyperlipidaemia?

- 1- Apo CIII homozygosity
- 2- Apo E-2 homozygosity
- 3- LCAT deficiency
- 4- LDL receptor deficiency
- 5- Lipoprotein lipase deficiency

Answer & Comments

Answer: 2- Apo E-2 homozygosity

Remnant hyperlipidaemia is associated with hypercholesterolaemia,

hypertriglyceridaemia, palmar xanthomata and early onset of cardiovascular disease. The genotype of the condition is apo E-2/E-2 and occurs with a frequency of 1:100. LDL receptor deficiency is associated with familial hypercholesterolaemia. Lipoprotein lipase deficiency is rare and associated with marked hypertriglyceridaemia.

**[Q: 26] OnExamination - Cardiology**

A 43- year-old gentleman develops chest pain 7 minutes after fiberoptic bronchoscopy. The procedure had been performed without sedation following an

intratracheal injection of 5 ml 2.5% cocaine solution and xylocaine spray to the pharynx for topical anaesthesia. ECG showed an evolving anterior myocardial infarction.

Which of the following would you prefer for his management?

- 1- Beta blockers
- 2- Nitrates
- 3- Percutaneous transluminal coronary angioplasty
- 4- Thrombolysis with rt-PA
- 5- Thrombolysis with streptokinase

Answer & Comments

Answer: 2- Nitrates

The underlying mechanism here is vasoconstriction, not thrombosis. Cocaine is cardiotoxic and its use has been linked to coronary artery spasm, angina, myocardial infarction, arrhythmias, sudden cardiac death, and myocardial contraction bands, which might act as a substrate for arrhythmias. It is important to avoid β -blockers in treating cocaine induced chest pains or acute myocardial infarctions as this may result in unopposed α adrenergic action with worsening coronary spasm. Calcium channel antagonists or nitrates should be administered as early as possible.

[Q: 27] OnExamination - Cardiology

A 66-year-old man has developed chronic renal failure with a serum urea of 60 mmol/L and creatinine of 650 micromol/L. Auscultation of the chest reveals a friction rub over the cardiac apex.

He is most likely to have a pericarditis that is termed?

- 1- Constrictive
- 2- Fibrinous
- 3- Hemorrhagic

- 4- Purulent
- 5- Serous

Answer & Comments

Answer: 2- Fibrinous

The uraemia leads to exudation of fibrin onto the epicardial and pericardial surfaces. Haemorrhagic pericarditis is more typical of tuberculosis or metastatic tumour. Serous pericarditis is more typical of collagen vascular diseases.

[Q: 28] OnExamination - Cardiology

A 60-year-old man presents with an inferior MI and receives thrombolysis. 4 hours following initial presentation he becomes acutely breathless. His ECG demonstrates sinus tachycardia (rate 108bpm) with T wave inversion inferiorly. His ST segments are normal. On examination his JVP is elevated at 5 cm. Chest was clear to auscultation. Following 80 mg of Furosemide he deteriorates. His BP is now 80/60 and his urine output over the last 2 hours is 5 mls.

What is the best investigative measure?

- 1- Arterial Blood Gases
- 2- Central Venous Pressure Monitoring
- 3- Chest X-Ray
- 4- Echocardiography
- 5- Pulmonary Capillary Wedge Pressure Monitoring

Answer & Comments

Answer: 5- Pulmonary Capillary Wedge Pressure Monitoring

The scenario is that of a right ventricular MI. The treatment in this situation is fluid to increase LVEDP and not furosemide, which worsens the situation. The best way to determine if adequate fluid is being given is using a Swan Ganz catheter to monitor PCWP

(a surrogate for Left Atrial pressure). While CVP monitoring is also helpful, CVP is increased in LV failure due to infarct as well so would not help to monitor treatment. Echocardiography would show a small volume LV with a dilated RV.

[Q: 29] OnExamination - Cardiology

75 year-old man with a history of anterior MI is taking amiodarone 400mg/day for history of VT. He has a prolonged QT interval on his ECG.

What is the most appropriate management?

- 1- Admit to hospital for monitoring.
- 2- Atenolol.
- 3- Change amiodarone to flecainide.
- 4- Continue with amiodarone.
- 5- Discontinue amiodarone immediately.

Answer & Comments

Answer: 5- Discontinue amiodarone immediately.

In iatrogenic long QT which is what this is likely to be, it is safer to stop the offending drug rather than add further drugs on board (eg B-blockers even though Atenolol is used for long QT). Flecainide is clearly contraindicated in this situation (CAST study).

[Q: 30] OnExamination - Cardiology

A 62-year-old male who is being treated for stable angina presents with muscle aches and pains. He has been taking simvastatin 40 mg daily, atenolol 50 mg daily together with aspirin 75 mg daily for approximately two years. Recently he was admitted for an episode of acute coronary syndrome and a number of other therapies were added. You suspect a statin related myopathy and a CPK concentration is 820 iu/l (50-200).

Which of the following is most likely to be responsible for the precipitation of his statin related myopathy?

- 1- Bisoprolol
- 2- Clopidogrel
- 3- Diltiazem
- 4- Omega-3 fatty acids
- 5- Spironolactone

Answer & Comments

Answer: 3- Diltiazem

Statin associated myopathy occurs in up to 5% of those treated with statins and may be exacerbated by the co-prescription of other drugs such as Calcium channel blockers, macrolide antibiotics, fibrates, amiodarone and Grapefruit juice! Whilst patients may tolerate a statin extremely well, a myopathy or rhabdomyolysis can quite easily be precipitated by the addition of these agents.

[Q: 31] OnExamination - Cardiology

Which of the following concerning congenital heart disease is correct?

- 1- ASD is the commonest malformation at birth
- 2- congenital complete heart block is usually associated with Anti-Ro antibodies in the mother
- 3- Ebstein's anomaly is associated with maternal exposure to lithium carbonate
- 4- Hypoplastic left heart syndrome is characterised by a large, dilated left ventricle
- 5- Osteogenesis imperfecta is associated with aortic stenosis

Answer & Comments

Answer: 3- Ebstein's anomaly is associated with maternal exposure to lithium carbonate

A VSD is the commonest at 30%, ASD is 10%. Aortic regurgitation may be a feature of Osteogenesis imperfecta. Ebstein's anomaly is associated with maternal LiCO₃ use if exposed in the first trimester. In the vast majority of cases of neonates with complete heart block the cause is unknown but in the minority it may be caused by autoimmune disease, particularly Anti-Ro antibodies, in the mother. LV Hypoplasia occurs when the left sided chambers fail to develop and blood enters the systemic circulation from the right ventricle via the pulmonary artery and a patent ductus arteriosus.

[Q: 32] OnExamination - Cardiology

Which of the following may be responsible for a hypokalaemic hypertension

- 1- Non-classical congenital adrenal hyperplasia
- 2- Barter's syndrome
- 3- Diabetic nephropathy
- 4- Liddle's syndrome
- 5- Type IV renal tubular acidosis

Answer & Comments

Answer: 4- Liddle's syndrome

Liddle's syndrome is typically associated with hypokalaemic hypertension and low renin and aldosterone concentrations - the so called pseudo-hyperaldosteronism. Barter's syndrome is associated with hypokalaemia though hypertension is not a feature. In type IV RTA, there is a hyporeninaemic hypoaldosteronism, which may also be produced with diabetic nephropathy. Hence hyperkalaemia is more typical.

[Q: 33] OnExamination - Cardiology

A 27-year-old fit and healthy male has an ECG as part of his medical examination for employment as a pilot. The ECG reveals a

delta waves indicating Wolf Parkinson White Syndrome.

What is the most appropriate treatment for this patient?

- 1- Atenolol
- 2- Flecainide
- 3- Radio-frequency ablation
- 4- Reassurance
- 5- Verapamil

Answer & Comments

Answer: 4- Reassurance

WPW is a relatively common cardiological abnormality occurring in approx 0.1 to 3% of the population. It is due to an accessory pathway and although most subjects are asymptomatic, there is the small risk of sudden death from tachyarrhythmias (<0.6%). Treatment is based on risk stratification. One of the pointers is symptomatology and also electrophysiological studies. Generally, in an asymptomatic individual it is uncertain whether any intervention or indeed any EPS is required. Radiofrequency ablation is the treatment of choice in those identified to be at risk.

[Q: 34] OnExamination - Cardiology

A 51-year-old businessman complains of dyspnoea on exertion. He recently returned from a business trip to the USA. He has distant heart sounds on auscultation of the chest. A chest radiograph reveals that there is a thin rim of calcification surrounding the cardiac outline.

Which of the following conditions is most likely responsible for these findings?

- 1- Uraemia
- 2- Tuberculosis
- 3- Group B coxsackie virus
- 4- Sarcoidosis

5- Metastatic carcinoma

Answer & Comments

Answer: 2- Tuberculosis

The most likely diagnosis is a constrictive pericarditis. The most probable cause for this is previous tuberculous infection which may have occurred many years previously. Acute TB would usually cause a constrictive pericarditis secondary to a pericardial effusion, but is not normally associated with calcification. Uraemia can cause a constrictive pericarditis, as can a pericardial malignancy, and coxsackie virus (secondary to a pericarditis) but calcification would be unusual. Sarcoid can cause both pericardial as well as restrictive cardiomyopathy but calcification would be unusual.

[Q: 35] OnExamination - Cardiology

A 35-year-old shop worker presents with pain in her calves which develops after 50 yards of walking. The pain settles with rest. On examination she has yellow discolouration of her palmar creases. Her fasting lipid profile reveals:

Cholesterol 9.6 mmol/l (less than 5)

Triglycerides 7.3 mmol/l (less than 2)

What is the likely diagnosis?

- 1- Chylomicronaemia
- 2- Familial hyperlipidaemia
- 3- Hypoalphalipoproteinaemia
- 4- Type III hyperlipidaemia
- 5- Type IV hyperlipidaemia

Answer & Comments

Answer: 4- Type III hyperlipidaemia

Remnant hyperlipidaemia (Type III hyperlipidaemia) is associated with elevated fasting cholesterol (usually >7.8mmol/l) and triglyceride levels (usually >5.0mmol/l). It

presents with palmar xanthomata and early onset cardiovascular disease (CHD, PVD and CVA). Hypoalphalipoproteinaemia is a rare, familial condition and is associated with low HDL. Chylomicronaemia is associated particularly with hypertriglyceridaemia and not with large elevations in cholesterol. Familial hyperlipidaemia is due to LDL-receptor deficiency, and is not associated with elevated triglyceride levels.

[Q: 36] OnExamination - Cardiology

Which of the following findings is the most specific for a diagnosis of myocardial infarction?

- 1- an akinetic area of LV wall motion on ECHO
- 2- elevated cardiac enzymes
- 3- evolution of Q waves on ECG
- 4- history of severe chest pain
- 5- ST elevation on ECG

Answer & Comments

Answer: 3- evolution of Q waves on ECG

Cardiac enzymes may be elevated in PE, Renal failure and raised ST segments associated with pericarditis. Akinetic wall motion on the echo may occur with any regional disease process like amyloid etc. The evolution of Q waves is the most suggestive of an infarct.

[Q: 37] OnExamination - Cardiology

A 30-year-old intravenous drug abuser develops acute aortic regurgitation due to infective endocarditis.

Which of the following is not typical of acute aortic regurgitation?

- 1- normal cardiac output
- 2- decrescendo diastolic murmur
- 3- hypotension
- 4- mitral valve pre-closure
- 5- peripheral vasodilatation

Answer & Comments

Answer: 5- peripheral vasodilatation

Findings that would be typical include large pulse volume, increased pulse pressure, a decrescendo murmur and a low diastolic blood pressure. Vasoconstriction not dilatation is typically found.

[Q: 38] OnExamination - Cardiology

A 65-year-old female presents with a four hour history of fatigue and palpitations. On examination she is vomiting, and is noted to have a slight tremor, some lid lag and has an irregularly irregular pulse of 140 per minute, with some fine basal crackles. ECG confirms atrial fibrillation with a rate of approximately 130 per minute. Thyroid function tests show: Free T₄ 31.8 pmol/l (9-22) TSH 0.05 mu/l (0.5-4.5)

Which of the following is the most appropriate initial treatment for this patient?

- 1- Anticoagulation
- 2- DC cardioversion
- 3- IV amiodarone
- 4- IV digoxin
- 5- IV Metoprolol

Answer & Comments

Answer: 4- IV digoxin

Atrial fibrillation occurs in 5-15% of patients with thyrotoxicosis. The most appropriate immediate treatment for this patient with fast atrial fibrillation and a degree of failure would be digoxin either IV which acts within 30 minutes or oral. Although patients may be relatively resistant to digoxin the drug should still be used in association with failure. AF associated with Thyrotoxicosis often spontaneously reverts to sinus rhythm when euthyroidism is restored, hence cardioversion should be withheld until antithyroid medication has been successful. All patients

with atrial fibrillation associated with thyrotoxicosis should be anticoagulated due to the high risk of thromboembolism. However, in this case it is first important to control the fast AF. Beta blockers would probably not be the best option here in view of the heart failure. If this were absent beta blockers IV would be the best choice.

[Q: 39] OnExamination - Cardiology

Which ONE of the following statements is true about the Austin Flint murmur?

- 1- It is associated with a loud first heart sound.
- 2- It is an early sign of aortic regurgitation
- 3- It can be distinguished from the murmur of mitral stenosis by absence of presystolic accentuation
- 4- It is due to partial closure of the anterior leaflet of the mitral valve
- 5- It does not occur in aortic incompetence secondary to an aortitis

Answer & Comments

Answer: 4- It is due to partial closure of the anterior leaflet of the mitral valve

The Austin Flint murmur is a low frequency mid/late diastolic murmur which may show pre-systolic accentuation and is virtually indistinguishable from that of mitral stenosis. It is due to partial closure of the anterior leaflet of the mitral valve by the regurgitant jet. There is no correlation between presence of murmur and severity of AR, or aetiology. The first heart sound is normal but in severe cases, it may be absent.

[Q: 40] OnExamination - Cardiology

A 75-year-old lady presents with sudden breathlessness and palpitations. On examination, she was observed to have an irregular heart beat with rate of 140 bpm, BP 150/84 and normal heart sounds. On

auscultation of the chest, Fine basal crepitations are heard. An ECG confirms AF and an old inferior MI. She is anticoagulated with heparin and given diuretics. Her heart rate remains rapid.

What is the most appropriate management of the lady's AF?

- 1- DCCV
- 2- IV amiodarone
- 3- IV betablocker
- 4- IV digoxin
- 5- Oral quinidine therapy

Answer & Comments

Answer: 2- IV amiodarone

The key to this question is that the patient has clinical signs of pulmonary oedema with fast AF. In this age group AF is poorly tolerated and often leads to pulmonary oedema even in the presence of a relatively normal LV. NICE have published guidance on the treatment of AF. The primary aim here should be rate control which is best achieved with Amiodarone in this situation. Digoxin even when used IV is suggested to have too slow an onset of action to merit its use. Betablockers can also be used but due to the fact that they are negatively inotropic may complicate the acute pulmonary oedema. Emergency DCCV is not required as there is no haemodynamic compromise (BP) yet. Amiodarone allows DCCV to remain an option if haemodynamic compromise develops. It may be possible to cardiovert this patient in the long term depending on duration in AF, LA size, LVF, LVID etc. Check this reference out - M Bilal Iqbal, Anil K Taneja, Gregory Y H Lip, and Marcus Flather. Recent developments in atrial fibrillation BMJ, Jan 2005; 330: 238 - 243

[Q: 41] OnExamination - Cardiology

What is Troponin?

- 1- A component of thick filaments

- 2- A component of thin filaments
- 3- A myosin heavy chain
- 4- A myosin light chain
- 5- A substance produced by pulmonary vascular endothelium

Answer & Comments

Answer: 2- A component of thin filaments

Troponin is a component of thin filaments (along with actin and tropomyosin), and is the protein to which calcium binds to accomplish this regulation. Troponin has three subunits, TnC, TnI, and TnT. When calcium is bound to specific sites on TnC, the structure of the thin filament changes in such a manner that myosin (a molecular motor organized in muscle thick filaments) attaches to thin filaments and produces force and/or movement. In the absence of calcium, tropomyosin interferes with this action of myosin, and therefore muscles remain relaxed.

[Q: 42] OnExamination - Cardiology

In a normal heart, the oxygen saturation of a sample of blood taken from a catheter in the pulmonary capillary wedge position should be equal to a sample from which of the following?

- 1- coronary sinus
- 2- femoral artery
- 3- pulmonary artery
- 4- right atrium
- 5- right ventricle

Answer & Comments

Answer: 2- femoral artery

Pulmonary capillary wedge normal values reflect pressures and saturations of the left side of the heart. Consequently wedge pressures are between 6-12 mmHg and the

saturations of blood taken from the wedged source reflects blood in the pulmonary vein and hence high sats similar to that seen in the femoral artery.

[Q: 43] OnExamination - Cardiology

A 29-year-old female with Turner syndrome is referred by the GP concerned about her blood pressure which he has found to be persistently elevated at between 140-160/90 mmHg. On examination she is noted to have a blood pressure of 148/92 mmHg, with no radio-femoral delay and no murmur audible.

Which of the following is the most likely cause of her hypertension?

- 1- Coarctation of the aorta
- 2- Essential hypertension
- 3- Primary hyperaldosteronism
- 4- Renal artery stenosis
- 5- Single horseshoe kidney

Answer & Comments

Answer: 2- Essential hypertension

Hypertension is quite common in Turner syndrome (10%) and is typically idiopathic - essential. In a small proportion causes can include coarctation of the aorta and renal dysfunction due to horseshoe kidney. In this case, essential hypertension is the most likely cause but in the absence of specific features of coarctation this would again be the most appropriate option.

[Q: 44] OnExamination - Cardiology

A 29-year-old male is admitted with a one hour history of severe central chest pain associated with vomiting. It transpires that he used cocaine three hours ago. His Blood pressure is 142/74 mmHg and a pulse of 110 beats per minute regular. His ECG reveals 3 mm ST segment elevation in leads V2-5.

Which of the following is the most appropriate treatment for this patient?

- 1- Abciximab
- 2- Angiography +/- PTCA
- 3- Isoket infusion
- 4- Low molecular weight heparin
- 5- Tissue plasminogen activator (rtPA)

Answer & Comments

Answer: 2- Angiography +/- PTCA

Cocaine is a drug of widespread abuse and remains one of the commonest causes of acute myocardial infarction in men below 35 years of age. The aetiology of cocaine induced MI is speculated to be related to coronary artery spasm as many patients do not have overt coronary artery disease. Consequently guidelines recommend angiography with PTCA where appropriate in these patients.

[Q: 45] OnExamination - Cardiology

A 60-year-old female presents with a 4 week history of low grade fever, dyspnoea and fatigue. Two months ago she received a prosthetic valve replacement for mitral regurgitation. On examination she has a temperature of 37.7°C. At trans-oesophageal echocardiography vegetations are seen.

A clinical diagnosis of prosthetic valve endocarditis is made.

Which of the following is the most likely causative organism?

- 1- Actinomyces
- 2- Candida albicans
- 3- Enterococci
- 4- Staphylococcus aureus
- 5- Streptococcus viridans

Answer & Comments

Answer: 4- Staphylococcus aureus

Generally there are two identifiable modes of prosthetic valve endocarditis. The first occurs within the first year after surgery affecting 0.7-3% of cases and is often due to staphylococci. Late endocarditis observed after two years post surgery is found in 0.5 - 1% of cases and is typically due to streptococci- typically group A haemolytic otherwise known as strep viridans.

[Q: 46] OnExamination - Cardiology

A 55-year-old male with ischaemic heart disease is seen for review. He reports that he has developed some muscle aches and pains and you attribute this to a myalgia associated with simvastatin. His Creatinine kinase is within the normal range. However, his dyslipidaemia is still sub-optimal and you wish to add in a further agent.

Which of the following agents would not be an appropriate additional therapy for this patient in view of his presentation?

- 1- Cholestyramine
- 2- Ezetimibe
- 3- Gemfibrozil
- 4- Nicotinic acid
- 5- Omega-3 fatty acids

Answer & Comments

Answer: 3- Gemfibrozil

This patient presents with a probable statin induced myalgia which often improves with time. Sometimes stopping therapy briefly or re-introducing a different statin may resolve the myalgia. Statin induced myositis is relatively uncommon occurring in approximately 0.1-0.2%. But, the risk of myositis and the potentially fatal rhabdomyolysis is increased with Gemfibrozil, in prone subjects in combination with a statin and as such should be avoided. Additional agents could include Omega-3 fatty acids and Ezetimibe. Nicotinic acid is less used due to

problems with flushing though can be useful particularly in hypertriglyceridaemia. Cholestyramine can also be used.

[Q: 47] OnExamination - Cardiology

Which of the following statements regarding B-type natriuretic peptide (BNP), is correct?

- 1- BNP is synthesised predominantly in the cerebrovascular circulation
- 2- The stimulus for BNP release is increased ventricular pressure load
- 3- BNP synthesis is decreased by thyroid hormone
- 4- BNP causes arterial and venous smooth muscle vasodilatation
- 5- BNP augments sodium reabsorption in the kidney

Answer & Comments

Answer: 4- BNP causes arterial and venous smooth muscle vasodilatation

The ventricular myocardium is the primary site of BNP synthesis. The stimulus for BNP release is myocyte stretch, rather than transmural pressure load. BNP synthesis is increased by thyroid hormones as well as glucocorticoids, endothelin-1, angiotensin-II and tachycardia, independent of the haemodynamic effects of these factors. In the kidney, BNP causes increased GFR and inhibition of sodium reabsorption leading to natriuresis and diuresis. BNP leads to reduced blood pressure, and reduced pre-load due to relaxing effects on vascular smooth muscle. For an informative review refer to Lancet 2003;362:316-22.

[Q: 48] OnExamination - Cardiology

A 60-year-old man takes atenolol for hypertension.

Which of the following side effects is he most likely to be aware of two hours after taking atenolol?

- 1- Fatigue
- 2- Hesitancy of micturition
- 3- Nausea
- 4- Orthostatic hypotension
- 5- Somnolence

Answer & Comments

Answer: 1- Fatigue

Atenolol is a water soluble beta blocker, taken once daily and is not associated with drowsiness/sleep disturbance like the lipid-soluble β -blockers. It is not associated with nausea or hesitancy of micturition and would be unlikely to produce significant postural hypotension in a hypertensive subject. However, fatigue is a frequent side effect which typically is felt two hours and beyond after taking the drug.

[Q: 49] OnExamination - Cardiology

A 70-year-old male with a 5 year history of type II diabetes mellitus presents for annual review with a blood pressure of 188/88 mmHg. Clinical examination was normal. An ECG reveals evidence of left ventricular hypertrophy.

Which one of the following drugs is the most appropriate treatment for this patient's hypertension?

- 1- Atenolol
- 2- Amlodipine
- 3- Bendroflumethiazide
- 4- Doxazosin
- 5- Valsartan

Answer & Comments

Answer: 5- Valsartan

Regarding the British Hypertensive Society guidelines and NICE guidelines on the treatment of BP in T2D, this elderly male diabetic has isolated systolic hypertension associated with LVH (LVH being defined as a complication of hypertension). Evidence would support the use of a calcium channel blocker and/or ACEi as first line (see ab-cd rule in BMJ 2004;328:634-40). In a diabetic patient with evidence of nephropathy or any patient with LVH there is compelling evidence to suggest that ACEi or angiotensin II receptor blockers should be first line treatment for hypertension.

[Q: 50] OnExamination - Cardiology

An 87-year-old woman was referred to clinic with a two-month history of alternating constipation and diarrhea, night sweats and fatigue. The patient was not sure if she had lost any weight.

On examination she appeared thin and pale. Pulse 80/minute and regular. A systolic murmur was audible at the apex, radiating to the axilla. No diastolic murmurs were heard.

Investigations

Blood cultures: positive

Transthoracic echocardiogram revealed a vegetation on the mitral valve

What is the most likely causative organism in this case?

- 1- Coagulase-negative Staphylococcus
- 2- Staphylococcus aureus
- 3- Streptococcus bovis
- 4- Streptococcus mitis
- 5- Streptococcus viridans

Answer & Comments

Answer: 3- Streptococcus bovis

This patient clearly has endocarditis! In addition to the symptoms that might be attributed to endocarditis (fatigue, night

sweats), she also has a history of altered bowel habit that is very suggestive of an underlying malignancy. *Streptococcus bovis* is a normal commensal of the GI tract. However, *S. bovis* bacteraemia and endocarditis has a strong association with GI malignancy.

Coagulase-negative staphylococcal endocarditis is exceptionally rare in native valve endocarditis, though is the commonest cause of prosthetic valve endocarditis in the postoperative period. *Staphylococcus aureus* endocarditis is typically the result of a focus of *Staphylococcal* infection (e.g skin abscess). *Streptococcus mitis* endocarditis. Viridans streptococci (which include *S. mitis*) are normal commensals of the oropharynx and GI tract; endocarditis is usually associated with poor dental hygiene; overall, *Streptococcus viridans* accounts for ~40% of cases of endocarditis.

[Q: 51] OnExamination - Cardiology

A paper describes a new diagnostic test for myocardial infarction. You want to know what proportion of patients who are classified as not having had a myocardial infarction by the test will actually not have had a myocardial infarction.

Which one of the following measurements would indicate this?

- 1- accuracy
- 2- negative predictive value
- 3- positive predictive value
- 4- sensitivity
- 5- specificity

Answer & Comments

Answer: 2- negative predictive value

The proportion of 'true negatives' not having had a MI correctly identified by this test is called the Negative predictive value and refers to the number accurately identified to not have MI by the new test over the number

without MI identified by the test + those wrongly identified as not having had an MI. specificity is the number without MI accurately predicted. Sensitivity refers to the number correctly identified with MI by the new test. A positive predictive value refers to the number accurately identified with MI by the test over the number accurately identified with MI + those wrongly identified with MI.

[Q: 52] OnExamination - Cardiology

A 40-year-old man received an orthotopic cardiac transplant 7 years ago to treat a dilated cardiomyopathy. Since that time he has been healthy, with no episodes of rejection or infection. Over the next year, however, he develops fatigue with exercise. He has worsening pedal edema and orthopnea. On physical examination, his vital signs are Temperature 36.3°C, Pulse 78, Respiratory rate 16, and BP 130/70 mm Hg. There are no murmurs, rubs, or gallops audible. Bibasilar crackles in the lungs are audible.

Which of the following conditions is most likely to account for these findings?

- 1- Angiosarcoma
- 2- Coronary arteriopathy
- 3- Mitral valvular stenosis
- 4- Myocarditis
- 5- Pulmonary hypertension

Answer & Comments

Answer: 2- Coronary arteriopathy

By 5 years following cardiac transplantation, nearly all patients have some degree of small coronary vascular narrowing. Myocarditis is unlikely to be present in the absence of rejection or infection.

[Q: 53] OnExamination - Cardiology

A 17-year-old female presents after

taking an overdose of her grandmother's medication.

Investigations revealed:

Serum potassium 6 mmol/L (3.5-4.9)

Which one of the following drugs is the most likely cause of this abnormality?

- 1- Aspirin
- 2- Digoxin
- 3- Fluoxetine
- 4- Omeprazole
- 5- Propranolol

Answer & Comments

Answer: 5- Propranolol

Betablockers, particularly propranolol, in overdose can cause hyperkalaemia by transmembrane shifts. It is useful to think of the opposite - beta-agonists such as salbutamol are far more widely known to cause hypokalaemia.

Overdose of digoxin therapy most commonly manifests as rhythm disturbance, and may be exacerbated by hyper- or hypokalaemia. Salicylate overdose causes metabolic acidosis and respiratory alkalosis.

[Q: 54] OnExamination - Cardiology

A 65-year-old was advised to start oral digoxin at a dose of 250 µg daily. His physician explained that the full effect of this treatment would not be apparent for at least a week.

Which one of the following pharmacokinetic variables did the physician use to give this explanation?

- 1- bioavailability
- 2- half-life
- 3- plasma protein binding
- 4- renal clearance
- 5- volume of distribution

Answer & Comments

Answer: 2- half-life

Digoxin follows first order kinetics and has a half life of 1.6 days in a patient with normal renal function. 65% of the drug absorbed remain in the system after one day. Subsequent doses gradually accumulate until a steady state is achieved after 4 to 5 days.

[Q: 55] OnExamination - Cardiology

Which of the following is first to rise following myocardial infarction?

- 1- Creatine Phosphokinase
- 2- CK-MB
- 3- Lactate dehydrogenase
- 4- Myoglobin
- 5- Troponin I

Answer & Comments

Answer: 4- Myoglobin

Myoglobin, is a sensitive indicator of muscle injury and is first to rise following MI within 2 hrs but is non specific. Troponin and CK-MB both begin to rise approximately 3 hrs after MI. Both are far more specific of Myocardial injury. LDH begins to rise approximately 12 hrs after MI.

[Q: 56] OnExamination - Cardiology

A 55-year-old man with Type 2 Diabetes Mellitus and Ischaemic Heart Disease has been researching the Internet! He asks your opinion on Laser Transmyocardial Revascularisation.

Which of the following statements about this technique is true?

- 1- avoids the need for major surgery
- 2- damages the endocardium
- 3- involves destruction of coronary stenoses

- 4- is of particular use in severe proximal coronary artery disease
- 5- stimulates collateral vessel formation

Answer & Comments

Answer: 2- damages the endocardium

Open chest surgery is undertaken during which laser holes are punched from the epicardial surface into areas of suspected ischaemic or hibernating ventricular muscle. The process is not fully understood. The epicardial end of the hole heals up leaving artificial channels communicating with the ventricular chamber and effectively forming new coronary vessels.

Laser transmyocardial revascularisation has potential in distal disease such as in Diabetes - Angioplasty and CABG are useful in proximal disease.

[Q: 57] OnExamination - Cardiology

Which of the following antiarrhythmic drugs may be used in the treatment of long QT syndrome?

- 1- Amiodarone
- 2- Atenolol
- 3- Flecainide
- 4- Propofanone
- 5- Sotalol

Answer & Comments

Answer: 2- Atenolol

Beta blockers are the mainstay of treatment in long QT syndrome. The most commonly used drugs are propranolol and nadolol but metoprolol and atenolol are also used. Implantable Cardioverter-Defibrillators are the most effective treatment in high risk cases. The others drugs may produce a prolongation of the QT interval exacerbating risk of polymorphic VT and Torsades de pointes. For

a list of drugs see QTdrugs.org. For an example of long QT syndrome

[Q: 58] OnExamination - Cardiology

Elevation of the jugular venous pressure during inspiration is most likely to be found in which of the following situations?

- 1- a normal physical exam
- 2- cardiac tamponade
- 3- constrictive pericarditis
- 4- dilated cardiomyopathy
- 5- myocarditis

Answer & Comments

Answer: 3- constrictive pericarditis

Kussmaul's sign (a rise in jugular venous pressure on inspiration - the opposite to normal) is seen in both Constrictive Pericarditis and Pericardial Tamponade but it is more likely to be present in the former. However, neither of these are the commonest cause ... can anyone name that

[Q: 59] OnExamination - Cardiology

A 27-year-old woman presented with a history of sudden onset right-sided weakness and dysphasia lasting 8 hours. She had returned to the UK from Australia 2 days previously. There was no significant past medical history and physical examination was normal. Chest X-ray, ECG and a CT head scan were all normal.

Which one of the following investigations is most likely to reveal the underlying cause of this episode?

- 1- Carotid doppler ultrasonography
- 2- Cerebral angiography
- 3- MRI of head
- 4- Transoesophageal echocardiography
- 5- Transthoracic echocardiography

Answer & Comments

Answer: 4- Transoesophageal echocardiography

The history here suggests a lower limb deep vein thrombosis with peripheral embolus through a patent foramen ovale, leading to a left sided cerebrovascular event. This is termed the paradoxical embolus - so-called because a thromboembolus arising from the venous circulation can end up in the systemic circulation.

Transoesophageal echocardiography is the investigation of choice to investigate for a patent foramen ovale, although transthoracic echocardiography with contrast may be an alternative.

[Q: 60] OnExamination - Cardiology

A 45-year-old HIV-seropositive man attended the outpatient clinic for the results of a fasting serum lipid test. He had been diagnosed with HIV disease two years previously and was started on highly active antiretroviral therapy. One year after commencing antiretrovirals, his CD4 count had risen from 10 cells/mm³ to 120 cells/mm³ with an undetectable viral load. His current medications consisted of zidovudine, lamivudine lopinavir, aciclovir, fluconazole and co-trimoxazole.

Fasting lipid profile revealed:

Serum cholesterol 4.1 mmol/L (<5.2)

Serum triglyceride 18.2 mmol/L (0.5 - 1.7)

Which of the following medications is most likely to be responsible for these results?

- 1- Co-trimoxazole
- 2- Fluconazole
- 3- Lamivudine
- 4- Lopinavir
- 5- Zidovudine

Answer & Comments

Answer: 4- Lopinavir

Lipodystrophy, lipoatrophy and alterations in serum lipid values have been observed in patients with HIV disease taking highly active antiretroviral therapy. Elevated serum lipid levels have been associated with premature coronary artery disease. Hypertriglyceridemia is also thought to contribute to central fat deposition, and insulin resistance that is also seen in these patients.

Abnormalities of serum lipid levels are likely to be multifactorial in patients with HIV disease, but appear much commoner in patients taking protease inhibitors. Isolated hypertriglyceridemia can occur in HIV disease in the absence of protease inhibitors, but extremely high serum triglycerides have been documented in some patients treated with these drugs.

If the elevation in lipid levels is modest, measures such as dietary modification and exercise may be tried first. Omega-3 fish oils may also be beneficial in reducing modestly-elevated serum triglycerides. In refractory cases, or where there is extreme isolated hypertriglyceridemia, a fibrate should be used. In addition, patients with HIV disease may also have elevated serum lipid levels due to familial hyperlipidaemia.

[Q: 61] OnExamination - Cardiology

A 65-year-old is investigated for dyspnoea and is shown to have an ejection fraction of 45% on echocardiography.

How is left ventricular ejection fraction calculated?

- 1- Cardiac output/stroke volume
- 2- End systolic volume/end diastolic volume
- 3- End diastolic volume/end systolic volume
- 4- End diastolic volume/stroke volume
- 5- Stroke volume/end diastolic volume

Answer & Comments

Answer: 5- Stroke volume/end diastolic volume

The left ventricle pumps only a fraction of the blood it contains. The ejection fraction is the amount of blood pumped (stroke volume=end diastolic volume - end systolic volume) divided by the amount of blood the ventricle contains (end diastolic volume). A normal ejection fraction is more than 55% of the blood volume.

[Q: 62] OnExamination - Cardiology

A 45-year-old man is admitted with central crushing chest pain, sweating and vomiting of 1 hour duration. He is conscious with a pulse rate of 100bpm and a blood pressure of 200/125mmHg. An ECG shows > 2mm ST elevation in leads I, II, aVL and V2-6. CBC: normal, U & E: normal. Troponin T: 100ng/ml. Apart from the presence of xanthelasma (+) there are no other positive findings on clinical examination. He is given oxygen, aspirin, morphine and intravenous 5mg atenolol.

What will you do next?

- 1- CABG
- 2- Nitroprusside infusion
- 3- PTCA
- 4- Thrombolysis with rt-PA
- 5- Thrombolysis with streptokinase

Answer & Comments

Answer: 3- PTCA

It is a case of acute myocardial infarction. Typically thrombolysis should be carried out in the absence of any contraindications. BP > 200/120 is one of the contraindication. So the next appropriate management in this case is urgent angioplasty for extensive anterolateral infarction. BP control should follow suit.

[Q: 63] OnExamination - Cardiology

A 74-year-old man presented with intermittent chest pain at rest.

Which one of the following would most strongly suggest that the pain was due to myocardial ischaemia?

- 1- Associated dyspnoea
- 2- Coexistent claudication
- 3- Past history of cigarette smoking
- 4- Radiation of pain to the jaw
- 5- Relief of pain by sublingual nitrate

Answer & Comments

Answer: 4- Radiation of pain to the jaw

Nitrates may relieve the pain of oesophageal spasm, as well as that of myocardial ischaemia. Associated dyspnoea may be due to anxiety.

Coexistent claudication suggests the presence of peripheral vascular disease. A past history of cigarette smoking is a risk factor for the development of cardiovascular disease.

However, the most specific feature of the given options which suggests that the pain is myocardial ischaemia, is the radiation to the jaw, which is relatively specific for pain of myocardial ischaemia.

[Q: 64] OnExamination - Cardiology

Which ONE of the following is associated with Marfan's syndrome?

- 1- Autosomal recessive inheritance
- 2- increased upper : lower body ratio
- 3- Mental retardation
- 4- Pulmonary stenosis
- 5- Retinal detachment

Answer & Comments

Answer: 5- Retinal detachment

Marfan's syndrome is an autosomal dominant condition associated with ocular abnormalities such as upwards lens dislocation and retinal detachment. Aortic regurgitation may be a finding and aneurysmal dilatation is a feature. Upper to lower body ratio (head to symphysis pubis : Symphysis pubis to toes) is decreased in Marfan Syndrome.

[Q: 65] OnExamination - Cardiology

A randomised double-blind placebo controlled study of a cholesterol-lowering drug for the primary prevention of coronary heart disease was conducted. It had a five-year follow up period.

The results showed an absolute risk of myocardial infarction in the group-receiving placebo during was 10 per cent. The relative risk reduction of those given the cholesterol lowering medication was 0.8.

Approximately what number of patients will need to be treated with the drug for five years to prevent one myocardial infarction?

- 1- 10
- 2- 13
- 3- 15
- 4- 20
- 5- 23

Answer & Comments

Answer: 2- 13

This is a question concerning Number Needed to Treat (NNT). The calculation involves a little arithmetic. The absolute risk of MI in the group is a pretty high 10% i.e of 1000 patients on placebo 100 will have MI over 5 years. The relative risk reduction is stated as 0.8 i.e 80%. Therefore, if you treat 1000 patients for 5 years with the cholesterol lowering agent you'll get only 20 MIs. Thus, for 1000 patients treated you'll get 80 fewer MIs. Thus Number Needed to Treat to get 1 fewer MI is 1000/80

= 12.5. Or, if you're any good at remembering formulae you can remember the following: -
 1. Relative risk reduction (RRR) = Absolute risk reduction (ARR) / Control event rate (CER)
 2. Numbers needed to treat (NNT) = 1 / Absolute risk reduction (ARR)
 You can then just insert the figures into these formulae. The control (or placebo) event rate (CER) is 10% or 0.10. The relative risk reduction is 0.80. Inserting these figures into the above formulae....
 $RRR = ARR / CER$
 $0.80 = ARR / 0.10$
 $ARR = 0.80 * 0.10 = 0.08$
 Then the NNT can be calculated by
 $NNT = 1 / ARR = 1 / 0.08 = 12.5$.
 However, if algebra isn't your thing you could try working with real numbers. Imagine a group of 100 patients (it makes the maths easier) In the control (or placebo group) 10% (or 10 patients) suffered an MI. The relative risk reduction is 0.8 or 80%. Therefore, in the treatment group, there would be a reduction in events by 80% (of 10 patients) = 8 patients. The number of patients suffering an MI in the treatment would therefore be 10 - 8 = 2 patients. It can therefore be said that treating 100 patients with the new drug would result in 8 fewer MIs. The number needed to treat to prevent one MI would be 100/8 = 12.5 patients.

[Q: 66] OnExamination - Cardiology

Which of the following infections is least likely to cause myocarditis?

- 1- Coxsackie virus
- 2- Diphtheria
- 3- Chagas Disease
- 4- Syphilis
- 5- Toxoplasmosis

Answer & Comments

Answer: 4- Syphilis

Quaternary syphilis involves the cardiovascular system commonly in form of ascending aortic aneurysm and aortic regurgitation. Diphtheria, coxsackie virus,

Chagas disease and toxoplasmosis are all associated with myocarditis.

[Q: 67] OnExamination - Cardiology

In Down syndrome, which is the commonest congenital heart defect?

- 1- Atrial septal defect
- 2- Atrioventricular septal defect
- 3- Patent ductus arteriosus
- 4- Tetralogy of Fallot
- 5- Ventricular septal defect

Answer & Comments

Answer: 2- Atrioventricular septal defect

50% of Down syndrome births have congenital heart disease. Defects in order of decreasing frequency are: B, E, C, D and A.

[Q: 68] OnExamination - Cardiology

A 21-year-old man with Hypertrophic Cardiomyopathy presents in clinic with dizzy spells but has not had any syncopal episodes.

Which of the following, if present, would be indicate an increased risk of sudden cardiac death?

- 1- Asymmetric septal hypertrophy with maximum wall thickness of 2.1 cm
- 2- Blood Pressure drop of 20mmHg during peak exercise tolerance testing
- 3- Left Ventricular Outflow Tract Gradient of 80 mmHg
- 4- Systolic Anterior Movement of the mitral valve on echocardiography
- 5- Worsening exertional angina

Answer & Comments

Answer: 2- Blood Pressure drop of 20mmHg during peak exercise tolerance testing

Patients with Hypertrophic Cardiomyopathy (HCM) are at increased risk of sudden cardiac death due to VF/VT. The five poor prognostic markers which are predictive of sudden cardiac death are:

1. Syncope
2. Family History of HCM and sudden cardiac death
3. Maximum Left Ventricular Wall Thickness >3cm
4. BP drop during peak exercise on stress testing
5. Documented runs of Non-Sustained VT on 24 hour tape.

LVOT obstruction causes symptoms and can lead to deterioration of LV function but does not predict sudden cardiac death. Asymmetric Septal Hypertrophy is a feature of HCM, in order to assess the risk for sudden cardiac death a detailed echocardiogram with measurements of the maximum left ventricular wall thickness is required. Systolic anterior movement of the mitral valve is often seen on echocardiogram and is thought to be the mechanism behind the left ventricular outflow tract obstruction.

[Q: 69] OnExamination - Cardiology

Which of the following compounds has a vasodilating effect?

- 1- Antidiuretic hormone
- 2- Calcitonin
- 3- Endothelin
- 4- Renin
- 5- Somatostatin

Answer & Comments

Answer: 2- Calcitonin

ADH acts on the Vasopressor receptors to cause vasoconstriction. Endothelin is also a

vasoconstrictor as is renin. Somatostatin is also recognised to produce vasoconstriction of the splanchnic system.

[Q: 70] OnExamination - Cardiology

A 70-year-old woman is referred with hypertension. Despite lifestyle advice, her GP notes blood pressure recordings averaging 170/100 mmHg. She was commenced on an antihypertensive but one month later complains of symptoms suggestive of postural hypotension.

Which one of the following is most likely to be responsible for this side effect?

- 1- amlodipine
- 2- atenolol
- 3- bendroflumethiazide
- 4- doxazosin
- 5- lisinopril

Answer & Comments

Answer: 2- atenolol

Odd question as all the agents can cause postural hypotension but one might think that the causative agent would be an α -blocker. However, the evidence suggests the contrary as amongst all the classes a β -blocker is most associated with postural hypotension in the elderly. So, the correct answer is a β -blocker yet it's a lottery to determine if the RCP would have this down as their right answer. Other agents particularly associated with postural hypotension include the centrally acting agents like alpha Methyl Dopa and reserpine.

[Q: 71] OnExamination - Cardiology

You are asked to see a patient in the Intensive Care Unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms. A right heart catheter reveals that the mixed venous O_2 saturation is 70%; the pulmonary capillary wedge O_2 saturation is

97%. The haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

- 1- her cardiac output is decreased
- 2- her cardiac output is normal
- 3- her heart is normal
- 4- she has high-output failure
- 5- she is in shock due to a non-cardiac cause

Answer & Comments

Answer: 2- her cardiac output is normal

The right heart and wedge catheters show normal sats, the latter suggesting that she has good pulmonary oxygenation and so these features would argue against any failure - decreased or high output failure and would certainly argue against shock of any sort. Therefore, one cannot go as far as to say that she has a normal heart, so the best response (by a process of elimination) is that she has a normal output.

[Q: 72] OnExamination - Cardiology

A 78-year-old female is referred by her GP with high blood pressure. Over the last three months her blood pressure is noted to be around 180/80 mmHg. She has a body mass index of 25.5 kg/m², is a non-smoker.

There are no features to suggest a secondary cause for her hypertension.

Which of the following is the most appropriate treatment for her blood pressure?

- 1- Alpha-Blocker
- 2- Angiotensin Converting Enzyme (ACE) Inhibitor
- 3- Angiotensin Blocker
- 4- Beta-blocker
- 5- Calcium channel blocker

Answer & Comments

Answer: 5- Calcium channel blocker

This patient has isolated systolic hypertension (systolic BP >160 and diastolic BP <90) which is the typical hypertension in the elderly population and is associated with a greater risk than combined systolic/diastolic hypertension. Based upon studies such as SHEP and Syst-Eur, guidelines suggest treatment with either Calcium antagonists or diuretics.

[Q: 73] OnExamination - Cardiology

A 23-year-old male presents with a deep vein thrombosis. He has no past medical history but his mother has suffered from deep vein thromboses.

Which of the following is likely to be found on haematological assessment?

- 1- Factor V Leiden mutation
- 2- Protein S deficiency
- 3- Protein C deficiency
- 4- Antithrombin deficiency
- 5- Lupus anticoagulant

Answer & Comments

Answer: 4- Antithrombin deficiency

Antithrombin deficiency is an autosomal dominant condition present in 0.02 - 1.1% of the population and is found in 4% of subjects that present with a thromboembolism.

Factor V Leiden is a possibility although seems less likely as the inheritance pattern seems more likely to be AD. Similarly as the son had a DVT this would be far less likely with FVLeiden than ATIII as thrombosis is more often precipitated in females on the OCP.

See (Simioni P, Sanson BJ, Prandoni P, et al. Thromb Haemost 1999 Feb;81(2):198-202) who show that "The annual incidences of total and spontaneous venous thromboembolic

events in carriers of AT, PC or PS defects (n=181) were 1.01% and 0.40%, respectively, as compared to 0.10% and 0.04% in non-carriers, respectively (relative risks both 10.6). In carriers of Factor V Leiden (n= 224), the annual incidences of total and spontaneous venous thromboembolism were 0.28% and 0.11%, respectively, as compared to 0.09% and 0.04% in non-carriers, respectively (relative risks 2.8 and 2.5)."

See also "Risk of a first venous thrombotic event in carriers of a familial thrombophilic defect. The European Prospective Cohort on Thrombophilia (EPCOT)."

[Q: 74] OnExamination - Cardiology

A post-marketing surveillance study of a new heart failure therapy to the market was carried out on 10,000 subjects who had completed clinical trials.

Which one of the following most accurately reflects the information generated from such a study?

- 1- Adverse events profile
- 2- Cost benefit analysis
- 3- Cost effectiveness
- 4- Comparative therapeutic efficacy
- 5- Drug potency

Answer & Comments

Answer: 1- Adverse events profile

Post-marketing surveillance/observational studies (phase IV studies) generally are designed to assess the potential side effects of new drugs but under everyday conditions and with a minimum of intervention. In contrast to the randomized controlled trials, PMS typically include patients from more extreme age groups, patients with comorbidity or other risk factors. In order to cover a wide spectrum of patients and to observe rare events with sufficiently high probability, PMS enroll a large number of patients, typically several

thousands. Comparative efficacy has already been undertaken in Phase III studies (RCTs) but can also be undertaken as part of specific RCT studies later in the drugs development and potency usually in phase I and II studies.

[Q: 75] OnExamination - Cardiology

A 60-year-old man's echocardiogram shows a dilated left ventricular cavity with the remainder of the other chamber sizes normal.

The most likely diagnosis is which of the following?

- 1- aortic regurgitation
- 2- aortic stenosis
- 3- hypertensive heart disease
- 4- mitral regurgitation
- 5- mitral stenosis

Answer & Comments

Answer: 1- aortic regurgitation

No echocardiographic data are provided regarding the valves but a volume overload as with AR would result in dilatation of the left ventricle. MR, AS, and hypertension would have the effect of causing hypertrophy and a smaller LV cavity. MS would have little effect on LV dimensions.

[Q: 76] OnExamination - Cardiology

Which of the following is true regarding the coronary circulation?

- 1- Adenosine is an important mediator of metabolic vasodilation.
- 2- Coronary blood flow is independent of myocardial oxygen consumption due to autoregulation.
- 3- Coronary blood flow within a normal range of blood pressure is primarily determined by perfusion pressure.
- 4- Increased myocardial O₂ demand is met primarily by increasing O₂ extraction.

- 5- The vasodilatory reserve of the epicardium and endocardium is equivalent under normal physiologic conditions.

Answer & Comments

Answer: 1- Adenosine is an important mediator of metabolic vasodilation.

Adenosine has a particularly short half-life, acts on specific adenosine cell surface receptors (A₁ and A₂) and is inactivated by adenosine deaminase. It results in coronary vasodilatation and depression of sinus node automaticity and AVN conduction.

Coronary blood flow is dependent on myocardial oxygen consumption and is pretty independently maintained throughout the ranges of blood pressure. Increasing O₂ demands are met by increased blood supply facilitated by vasodilatation brought about by adenosine production.

[Q: 77] OnExamination - Cardiology

A 24-year-old woman develops infective endocarditis involving the aortic valve. She receives a porcine bioprosthesis because of her desire to have children and not to take anticoagulant medication. After ten years, she must have this prosthetic valve replaced.

Which of the following pathologic findings in the bioprosthesis has most likely led to the need for replacement?

- 1- Calcification with stenosis
- 2- Dehiscence
- 3- Infective endocarditis
- 4- Strut failure
- 5- Thrombosis

Answer & Comments

Answer: 1- Calcification with stenosis

The bioprosthesis has the advantage of not requiring anticoagulation, but it does not wear well with time, and typically must be replaced within 5 to 10 years.

[Q: 78] OnExamination - Cardiology

A 74-year-old patient with a history of ischaemic heart disease presents with shortness of breath. He is finding difficulty mobilising any further than around his home. An ECHO demonstrates an ejection fraction of approximately 20%. He is on maximal drug therapy for heart failure, and is not thought to have an infective chest exacerbation. The ECG demonstrates sinus rhythm, with a rate of 75/min and widened QRS complexes.

What is the most appropriate treatment option?

- 1- Addition of Perhexiline therapy
- 2- Palliation as an inpatient with PRN morphine
- 3- Referral for implantable defibrillator
- 4- Referral for biventricular pacing
- 5- Referral for cardiac transplant

Answer & Comments

Answer: 4- Referral for biventricular pacing

This patient by definition has NYHA III heart failure. The CARE-HF study of heart failure patients has shown a 37% reduction in the primary endpoint of death and cardiovascular hospitalization and a reduction of 36% in all-cause mortality compared with control. Control patients were treated with maximal medical therapy only, and follow-up was a mean of 29 months. Examination of the COMPANION study demonstrates a 40% reduction in the risk of death or hospitalization from HF, and a 36% reduction in death from any cause, after implantation of biventricular pacing wires with a defibrillator. It may be that in the very near future we will be implanting biventricular pacing devices,

with defibrillator actions, in those patients to the subject groups included in these studies. The indications for implantation devices in these studies were low ejection fraction, dyssynchrony on the ECG (widened QRS), and NYHA III/IV. Perhexiline therapy may become standard therapy in this patient subgroup in the future, but as yet there is no mortality or morbidity evidence to support its widespread use.

[Q: 79] OnExamination - Cardiology

A 73-year-old male is referred with palpitations. On 24 hr ambulatory ECG monitoring he is shown to have paroxysmal atrial fibrillation and is treated with amiodarone.

Through blockade of which of the following receptors is the antiarrhythmic effect of amiodarone most attributed?

- 1- Alpha receptors
- 2- Beta receptors
- 3- Calcium channels
- 4- Potassium channels
- 5- Sodium channels

Answer & Comments

Answer: 4- Potassium channels

Amiodarone is a class III antiarrhythmic and as such is used in many supra and ventricular arrhythmias. Its antiarrhythmic effects are due mostly to the inhibition of the rapid component of the delayed potassium rectifier IKr channel (as with sotalol) but also an effect on the slow component. However, it is also recognised to have a mild alpha blocking effects, beta-blocking effects and calcium channel blocking effects although these are less responsible for the antiarrhythmic effects.

[Q: 80] OnExamination - Cardiology

A 35-year-old woman presents with

fever, rigors, malaise and weight loss. She had undergone prosthetic valve replacement 1 month before. C3 level was reduced and echocardiography showed small vegetations.

Which microorganism is most likely to be responsible for this?

- 1- Candida
- 2- Coxiella burnetii
- 3- Staphylococcus aureus
- 4- Staphylococcus epidermidis
- 5- Streptococcus viridans

Answer & Comments

Answer: 4- Staphylococcus epidermidis

Prosthetic valve endocarditis arising within 2 months of valve surgery is generally the result of intraoperative contamination of the prosthesis or a bacteraemia postoperative complication. The nosocomial nature of these infections is reflected in their primary microbial causes: coagulase-negative staphylococci (Staphylococcus epidermidis), S. aureus, facultative gram-negative bacilli, diphtheroids, and fungi. The oral cavity, skin, and upper respiratory tract are the respective primary portals for the viridans streptococci, staphylococci, and HACEK organisms (Haemophilus, Actinobacillus, Cardiobacterium, Eikenella, and Kingella) causing community-acquired native valve endocarditis. Streptococcus bovis originates from the gastrointestinal tract, where it is associated with polyps and colonic tumors, and enterococci enter the bloodstream from the genitourinary tract.

[Q: 81] OnExamination - Cardiology

A 70-year-old male is referred by his GP for management of recently diagnosed congestive heart failure. The patient has a history of poorly controlled hypertension. Over the last three months he has been aware of deteriorating shortness of breath, fatigue,

and orthopnea. Over the last month he had been commenced on Digoxin (62.5 micrograms daily), Furosemide (80 mg daily), and amiloride 10 mg.

On examination he has a pulse of 96 bpm regular, a blood pressure of 132/88 mmHg. His JVP was not raised, he had some scattered bibasal crackles on auscultation with a displaced apex beat in the anterior axillary line, 6th intercostal space. Auscultation of the heart revealed no murmurs and he had peripheral oedema to the mid tibia.

Investigations showed:

Serum sodium 144 mmol/L

Serum potassium 3.5 mmol/L

Serum urea 17 mmol/L

Serum creatinine 175 umol/L

Serum digoxin 0.7 ng/mL (therapeutic range 1.0-2.0)

One month previously his urea had been 11 mmol/L and creatinine 110 micromol/L. An ECG reveals left ventricular hypertrophy and Chest X-ray shows cardiomegaly and calcified aorta.

What is the most appropriate next step in management?

- 1- Add an ACE inhibitor to the current regimen
- 2- Add atenolol at a dose of 25mg daily
- 3- Increase digoxin to 0.25 mg daily
- 4- Increase furosemide to 80 mg twice daily
- 5- Maintain on current therapy.

Answer & Comments

Answer: 1- Add an ACE inhibitor to the current regimen

This patient would be classified as probably NYHA grade III heart failure (dyspnoeic at rest). With the persisting symptoms despite 80mg of furosemide, guidelines would initially suggest the addition of an ACE inhibitor. Although there has been a mild decline in his

U+Es since the introduction of therapy this would not be a contra-indication to the use of ACEis. There is no evidence that increasing a dose of digoxin above 62.5 micrograms in a patient in sinus rhythm would have any added benefit. Although β -blockers would be of further benefit in this patient, it is important first to establish him on ACEi and then introduce β -blockers like carvedilol, metoprolol or bisoprolol in a small dose and gradually increase.

[Q: 82] OnExamination - Cardiology

A 75-year-old male is admitted with chest pain and dyspnoea. His troponin T is 0.5 (NR <0.02 ng/ml). His pain subsides and he is generally well, although dyspnoea restricts his mobilisation. He is unable to manage the stairs, but can mobilise solely around the ward. Whilst being monitored his telemetry demonstrates short runs of non sustained ventricular tachycardia, associated with light-headedness.

What is the next most appropriate investigation for this patient?

- 1- 24hr tape
- 2- Coronary angiography
- 3- Echocardiography
- 4- Electrophysiological studies
- 5- Outpatient Cardiology referral

Answer & Comments

Answer: 3- Echocardiography

This question is a nod to the recent evidence suggesting that patients with reduced LV function and asymptomatic VT may benefit from implantation of an implantable cardiac defibrillator (eg the MADIT study). You need to know the patients cardiac function, and we feel that an ECHO would be the next most appropriate study in this patient, followed by coronary angiography and inpatient cardiology referral.

[Q: 83] OnExamination - Cardiology

A 60-year-old male with a 8 year history of type 2 diabetes is being treated with Metformin 1g bd and gliclazide 80 mg daily. He is obese, has gained weight over the last year and his HbA1c has deteriorated from 7.5 to 7.9%. His GP wishes to stop the gliclazide and treat him with Rosiglitazone. The patient wants to know the side effects of Rosiglitazone.

Which of the following would be regarded as a typical side effect of Rosiglitazone therapy?

- 1- Acanthosis nigricans
- 2- Fluid retention
- 3- Lactic acidosis
- 4- Myositis
- 5- Photosensitivity rash

Answer & Comments

Answer: 2- Fluid retention

Rosiglitazone like other PPAR gamma agonists such as Pioglitazone may cause fluid retention (about 10%) and this can be minimized by avoiding agents that may exacerbate fluid retention such as calcium antagonists. Other side effects include mild GI upset, dyspepsia, flatulence and initial weight gain (often related to fluid retention. Due to this effect, it should be avoided in patients with cardiac failure. Lactic acidosis is a recognised effect of metformin, sulphonylureas may cause a photosensitivity rash, acarbose causes GI upset and statins/fibrates are associated with myositis.

[Q: 84] OnExamination - Cardiology

A 17-year-old girl was found collapsed and drowsy. Her 12-lead ECG showed a sinus tachycardia of 120 beats per minute with a corrected QT interval of 500 ms (normal <470).

Which of the following drugs is the most likely cause of her presentation?

- 1- Amphetamine
- 2- Diphenhydramine
- 3- Glue sniffing
- 4- Methadone
- 5- Methanol

Answer & Comments

Answer: 2- Diphenhydramine

You are given here the option of choosing between two drugs that can possibly cause prolongation of QT - diphenhydramine and methadone. However, bearing in mind that she has collapsed and drowsy with a tachycardia, the most likely option is diphenhydramine as the tachycardia is more typical. Many drugs can cause a prolonged QT interval.

[Q: 85] OnExamination - Cardiology

A 19-year-old woman presents to the clinic having had 5 blackouts over the last year, all while she is standing up. She gets warnings of blurred vision, nausea, feeling hot. She had been witnessed twice to have jerking of all limbs while she is unconscious. The attacks last 30-60 seconds. She recovers quickly after the attacks. She has never bitten her tongue or sustained any injuries. Physical examination and an ECG are normal. Her grandmother and sister suffer from epilepsy.

Which of the following investigations is the most appropriate?

- 1- EEG
- 2- 24 hour ECG recording
- 3- CT brain
- 4- ECHO
- 5- Tilt table test

Answer & Comments

Answer: 5- Tilt table test

The most likely diagnosis is vasovagal syncope. The gradual onset of the attack is typical. It is common for patients with syncope to have jerking of their limbs while they are unconscious. Warning symptoms of darkening/blurring of vision, dizziness, feeling hot, is characteristic in syncope. Patients usually recover very quickly after the event. Tilt table test is a useful test to support the diagnosis of vasovagal syncope.

[Q: 86] OnExamination - Cardiology

A 66-year-old insulin dependent diabetic with a treated potassium of 5.4 mmol/l (3.5-5) and palpitations develops pulseless ventricular tachycardia. The anaesthetist is supporting Airway and Breathing.

Which of the following is the next step in his management?

- 1- Adrenaline 1mg
- 2- Amiodarone 300mg
- 3- Cardiopulmonary resuscitation 15:2 for 2 mins
- 4- Defibrillation at 150J biphasic
- 5- Praecordial thump

Answer & Comments

Answer: 4- Defibrillation at 150J biphasic

In the case of ventricular tachycardia and ventricular fibrillation immediate defibrillation is the treatment of choice. The other options come further down the algorithm and CPR is now recommended at 30:2. A praecordial thump can be administered immediately following a witnessed cardiac arrest.

[Q: 87] OnExamination - Cardiology

A 55-year-old female who had a long

history of alcohol abuse presents with diarrhoea and back pain one month after having a pacemaker inserted. On examination she had a fever of 39°C and her abdomen was soft and non-tender.

What is the most likely diagnosis?

- 1- Diverticulitis
- 2- Ischaemic colitis
- 3- Pancreatitis
- 4- Pseudomembranous colitis
- 5- Staphylococcal discitis

Answer & Comments

Answer: 5- Staphylococcal discitis

All patients with alcohol dependence have an increased risk of pancreatitis, but this is less likely without any abdominal signs. Ischaemic colitis classically presents with bloody diarrhoea. The prophylactic antibiotics given 4 weeks previously for his pacemaker insertion would not really have predisposed her to pseudomembranous colitis. Staphylococci are skin organisms most commonly introduced during pacemaker insertion and such a discitis would present with back pain.

[Q: 88] OnExamination - Cardiology

On auscultation of the heart of a 30-year-old female a loud first heart sound is heard.

Which of the following may be responsible for this auscultatory feature?

- 1- a long preceding diastolic interval
- 2- Atrial premature beat
- 3- increased pulmonary arterial pressure
- 4- increased systemic arterial pressure
- 5- rupture of a papillary muscle

Answer & Comments

Answer: 2- Atrial premature beat

A loud first heart sound is due to abrupt closure of the mitral valve against a high left atrial pressure and may occur with shortened diastole, mitral stenosis or left-right shunts. It can also be heard with atrial premature beats. MR occurs with papillary muscle rupture and thereby 1st heart sound is soft. A2 and P2 are loud in systemic HT and pulmonary hypertension respectively.

[Q: 89] OnExamination - Cardiology

A 35-year-old healthy woman has a faint systolic murmur on physical examination. An echocardiogram is performed, and she is found to have a bicuspid aortic valve.

In explaining the meaning of this finding to her, the most appropriate statement is that?

- 1- An aortic valve replacement is eventually likely to be required.
- 2- Other family members are likely to have the same condition
- 3- She should be treated with a cholesterol-lowering agent
- 4- The problem resulted from past injection drug usage
- 5- This is one manifestation of an underlying autoimmune disease process

Answer & Comments

Answer: 1- An aortic valve replacement is eventually likely to be required.

Bicuspid aortic valve is perhaps the most common form of congenital heart disease in adults (1-2% of population). Bicuspid valves have a propensity to wear out and calcify with aging. Bicuspid aortic valve tends to be a sporadic although there is a reported familial incidence of approx 9%. From a review of several sources in the literature, the Aeromedical Consultation Service (ACS) at Brooks AFB calculated a 1.2% per year incidence of aortic valve surgery in individuals

with BAV, although the vast majority occur in the 5th and 6th decades of life.

[Q: 90] OnExamination - Cardiology

A 72-year-old man presents with an episode of collapse. He has had two similar episodes recently, each lasting about one minute. Four years ago he suffered an anterior myocardial infarction.

On examination he was orientated and symptom-free with a regular pulse rate of 80 bpm, BP 140/80 mmHg and the apex beat was displaced to the left. There was an apical systolic murmur. There were no signs of trauma. ECG showed sinus rhythm, Q waves and ST segment elevation anteriorly without reciprocal depression.

What is the diagnosis?

- 1- acute anterior myocardial infarction
- 2- cerebrovascular accident
- 3- epileptic seizure
- 4- pulmonary embolism
- 5- ventricular tachycardia

Answer & Comments

Answer: 5- ventricular tachycardia

The ECG is suggestive of a left ventricular aneurysm, which has a tendency for both an malignant arrhythmogenic focus and also for left ventricular thrombus. The brief episode of loss of consciousness with no residual neurology makes the diagnosis for cerebral embolism unlikely. The story is more suggestive of a ventricular tachycardia and would suggest further investigations. Prolonged heart rhythm monitoring and an echo are recommended. If VT is proven then he should be on amiodarone and the indication for an automated implantable cardioverter/defibrillator strongly considered if the overall LV function is reduced.

[Q: 91] OnExamination - Cardiology

A 50-year-old politician presented with a strange fluttering sensation in his chest, but no chest pain. The symptoms had lasted 24 hours. An ECG revealed atrial fibrillation with a ventricular rate of 130 beats per minute.

Which one of the following drugs is most likely to restore sinus rhythm?

- 1- Adenosine
- 2- Bisoprolol
- 3- Digoxin
- 4- Flecainide
- 5- Verapamil

Answer & Comments

Answer: 4- Flecainide

Flecainide is the drug most likely to restore sinus rhythm in atrial fibrillation. Care is required in patients who may have LV dysfunction, although this is unlikely in a previously fit, relatively young patient. Adenosine is used to cardiovert supraventricular tachycardia (SVT). Digoxin and Bisoprolol are indicated for rate control and are not normally associated with the restoration of sinus rhythm. Verapamil can be used for rate control in atrial fibrillation, and may be used in the treatment of SVT.

[Q: 92] OnExamination - Cardiology

Which ONE of the following is true regarding acute pulmonary embolism?

- 1- a normal ECG excludes the diagnosis
- 2- embolectomy is more effective than thrombolysis in improving survival
- 3- Heparin is as effective as thrombolytic therapy
- 4- the presence of hypoxaemia is an indication for thrombolysis

- 5- thrombolysis administered through a peripheral vein is as effective as through a pulmonary artery catheter

Answer & Comments

Answer: 5- thrombolysis administered through a peripheral vein is as effective as through a pulmonary artery catheter

Embolectomies are rarely done nowadays due to the excellent results with thrombolysis. Thrombolytic therapy is reserved for those with severely compromised circulation (equally effective through peripheral vein or via catheter in pulmonary artery). Heparin reduces risk of further embolism (anticoagulant) and reduces pulmonary vasoconstriction.

[Q: 93] OnExamination - Cardiology

A 55-year-old male presents with dysphagia, retrosternal discomfort and weight loss. Studies reveal achalasia.

Which of the following is most likely to provide symptomatic relief?

- 1- Buscopan
- 2- Diazepam
- 3- Omeprazole
- 4- Nifedipine
- 5- Surgical cardiomyotomy

Answer & Comments

Answer: 5- Surgical cardiomyotomy

75% cure may be expected by cardiomyotomy in Achalasia. Nitrates and hydralazine can help in the short term. None of other choices help the symptoms.

Oesophageal dilatation is usually attempted before laparoscopic surgical myotomy.

[Q: 94] OnExamination - Cardiology

A 60-year-old man has a three month history of worsening dyspnoea. He has been healthy all his life with no major illnesses. His blood pressure is 118/92 mmHg, he has a murmur and has audible crackles at both bases. His serum glucose is 5.6 mmol/L. His total serum cholesterol is 4.8 mmol/L. The serum creatine kinase is not elevated.

The most likely explanation for these findings is?

- 1- Alcoholic cardiomyopathy
- 2- Aortic dissection
- 3- Calcified bicuspid aortic valve
- 4- Mitral valve annulus calcification
- 5- Tricuspid valve endocarditis

Answer & Comments

Answer: 3- Calcified bicuspid aortic valve

The clinical signs point to a left-sided heart failure which would discount alcoholic cardiomyopathy as it would be biventricular and tricuspid valve endocarditis which would be right sided. There are no acute symptoms and the history is not sudden to suggest aortic dissection. Mitral valve calcification is an incidental finding at ECHO. This leaves a calcified bicuspid aortic valve leading to aortic stenosis as the likely explanation.

[Q: 95] OnExamination - Cardiology

A 45-year-old male type 1 diabetic with a number of complex diabetic gastrointestinal complications is noted to have a PR interval of 0.18s, a QRS duration of 0.1s and a QT interval of 0.48s on routine ECG.

Which of the following drugs may be responsible?

- 1- Co-trimoxazole
- 2- Cimetidine
- 3- Domperidone

4- Erythromycin

5- Octreotide

Answer & Comments

Answer: 4- Erythromycin

Erythromycin has been associated with prolonged QT interval and torsades de pointe and is used in diabetic gastropathy although its benefits in the condition are not entirely understood. Prolonged QT is defined as greater than 0.45s. Other agents include amitriptyline and phenothiazines yet metoclopramide and domperidone are not associated.

[Q: 96] OnExamination - Cardiology

A 44-year-old man has had no major medical problems throughout his life, except for arthritis pain involving all extremities for the past couple of years. He has had worsening orthopnoea and ankle oedema in the past six months. He is afebrile. There is no chest pain. A chest X-ray shows cardiomegaly with both enlarged left and right heart borders, along with pulmonary oedema. Laboratory test findings include sodium 139 mmol/L, potassium 4.3 mmol/L, urea 7 mmol/L creatinine 95 µmol/L, and glucose 8.6 mmol/L.

Which of the following additional laboratory test findings is he most likely to have?

- 1- Anti-centromere antibody titer of 1:320
- 2- Erythrocyte sedimentation rate of 79 mm/Hr
- 3- Haemoglobin of 10.7 g/dL with MCV of 72 fL
- 4- Serum ferritin of 3400 pmol/L
- 5- Spherocytes in his peripheral blood smear

Answer & Comments

Answer: 4- Serum ferritin of 3400 pmol/L

He has findings of a cardiomyopathy with right and left heart failure. Hereditary haemochromatosis (HHC) is suspected with a serum ferritin > 1000 and confirmed by genetic testing.

Hereditary haemochromatosis is characterised by diabetes, CCF, pseudogout and slate-grey skin.

"HHC is an autosomal recessive condition and in 90% of cases in the United Kingdom (UK) the condition is owing to homozygosity for the C282Y mutation in the HFE gene. A second mutation in the HFE gene, H63D, can cause the disease when in the presence of a single C282Y mutation (the so-called 'compound heterozygote' state). These mutations are common in people of Northern European origin with a carrier frequency of the C282Y mutation of one in 10-17, in the UK, suggesting a prevalence of people homozygous for the C282Y mutation of between one in 100 and one in 280. If HHC becomes symptomatic by mid-life, a general practitioner (GP) with a list size of 2000 patients should have approximately four cases. In our experience most GPs claim to have never seen a case. Herein lies the conundrum: is HHC far more common than is currently recorded in clinical records and death registers because it is not being diagnosed, or does significant disease not develop in a large proportion of C282Y homozygotes and compound heterozygotes

[Q: 97] OnExamination - Cardiology

A 51-year-old woman has had several syncopal episodes over the past year. Each episode is characterized by sudden but brief loss of consciousness. She has no chest pain. She has no ankle edema. On brain MRI there is a 1.5 cm cystic area in the left parietal cortex. A chest X-ray shows no cardiac enlargement, and her lung fields are normal. Her serum total cholesterol is 6.5 mmol/L.

Which of the following cardiac lesions is she most likely to have?

- 1- Cardiac amyloidosis
- 2- Ischemic cardiomyopathy
- 3- Left atrial myxoma
- 4- Mitral valve prolapse
- 5- Tuberculous pericarditis

Answer & Comments

Answer: 3- Left atrial myxoma

Atrial myxomas are more often on the left. Though benign, they can occlude the mitral valve and produce sudden loss of cardiac output. They may embolize small portions of themselves or thrombus formed over their surface.

[Q: 98] OnExamination - Cardiology

A 17-year-old boy whose brother had hypertrophic cardiomyopathy was referred for a cardiological assessment. His echocardiogram confirmed the condition.

Which one of the following echocardiographic features is the most important risk factor for sudden cardiac death?

- 1- A gradient of 10 mmHg across the left ventricular outflow tract
- 2- Significant thickening of the intraventricular septum
- 3- An enlarged left atrium
- 4- Systolic anterior motion of the mitral valve
- 5- The presence of mitral regurgitation

Answer & Comments

Answer: 2- Significant thickening of the intraventricular septum

Patients die of hypertrophic obstructive cardiomyopathy by obstructing the left ventricular outflow tract (LVOT), usually during exercise. The greater the thickness of

the septum, the more likely it is to obstruct the LVOT.

[Q: 99] OnExamination - Cardiology

Which of the following concerning the use of intravenous bicarbonate in cardiorespiratory arrest is correct?

- 1- exacerbates intracellular acidosis
- 2- has a positive inotropic effect on ischaemic myocardium
- 3- improves oxygen release to the tissues
- 4- increases cerebral blood flow
- 5- reduces pre-existent hyperkalemia

Answer & Comments

Answer: 1- exacerbates intracellular acidosis

Bicarbonate therapy can increase extracellular pH only if the CO₂ produced can be removed by adequate ventilation. Indeed if hypercapnia occurs then as CO₂ crosses cell membranes easily, intracellular pH may decrease even further with further deterioration of cellular function. Has negative inotropic effect, reducing cerebral blood flow, shifts oxygen dissociation curve to the left inhibiting oxygen release to tissues.

[Q: 100] OnExamination - Cardiology

A 72-year-old man presented following three episodes of transient loss of consciousness not associated with chest pain. There was a previous history of an anterior myocardial infarction. On examination his blood pressure was 140/80 mmHg and the apex beat was diffuse in character and displaced to the left. There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

- 1- Administer tissue plasminogen activator
- 2- Arrange an electroencephalogram
- 3- Arrange immediate CT brain scan
- 4- Observe in the coronary care unit
- 5- Proceed to coronary arteriography

Answer & Comments

Answer: 4- Observe in the coronary care unit

This gentleman has persistent ST elevation, in the anterior leads, with a previous history of anterior myocardial infarction which suggests LV aneurysm. The loss of consciousness is likely to be due to recurrent arrhythmic episodes or vertebrobasilar TIAs, as a result of embolization of an LV thrombus. The most important investigation for this patient who you suspect has arrhythmic episodes would be telemetry/24 hr monitoring and hence observation on CCU is appropriate.

[Q: 101] OnExamination - Cardiology

A 68-year-old woman was admitted to hospital with severe acute dyspnoea. She denied having any chest pain but said that she had become progressively breathless over the past three months.

On examination her pulse was 120 beats per minute and regular. Her blood pressure was 95/55 mmHg and her jugular venous pressure was elevated to the angle of the jaw. Her heart sounds were normal. Auscultation of her chest revealed bilateral fine inspiratory crackles to the mid zones. She had haemorrhages in both fundi.

Investigations revealed:

Haemoglobin 5.6 g/dL (NR 11.5 - 16.5)
 Haematocrit 0.19 (NR 0.36 - 0.47)
 MCV 118 fL (NR 80 - 96)

MCH 33.0 pg (NR 28 - 32)

White cell count $3.4 \times 10^9/L$ (NR 4 - 11)

Platelets $95 \times 10^9/L$ (NR 150 - 400)

Serum Vitamin B₁₂ Result pending

Serum folate Result pending

The ECG showed left bundle branch block, which had been documented previously

She is given 80mg of intravenous furosemide which results in an excellent diuresis

What is the next most appropriate immediate step in her management?

- 1- Blood transfusion
- 2- Bone marrow aspiration
- 3- Start intramuscular Vitamin B₁₂ and oral folic acid
- 4- Start oral ferrous sulphate
- 5- Thrombolyse with t-PA

Answer & Comments

Answer: 1- Blood transfusion

The clinical picture represents severe megaloblastic anaemia with cardiac failure.

The questions asks about immediate management. Although the anaemia has been developing slowly, she has become acutely haemodynamically compromised. In such circumstances it would be most appropriate to transfuse the patient. This would need to be done very cautiously with diuretic cover.

She will clearly need to start an intensive course of intramuscular vitamin B₁₂ and oral folic acid as well, but this is less important in the hyperacute situation where there is a risk of the patient dying from anaemia.

Giving oral folic acid without vitamin B₁₂ would be hazardous and could precipitate subacute combined degeneration of the spinal cord. Transfusion may also be hazardous in a patient with severe CCF

[Q: 102] OnExamination -
Cardiology

A 57-year-old male is admitted with acute dyspnoea and chest pain. A PE is confirmed.

Which of the following is a recognised feature of a significant pulmonary embolism?

- 1- reduced plasma lactate levels
- 2- an increase in serum troponin levels
- 3- an arterial pH less than 7.2
- 4- blood gases show increased pCO₂ on air
- 5- normal D-dimer levels

Answer & Comments

Answer: 2- an increase in serum troponin levels

Cardiac troponins are reliable markers of myocardial injury that are being used increasingly in patients presenting with undifferentiated chest pain or dyspnea to diagnose an acute coronary syndrome. If elevated cardiac troponin levels also occur in patients with pulmonary embolism because of right ventricular dilation and myocardial injury, such patients could be misdiagnosed. We performed a prospective cohort study to determine the prevalence of elevated cardiac troponin I (cTnI) levels in patients with submassive pulmonary embolism. METHODS: Consecutive patients with objectively confirmed submassive pulmonary embolism and no previous history of ischemic heart disease, other cardiac disease, or renal insufficiency were included. Creatine kinase and cTnI levels were measured within 24 hours of clinical presentation on 2 occasions 8 to 12 hours apart. RESULTS: Of 24 patients with submassive pulmonary embolism, 5 (20.8%) had elevated cTnI levels of 0.4 microg/L or higher (95% confidence interval, 7.1-42.2%). One of these patients had a cTnI level higher than 2.3 microg/L that was suggestive of myocardial infarction. CONCLUSION: Pulmonary embolism should be

considered in the differential diagnosis of patients presenting with undifferentiated chest pain or dyspnea and an elevated cardiac troponin level. (Arch Intern Med, 162(1): 79-81 2002)

Hypoxemia and hypocapnoea are common after major pulmonary embolism and may also be found after more minor events. Absence of these phenomena, on the other hand, by no means excludes embolism and their presence is non-specific. In suspected minor embolism this investigation is, at best, only of marginal value. The precise stimulus to hyperventilation is unknown and there is also difficulty in understanding the reasons for hypoxaemia when it is present.

[Q: 103] OnExamination -
Cardiology

A 14-year-old boy presents with fever.

Which of the following might contribute to a diagnosis of rheumatic fever?

- 1- The finding of target lesions on the hands.
- 2- The finding of tender nodules in the fingertips.
- 3- A prolonged PR interval on ECG.
- 4- A CRP of 10.
- 5- Positive Romberg's sign.

Answer & Comments

Answer: 3- A prolonged PR interval on ECG.

The modified Jones Criteria include: Finding of preceeding streptococcal infection (recent scarlett fever, raised ASOT or other streptococcal antibodies, positive throat swab for Group A Strep). Plus:

a) MAJOR CRITERIA:

- o Carditis
- o Polyarthritis
- o Chorea

- o Subcutaneous nodules
- o Erythema marginatum.

b) MINOR CRITERIA:

- o Fever
- o Arthralgia
- o Previous history of rheumatic fever
- o Elevated acute phase reactions
- o Prolonged PR interval.

Erythema marginatum involves red circular lesions which gradually enlarge with central clearing. Sydenham's chorea consists of choreoathetoid movements with increased clumsiness, e.g. deteriorating handwriting. This is often associated with emotional lability. Target lesions suggest erythema multiforme. A CRP of 10 is not elevated much beyond the normal range. Erythema marginatum initially manifests as non-specific pink macules seen over the trunk, with later blanching in the middle of the lesions and sometimes fusing of the borders resulting in a serpiginous (serpent-like) looking lesion. The rash is worsened with heat, but is characteristically evanescent. It does not itch, and can be mistaken for the rash of Lyme disease. Sub-cutaneous nodules are pea-sized, firm and non-tender. There is no associated inflammation and they are characteristically seen on the extensor surfaces of joints such as knees and elbows and also over the spine.

[Q: 104] OnExamination - Cardiology

A 66-year-old insulin dependent diabetic given ibuprofen for a knee injury is admitted with palpitations. His electrocardiogram shows a rate of 105 beats per min, with absent P waves and tall T waves. His Urea and Electrolytes show:

Sodium	132 mmol/l	(133-144)
Potassium	6.4 mmol/l	(3.5-5)

Urea	11 mmol/l	(3-8)
------	-----------	-------

Creatinine	180 micromol/l	(50-100)
------------	----------------	----------

In this scenario, which of the following is the most appropriate immediate management?

- 1- Calcium Chloride 10mmol IV
- 2- Calcium Resonium orally
- 3- Dextrose 50mls 50% with 10 units insulin
- 4- Dialysis
- 5- Furosemide 1mg/kg IV

Answer & Comments

Answer: 1- Calcium Chloride 10mmol IV

The ECG suggests cardiotoxicity related to hyperkalaemia and the history of palpitations is suggestive of arrhythmias. Therefore cardio protection with Calcium Chloride or gluconate should be first priority and lowering potassium levels immediately thereafter.

[Q: 105] OnExamination - Cardiology

A 16-year-old boy is admitted after a blackout at the dentist. His mother describes how he blacked out as the dentists began performing a filling and that he jerked his arms a few times and was then incontinent. He awoke after a minute or so and was oriented but nauseous. There were no similar episodes in the past and he is totally unaware of what happened.

Examination was normal and his ECG was normal.

Which one of the following is the most likely diagnosis?

- 1- Complex partial seizure
- 2- Pseudoseizure
- 3- Stokes-Adams attack
- 4- Tonic-clonic seizure
- 5- Vasovagal syncope

Answer & Comments

Answer: 5- Vasovagal syncope

Vasovagal syncope is common during dental procedures, mainly induced by pain (as the dentist started drilling). The fact that he recovered very quickly supports the diagnosis of syncope. It is common to have jerking of limbs due to brain hypoxia. ECG is always normal. Incontinence of urine can occur but not biting of the tongue.

[Q: 106] OnExamination -
Cardiology

A 58-year-old male presents with acute dyspnoea following a convulsion. On examination his blood pressure was 240/120 mmHg and fundal examination reveals pailloedema with haemorrhages and cotton wool spots. His urea, electrolytes and creatinine are normal but chest X-ray reveals pulmonary oedema and cardiomegaly.

Which one of the following is the most appropriate immediate treatment?

- 1- atenolol 50 mg orally
- 2- intravenous labetalol
- 3- intravenous sodium nitroprusside
- 4- nifedipine 5 mg sublingually
- 5- nifedipine LA 30 mg orally

Answer & Comments

Answer: 3- intravenous sodium nitroprusside

This patient has malignant hypertension with papilloedema, convulsions and pulmonary oedema (thus excluding the use of a β -blocker in the acute setting). This constitutes a medical emergency with Nitroprusside being the treatment of choice.

[Q: 107] OnExamination -
Cardiology

A 59-year-old man is admitted with chest pain

of 8 hours duration and has ST elevation in the inferior leads on his admission ECG. An electrocardiogram from a previous clinic visit shows sinus rhythm two months ago. He has insulin dependent diabetes mellitus and chronic renal failure.

Investigations reveal:

Fasting plasma glucose 7.4 mmol/l (3.5-6)

Sodium 137 mmol/l (134-144)

Potassium 4.4 mmol/l (3.5-5)>

Urea 10 mmol/l (3-8)

Creatinine 200 micromol/l (50-100)

Which of the following which represent an absolute contraindication to the use of thrombolysis?

- 1- Allergy to penicillin.
- 2- Gastro intestinal bleeding in last 3 months.
- 3- History of haemorrhagic stroke.
- 4- Ischaemic stroke 12 months ago
- 5- On warfarin therapy

Answer & Comments

Answer: 3- History of haemorrhagic stroke.

Absolute contraindications to thrombolysis include:

Previous haemorrhagic stroke

Ischaemic stroke in last 6 months

Central nervous system damage or neoplasm

Within 3 weeks of major surgery, head injury or major trauma

Active internal bleeding (menses excluded) or gastro-intestinal bleeding within the past month.

Known or suspected aortic dissection

Known bleeding disorder

Proliferative diabetic retinopathy

Allergy and oral anticoagulants are relative contraindications.

[Q: 108] OnExamination -
Cardiology

Which one of the following is the most likely mechanism by which Aspirin exerts its beneficial effects in patients with coronary artery disease?

- 1- anti-inflammatory action
- 2- cyclo-oxygenase inhibition
- 3- glycoprotein IIB/IIIA receptor inhibition
- 4- inhibition of binding of adenosine diphosphate to its platelet receptor
- 5- structural changes in platelets

Answer & Comments

Answer: 2- cyclo-oxygenase inhibition

It inhibits platelet aggregation through inhibition on both COX I and II. Clopidogrel inhibits ADP binding to platelet receptors.

[Q: 109] OnExamination -
Cardiology

A 65-year-old male attends clinic complaining of breathlessness. He has endstage cardiac failure due to dilated cardiomyopathy. Currently he takes Furosemide, Lisinopril and Cardvedilol.

Which one of the following drugs should be added to his current therapy?

- 1- Diltiazem
- 2- Digoxin
- 3- Isosorbide Mononitrate
- 4- Nicorandil
- 5- Vitamin C

Answer & Comments

Answer: 2- Digoxin

Digoxin has a positive inotropic effect, it can be used in patients with heart failure who are in sinus rhythm but remain symptomatic despite therapy with an ACE inhibitor diuretic and beta blocker.

[Q: 110] OnExamination -
Cardiology

A 52-year-old male presents with a 3 week history of fevers, deteriorating breathlessness and fatigue. Two years ago he underwent prosthetic valve replacement for a calcified bicuspid aortic valve. On examination he has a temperature of 37.7°C and four nailfold infarcts. Vegetations are demonstrated through trans-oesophageal echocardiography.

Which of the following is the most likely causative organism?

- 1- Candida spp.
- 2- Enterococcus
- 3- Staphylococcus aureus
- 4- Staphylococcus epidermidis
- 5- Streptococcus viridans

Answer & Comments

Answer: 5- Streptococcus viridans

Generally there are two identifiable modes of prosthetic valve endocarditis. The first occurs within the first year after surgery affecting 0.7-3% of cases and is often due to staphylococci. Late endocarditis observed after two years post surgery is found in 0.5-1% of cases and is typically due to streptococci - typically group A haemolytic otherwise known as strep viridans.

[Q: 111] OnExamination -
Cardiology

A 35-year-old woman presented with a history of intermittent light-headedness. Clinical examination and 12-lead ECG were normal.

Which of the following, if present on a 24 hour Holter ECG tracing, would be the most clinically important?

- 1- Atrial premature beats.
- 2- Profound sleep-associated bradycardia.
- 3- Supraventricular tachycardia.
- 4- Transient Mobitz type 1 atrioventricular block.
- 5- Ventricular premature beats.

Answer & Comments

Answer: 3- Supraventricular tachycardia.

SVT commonly presents with palpitations but occasionally is associated with light-headedness. I really struggled with this question. I think it is what examiners refer to as a discriminatory question or basically one with no right answer. The problem is that intuitively SVT is the most common arrhythmia in this age group and can be associated with light-headedness but as you know significant SVT commonly presents with palpitations; however, There is no mention of palpitations. The word "profound", preceding sleep-associated bradycardia is confusing; are they alluding to the fact that this woman has sick sinus and significant bradycardia has only manifested itself in her sleep? Is this more than just normal sleep associated bradycardia? I don't think that is the right answer though. Then there is D, Wenkebach is almost always asymptomatic but what is a 35-year-old doing with Mobitz type I (it is commonly seen in athletes - Dean Jenkins)? We had a straw poll here at cardiology and decided in the end the right answer is C, which I agree with.

[Q: 112] OnExamination - Cardiology

A 65-year-old African man with a known history of hypertension presents with ankle oedema after taking an antihypertensive

prescribed by his General Practitioner. He is now found to have a Blood Pressure of 160/100 mmHg.

Which of the following would be the preferred drug for this patient?

- 1- Amlodipine
- 2- Atenolol
- 3- Bendroflumethiazide
- 4- Ramipril
- 5- Verapamil

Answer & Comments

Answer: 3- Bendroflumethiazide

The patient has ankle oedema which is usually due to vasodilatation by calcium channel blockers. The preferred initial antihypertensive therapy for the elderly African patient will be bendroflumethiazide according to BHS guideline, 2004. ACE inhibitors are preferred for those patients with heart failure or Diabetic nephropathy. β -Blockers are preferred for post-myocardial infarction and ischemic heart disease.

[Q: 113] OnExamination - Cardiology

A 30-year-old man presents with a history of transient loss of consciousness and palpitations. His ECG shows ventricular tachycardia.

Which of the following treatments should be avoided?

- 1- adenosine
- 2- amiodarone
- 3- DC cardioversion
- 4- flecainide
- 5- verapamil

Answer & Comments

Answer: 5- verapamil

If there were 'killer' questions (questions that if a candidate got wrong they would certainly fail the exam) in the MRCP exam then this would be one of them. Verapamil should be avoided in cases of VT because it can cause a catastrophic fall in blood pressure. Adenosine is useful diagnostically when the diagnosis of regular wide complex tachycardia is in doubt. Amiodarone is a useful antiarrhythmic agent though its use acutely is limited by its irritant nature on veins. DC Cardioversion is probably the treatment of choice in this case. Flecainide is a good antiarrhythmic and would be indicated in patients without LV failure (it is associated with an increased risk of death in such cases). Flecainide is widely used for atrial fibrillation.

[Q: 114] OnExamination - Cardiology

A 45-year-old female presents with a two day history of fever and joint pains. She has a past history of hypertension for which she is receiving anti-hypertensives. On examination she has a temperature of 38°C, a facial rash and slight swelling with tenderness of the wrist and ankle joints.

Which of the following anti-hypertensives is most likely to be responsible for her presentation?

- 1- Alpha-methyldopa
- 2- Bendroflumethiazide
- 3- Hydralazine
- 4- Minoxidil
- 5- Phenoxybenzamine

Answer & Comments

Answer: 3- Hydralazine

The presence of fever, facial rash and arthralgia suggest a diagnosis of drug-induced SLE, with hydralazine being a well recognised cause. Gout may be precipitated by bendroflumethiazide and it also causes a

photosensitivity rash but the two diagnoses together with a fever would be remote.

[Q: 115] OnExamination - Cardiology

A 34-year-old male presents with episodes of breathlessness on exertion. Examination reveals a loud P2 and fixed splitting of the second sound.

Which of the following may be responsible for these signs?

- 1- Excess maternal alcohol consumption
- 2- Homocystinuria
- 3- 47 XXY karyotype
- 4- Maternal chicken pox infection
- 5- Maternal thalidomide therapy

Answer & Comments

Answer: 1- Excess maternal alcohol consumption

Fetal alcohol syndrome, Down's syndrome and Congenital rubella syndrome are associated with an ASD as described in this case with a loud second sound plus fixed splitting.

[Q: 116] OnExamination - Cardiology

A 70-year-old man is admitted with an acute Q-wave inferior Myocardial Infarction. On day 5, he suddenly develops pulmonary oedema and a loud systolic murmur.

Which of the following would be the most useful in establishing a diagnosis?

- 1- chest X-ray
- 2- coronary arteriography
- 3- ECG
- 4- right heart catheterisation and oximetry
- 5- serum cardiac enzymes

Answer & Comments

Answer: 4- right heart catheterisation and oximetry

This patient has developed acute LVF 5 days after an inferior MI. Things to think about include MV prolapse, VSD or acute pericardial effusion/haemorrhage. Right heart studies would provide information on LA pressures and suggestive information on the most likely diagnosis - MV prolapse.

[Q: 117] OnExamination - Cardiology

A 40-year-old male attends for a consultation after discovering that his brother has been diagnosed with a familial hypertrophic obstructive cardiomyopathy.

Which screening method should he be offered?

- 1- Coronary Angiograms
- 2- Exercise ECG
- 3- Genetic testing
- 4- Transthoracic Echocardiogram
- 5- Transoesophageal Echocardiogram

Answer & Comments

Answer: 4- Transthoracic Echocardiogram

Current guidelines suggest that a resting ECG and TTE (transthoracic ECHO) are the most effective screening strategy for relatives of patients with HOCM. Genetic testing is not recommended as a first line screening tool given varying rates of penetrance.

[Q: 118] OnExamination - Cardiology

A 58 year-old male is admitted with a blood pressure of 210/120 and episodic runs of ventricular tachycardia. Investigations confirm the presence of a right adrenal pheochromocytoma.

Which one of the following would be the most appropriate initial therapy?

- 1- Amiodarone
- 2- Atenolol
- 3- Lidocaine
- 4- Phenoxybenzamine
- 5- Propofenone

Answer & Comments

Answer: 4- Phenoxybenzamine

This patient has catecholamine-induced severe hypertension and associated paroxysmal ventricular tachycardia. The patient should initially be alpha-blocked with phenoxybenzamine and then β -blockers introduced. This should control the runs of VT but for sustained VT lidocaine can be acutely used.

[Q: 119] OnExamination - Cardiology

Which of the following statements are true of coronary artery anatomy?

- 1- Right bundle branch block in acute anterior myocardial infarction suggests obstruction prior to the first septal branch of the left anterior descending coronary artery
- 2- the posterior descending artery is usually a branch of the circumflex artery
- 3- The sinus node is supplied by a branch of the right coronary in over 90% of subjects.
- 4- The AV node is supplied by the left anterior descending coronary artery.
- 5- The left main stem is about 4 cm long

Answer & Comments

Answer: 1- Right bundle branch block in acute anterior myocardial infarction suggests obstruction prior to the first septal branch of the left anterior descending coronary artery

It is sometimes said that questions longer than 2 lines are usually false ... but not in this case.

The posterior descending artery is most often (85%) a branch of the right coronary artery. The sinus node artery is a branch of the right coronary artery in 60% of cases. The AV node is supplied from the posterior descending coronary artery. The left main stem is much shorter than 4 cm!

[Q: 120] OnExamination - Cardiology

Left axis deviation is seen on the ECG in which of the following conditions?

- 1- atrioventricular canal defects.
- 2- Ebstein's anomaly.
- 3- large ventricular septal defect.
- 4- patent ductus arteriosus.
- 5- tetralogy of Fallot.

Answer & Comments

Answer: 1- atrioventricular canal defects.

Left axis deviation is also seen in tricuspid atresia.

[Q: 121] OnExamination - Cardiology

A 72-year-old man is admitted with fast atrial fibrillation but is receiving treatment with digoxin. An inadequate dose is suspected. A sample of blood is drawn six hours after the last dose of digoxin and a plasma concentration is requested.

Which of the following factors explains the six hour wait before measuring the digoxin concentration?

- 1- enterohepatic circulation
- 2- the rate of absorption
- 3- the rate of clearance
- 4- the rate of distribution

- 5- the rate of elimination

Answer & Comments

Answer: 4- the rate of distribution

A blood sample needs to be drawn at least six hours after administration of digoxin to ensure adequate distribution.

[Q: 122] OnExamination - Cardiology

A 26-year-old man is noted to have cyanosis of the lower limbs and clubbing of the toes but not the fingers.

Which of the following statements is true?

- 1- He has Eisenmenger's syndrome.
- 2- He has coarctation of the aorta.
- 3- He is likely to have a loud continuous 'machinery' murmur below the left clavicle.
- 4- He is likely to need urgent surgery.
- 5- He has had a Blalock shunt operation.

Answer & Comments

Answer: 1- He has Eisenmenger's syndrome.

This is the differential cyanosis of a reversed patent ductus arteriosus (PDA). There is a right-left shunt from the pulmonary artery to the aorta just distal to the left subclavian artery.

Coarctation causes radiofemoral delay. It may be associated with PDA but there is no suggestion in this patient.

Continuous machinery murmur is the classic murmur of PDA but when the shunt reverses (as in patients with a large PDA and/or pulmonary disease) the murmur becomes softer and shorter.

When Eisenmenger's syndrome has developed surgery is associated with a very high mortality.

A Blalock shunt (anastomosis of subclavian artery to pulmonary artery) used to be performed for Fallot's tetralogy and leads to a weak left radial pulse.

[Q: 123] OnExamination - Cardiology

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention of ischaemic heart disease in a diabetic population. 1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period. In the placebo group there were 150 myocardial infarcts and in the group treated with the new statin there were 100 myocardial infarcts.

What is the number needed to treat to prevent one MI over the course of this study?

- 1- 10
- 2- 20
- 3- 30
- 4- 40
- 5- 50

Answer & Comments

Answer: 2- 20

You treat 1000 patients for 5 years with the new statin and prevent 50 MIs. Thus the Number Needed to Treat (NNT) to prevent 1 MI is 20 (1000/50). Again, this statistical figure provides us with a lot of information regarding the efficacy of a treatment rather than purely statistically significant data. As it stands, you may expect to prevent an infarct by treating as few as 20 patients over 5 years from this data. Furthermore, cost economic data can be calculated from such results by factoring in how much the drug costs against all the costs of treating and rehabilitating a patient with an MI.

[Q: 124] OnExamination - Cardiology

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention of ischaemic heart disease in a diabetic population. 1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period. In the placebo group there were 150 Myocardial infarcts and in the group treated with the new statin there were 100 infarcts.

What is the relative risk reduction of MI afforded by statin therapy?

- 1- 15%
- 2- 25%
- 3- 33%
- 4- 40%
- 5- 50%

Answer & Comments

Answer: 3- 33%

There are 50 fewer MIs in the treated group than the placebo treated group, hence $50/150=33\%$. The relative risk reduction provides information regarding the efficacy of a therapy and what reduction in risk may be expected when treating subjects rather than just having data relating to the significance of the data.

[Q: 125] OnExamination - Cardiology

A 62-year-old man has experienced substernal chest pain upon exertion with increasing frequency over the past 1 year. An electrocardiogram shows T wave inversion in the anterolateral leads at rest. He has a total serum cholesterol of 7.0 mmol/l. On angiography, he has an 85% narrowing of the left anterior descending artery.

Which of the following events is most likely to occur in this patient?

- 1- A systemic artery embolus from thrombosis in a peripheral vein.
- 2- A systemic artery embolus from a left atrial mural thrombus.
- 3- Pulmonary embolism from a left ventricular mural thrombus
- 4- A systemic artery embolus from a left ventricular mural thrombus.
- 5- Pulmonary embolism from thrombosis in a peripheral vein.

Answer & Comments

Answer: 4- A systemic artery embolus from a left ventricular mural thrombus.

The suggestion here is that this man has coronary artery disease with an impending myocardial infarction. Infarction of the LAD would cause necrosis of the left ventricle. Thrombus may form on an area of dyskinetic ventricle. Therefore he is most at risk of embolus of thrombus from the LV.

[Q: 126] OnExamination - Cardiology

In a trial of a new drug the following results were obtained:

	improved	not improved
treatment group	44	16
placebo group	36	26

Which of the following statements regarding the statistical analysis or interpretation of the trial is true?

- 1- A Student t-test could be used.
- 2- Pearson's coefficient of linear regression would be an appropriate significance test.
- 3- The data could be evaluated using the Chi-squared test.
- 4- The numbers are too small to draw any conclusions.

- 5- The results so obviously show the benefit of treatment that statistical analysis is not required.

Answer & Comments

Answer: 3- The data could be evaluated using the Chi-squared test.

This data would be ideal for a Chi-squared test. It is a 2 x 2 contingency table for which there is a special Chi-squared formula that gives a value that can be looked up in a table giving the p value.

Nothing is ever so obvious that no statistical analysis is needed surely? Pearson's coefficient cannot be calculated as there is no linear regression to plot. The Student t-test cannot be used as we are comparing proportions not means.

[Q: 127] OnExamination - Cardiology

With regard to cardiac troponins, which ONE of the following statements is correct?

- 1- Elevated plasma troponin concentrations are specific markers of ischaemic heart disease
- 2- Plasma troponin concentrations are typically elevated three weeks after an acute myocardial infarction
- 3- Plasma troponin concentrations are typically reduced in subjects with atrial fibrillation
- 4- The specificity of troponins for myocardial injury is similar to that of creatine kinase-MB
- 5- The clinical role of troponins is to rule out acute myocardial infarction in patients presenting with chest pain

Answer & Comments

Answer: 5- The clinical role of troponins is to rule out acute myocardial infarction in patients presenting with chest pain

Elevated troponin concentrations are highly specific for cardiac injury/infarction and are usually normal in patients with ischaemic heart disease/angina but may also be elevated in patients with pulmonary embolism or renal failure (reduced excretion). Concentrations typically peak 12-24 hrs after myocardial injury and remain elevated for 7-14 days. Studies reveal that raised troponins are far more specific than CK-MB.

[Q: 128] OnExamination - Cardiology

A 64-year-old man is admitted with a right femoral neck fracture following a fall. Also seen in the radiograph of the pelvis are several prominent calcified vessels.

What is the most appropriate next step in management of this finding?

- 1- Anticoagulate with heparin
- 2- Ignore it
- 3- Order a pulmonary ventilation-perfusion scan
- 4- Request a serum troponin test
- 5- Start the patient on a nitrate infusion

Answer & Comments

Answer: 2- Ignore it

This finding is typical for Monckeberg's calcific medial sclerosis, a benign condition involving muscular arteries of older persons.

[Q: 129] OnExamination - Cardiology

Whilst attending the cardiology clinic, the staff nurse measures the blood pressure of a 61-year-old man, and finds that it is 183/100

mmHg sitting and 190/105 standing. He has a heart rate of 81/minute, with an irregularly irregular rhythm. On auscultation of the heart, there are no murmurs, but he has bibasilar crackles on chest examination.

Which of the following pathological findings is most likely to be present?

- 1- Left ventricular hypertrophy
- 2- Left atrial myxoma
- 3- Occlusive coronary atherosclerosis
- 4- Cor pulmonale
- 5- Mitral regurgitation

Answer & Comments

Answer: 1- Left ventricular hypertrophy

This gentleman is likely to have a hypertensive cardiomyopathy with a left ventricle hypertrophy. The LVH is secondary to increased afterload, as a result of chronic hypertension. The AF, suggested by an irregularly irregular pulse is an indicator of diastolic dysfunction and poor ventricular filling. This in turn the pulmonary congestion, as evidenced by the bibasal crackles. There is no murmur or plop to suggest atrial myxoma.

[Q: 130] OnExamination - Cardiology

Which of the following lipid abnormalities are most likely to be detected in a diabetic patient?

- 1- Elevated HDL concentrations
- 2- Elevated LDL concentrations
- 3- Large buoyant LDL molecules
- 4- Reduced triglycerides concentrations
- 5- Small dense LDL molecules

Answer & Comments

Answer: 5- Small dense LDL molecules

In type 2 diabetes increased CETP activity results in the transfer of triglycerides from VLDL to HDL and LDL. This results in small dense LDL which is more atherogenic being able to be oxidised more readily and penetrate endothelium and macrophages. LDL is not typically elevated in type 2 diabetes, although there are qualitative changes as indicated above. HDL is typically low in the type 2 diabetic patient.

[Q: 131] OnExamination - Cardiology

A 72-year-old man noted to have a systolic murmur undergoes an echocardiogram which demonstrates aortic stenosis.

Which of the following is associated with a poor prognosis in this patient?

- 1- Aortic regurgitation
- 2- Cardiomegaly on chest X-ray
- 3- Clinical features of left ventricular failure
- 4- ECG evidence of left ventricular hypertrophy
- 5- severe valvular calcification on echocardiogram

Answer & Comments

Answer: 3- Clinical features of left ventricular failure

Aortic stenosis is associated with a worse prognosis when accompanied by left ventricular dysfunction. Other predictors of a poorer prognosis include increasing gradient across the valve (above 70 mmHg), age of patient and symptomatology. Although the severity of valvular calcification is prognostically important in an asymptomatic patient the most important predictor is LV function.

[Q: 132] OnExamination - Cardiology

A 68 year-old woman with atrial fibrillation is admitted for DC cardioversion. The procedure resulted in successful restoration of sinus rhythm.

Which one of the following drugs would be most likely to maintain sinus rhythm following this procedure?

- 1- amiodarone
- 2- digoxin
- 3- diltiazem
- 4- sotalol
- 5- verapamil

Answer & Comments

Answer: 1- amiodarone

Amiodarone has been shown to be superior in maintaining sinus rhythm following "DC cardioversion" of AF. However, it is associated with more toxic side effects than the other agents mentioned. Neither verapamil, diltiazem nor digoxin would be expected to maintain sinus rhythm to any significant extent. Sotalol may be considered as a possible therapy but is less effective than amiodarone.

[Q: 133] OnExamination - Cardiology

A 25-year-old previously healthy woman has worsening fatigue with dyspnoea, palpitations, and fever over the past one week. Her vital signs on admission to the hospital show Temperature 38.9°C Respiratory rate 30/min Pulse 105 bpm and BP 95/65 mmHg. Her heart rate is irregular. An ECG shows diffuse ST-T segment changes. A Chest X-ray shows mild cardiomegaly. An echocardiogram shows slight mitral and tricuspid regurgitation but no valvular vegetations. Her troponin I is 12 ng/mL

(NR<0.04). She recovers over the next two weeks with no apparent sequelae.

Which of the following laboratory test findings best explains the underlying etiology for these events?

- 1- ANCA titer of 1:80
- 2- Anti-streptolysin O titer of 1:512
- 3- Blood culture positive for Streptococcus, viridans group
- 4- Coxsackie B serologic titer of 1:160
- 5- Total serum cholesterol of 9.6 mmol/l

Answer & Comments

Answer: 4- Coxsackie B serologic titer of 1:160

She has findings that suggest myocarditis, and is supported by the temperature, echo findings and markedly raised troponin. Myocarditis can have features similar to cardiomyopathy and the mild valvular disease is quite compatible. One of the most likely organisms is Coxsackie B virus.

[Q: 134] OnExamination - Cardiology

An 80 year-old male presented with palpitations of 5 hours duration. One month previously he suffered weakness of the right arm and problems with his speech which resolved within 4 hours. He was taking no medication. On examination, he was stable with a pulse of 135 beats per minute which was confirmed to be atrial fibrillation on ECG. He had a blood pressure of 112/80 mmHg, appeared clinically euthyroid. Within one hour he reverted to sinus rhythm spontaneously. Echocardiogram was normal but a 24 hour ECG revealed three episodes of atrial fibrillation each lasting around ten minutes.

Which one of the following is the most appropriate initial treatment for this patient?

- 1- Amiodarone
- 2- Aspirin

- 3- atenolol
- 4- digoxin
- 5- warfarin

Answer & Comments

Answer: 5- warfarin

The most appropriate initial therapy for this patient who has a high risk of thrombo-embolic stroke is anticoagulation with warfarin maintaining an INR between 2-2.5. This should be the initial priority as he has already had one episode of TIA. The maintenance of sinus rhythm would be the next step and amiodarone or sotalol are options.

[Q: 135] OnExamination - Cardiology

A 70-year-old man with dilated cardiomyopathy remains symptomatic in NYHA class 2 due to chronic heart failure. On examination his pulse is 90 regular, BP 140/90, heart sounds normal, chest auscultation did not reveal any abnormalities. He is currently taking Lisinopril 30 mg OD and Furosemide 80 mg OD.

What is the best treatment option?

- 1- Amiodarone
- 2- Carvedilol
- 3- Digoxin
- 4- Spironolactone
- 5- Valsartan

Answer & Comments

Answer: 2- Carvedilol

Beta blockers improve mortality and quality of life in chronic heart failure (COPERNICUS, MERIT, CIBIS trials). They should be initiated once patients are stable and can be used in all classes of heart failure though they can cause an acute deterioration in patients who have

very severe symptoms. They should be avoided in the acute setting. Spironolactone improves outcome and symptoms in severe (Class 3-4) chronic heart failure (RALES). Valsartan does not affect outcome as add on treatment (VALHEFT). Digoxin may reduce hospitalisation and improves QOL but has a neutral benefit to mortality (DIG study). Amiodarone in the absence of arrhythmias does not affect outcome.

[Q: 136] OnExamination - Cardiology

A previously well 60-year-old lady is admitted with an Acute Anterior Myocardial Infarction. A random blood glucose concentration was found to be 12.1 mmol/L (<6.7).

What is the optimal management of her blood sugar?

- 1- Diet
- 2- Gliclazide
- 3- Intravenous insulin plus dextrose
- 4- Metformin
- 5- Subcutaneous insulin

Answer & Comments

Answer: 3- Intravenous insulin plus dextrose

The DIGAMI study has demonstrated that there is a survival advantage in initially treating such patients with elevated glucose concentrations with sliding scale insulin for 24 hours post-infarct and then switching to three months subcutaneous insulin. (Almbrand B, Johannesson M, Sjostrand B, Malmberg K, Ryden L. Cost Effectiveness of Intense Insulin Treatment after Acute Myocardial Infarction in Patients with Diabetes Mellitus.

Results from the DIGAMI study Eur Heart J 2000; 21: 733-39)

[Q: 137] OnExamination - Cardiology

Which of the following regarding the anatomy of the heart is true?

- 1- The aortic valve is tricuspid.
- 2- The ascending aorta is entirely outside the pericardial sac.
- 3- The left atrial appendage is identified readily by transthoracic echocardiography.
- 4- The pulmonary trunk lies anterior to the ascending aorta.
- 5- The right atrium is posterior to the left atrium.

Answer & Comments

Answer: 1- The aortic valve is tricuspid.

The pulmonary trunk lies posterior to the aorta. The ascending aorta lies completely within the pericardium as does the pulmonary trunk. The left atrium is the most posterior chamber of the heart, the right atrium is just anterior and to the right of the left atrium. The left atrial appendage is not readily seen on transthoracic echocardiography and requires transoesophageal echocardiography.

[Q: 138] OnExamination - Cardiology

A 41 year male on routine risk factor screening is noted to have a blood pressure of 146/86 mm/Hg.

His investigations reveal:

Fasting plasma glucose 5.8 mmol/l 3.5-6
 Total cholesterol 6.2 mmol/l <5.2
 Triglyceride 12.8 mmol/l 0.5-1.7
 HDL-Cholesterol 0.8 mmol/l 0.7-1.7

Which is the most appropriate treatment for his lipid profile?

- 1- Ezetimibe
- 2- Fenofibrate

- 3- Nicotinic acid slow release
- 4- Rosuvastatin
- 5- Simvastatin

Answer & Comments

Answer: 3- Nicotinic acid slow release

This patient is likely to have type V hyperlipoproteinaemia characterised by an excess of triglyceride containing lipoproteins and an increased risk of pancreatitis. Nicotinic acid primarily reduces plasma TG levels via inhibition of hepatic TG synthesis suppressing FFA supply to the liver. It is currently the most effective TG reducing pharmacotherapy producing reductions of up to 30% in plasma TG at a dose of 2 g a day. Its use is limited by side effects mainly flushing and an exacerbation of insulin resistance. The flushing may be diminished by gradual dose escalation, consumption following a low fat snack and concomitant aspirin use. Alternative therapies in the event of intolerance to nicotinic acid include fenofibrate as a good second choice or alternatively, Omega-3 fatty acids.

[Q: 139] OnExamination - Cardiology

A 70-year-old male with a history of syncope and hypertension is found to have runs of non-sustained ventricular tachycardia during telemetry.

Investigations show a serum magnesium of 0.4 mmol/l (0.75-1).

Which one of the following is most likely to be responsible for this biochemical abnormality?

- 1- Chronic renal failure
- 2- Diuretic therapy
- 3- Elevated PTH concentrations
- 4- Hyperphosphataemia
- 5- Treatment with antacids

Answer & Comments

Answer: 2- Diuretic therapy

Diuretic therapy is a common cause of hypomagnesaemia due to increased renal excretion. It is not seen in hyperparathyroidism. Chronic renal failure and antacid therapy are both causes of hypermagnesaemia. Hypophosphatemia is seen in association with hypomagnesaemia.

[Q: 140] OnExamination - Cardiology

Cyanosis is a typical feature of which of the following conditions:

- 1- Patent ductus arteriosus.
- 2- Ventricular septal defect.
- 3- Total anomalous pulmonary venous drainage.
- 4- Atrial septal defect
- 5- Mitral atresia.

Answer & Comments

Answer: 3- Total anomalous pulmonary venous drainage.

TAPVD is associated with cyanosis in the newborn. Total anomalous pulmonary venous connection (TAPVC) consists of an abnormality of blood flow in which all 4 pulmonary veins drain into systemic veins or the right atrium with or without pulmonary venous obstruction. Systemic and pulmonary venous blood mix in the right atrium. PDA, ASD and VSD are left to right shunts. Tricuspid atresia is typically associated with cyanosis rather than Mitral.

[Q: 141] OnExamination - Cardiology

A 65-year-old male is admitted with a two hour history of central chest pain associated with sweating and nausea. A myocardial infarction is suspected.

Which of the following is an indication for thrombolytic therapy?

- 1- 1mm ST elevation in leads V2-4
- 2- 1mm ST elevation in leads II, III and aVF.
- 3- 2mm ST depression in leads V2-4
- 4- T wave inversion in lead V3-5
- 5- Q waves in leads V2-4

Answer & Comments

Answer: 2- 1mm ST elevation in leads II, III and aVF.

There are two ECG criteria for initiating thrombolysis in a patient with suspected Myocardial Infarction. The first is the presence of ST elevation of at least 1mm in the limb leads or 2mm in the chest leads on the ECG and the second is new onset of left bundle branch block (LBBB.) Also, there must also be no compelling contraindications to thrombolysis.

[Q: 142] OnExamination - Cardiology

A 73-year-old male with type 2 diabetes requires improved glycaemic control. He also suffers from heart failure which is controlled with diuretic and ACEis.

Which of the following hypoglycaemic agents is contraindicated in this patient?

- 1- Acarbose
- 2- Glipazide
- 3- Netaglinide
- 4- Repaglinide
- 5- Rosiglitazone

Answer & Comments

Answer: 5- Rosiglitazone

Rosiglitazone can result in fluid retention of unknown aetiology which may cause a mild dilutional anaemia (haemoglobin typically falls

by 1 to 2 g/dl) and ankle oedema. It is contraindicated in hepatic dysfunction and congestive heart failure. Sulphonylureas are contraindicated in renal failure: all should be stopped and insulin started if serum creatinine exceeds 250 µmol/l. The recent United Kingdom Prospective Diabetes Study found no evidence that patients treated with sulphonylureas suffered cardiovascular events more often than those treated with insulin. Contraindications of Metformin include all the major organ failures- renal, hepatic, cardiac, and respiratory. It should not be used when serum creatinine concentration exceeds 150 µmol/l. Side-effects of Acarbose are due to carbohydrate malabsorption (flatus, abdominal bloating, gassy diarrhoea).

[Q: 143] OnExamination - Cardiology

In a patient presenting with aortic stenosis, which of the following findings would be most helpful in establishing a diagnosis of congenital bicuspid valve as the etiology?

- 1- age
- 2- calcified leaflets
- 3- commissural fusion on ECHO
- 4- negative history for rheumatic fever
- 5- systolic ejection click

Answer & Comments

Answer: 5- systolic ejection click

Age and calcified aortic root suggest calcific aortic valvular disease. Rheumatic AS results from fibrosis of the leaflets and fusion of the commissures. An ejection click or ejection sound, best heard at the apex, implies that the site of the stenosis is mostly valvular and of congenital origin i.e. bicuspid valvular disease.

[Q: 144] OnExamination -
Cardiology

A 32-year-old female who is 14 weeks pregnant in her third pregnancy is found to have a blood pressure of 152/88 mmHg. There are no other abnormalities of note on examination. She has a BMI of 33.3 kg/m² and urinalysis is otherwise normal. An ECG reveals left ventricular hypertrophy.

What is the most likely aetiology of her elevated blood pressure?

- 1- Essential Hypertension
- 2- Pre-eclampsia
- 3- Pregnancy induced hypertension
- 4- Secondary hypertension
- 5- White coat (Factitious) hypertension

Answer & Comments

Answer: 1- Essential Hypertension

This woman has hypertension which is discovered in her pregnancy but has evidence of LVH on her ECG suggesting that this is longstanding. Often, it takes at least two years of sustained hypertension to develop LVH and although her pregnancy may have contributed to any deterioration, the LVH suggests that it was pre-existent. The cause for her hypertension may be secondary but her high BMI is suggestive of it being essential.

[Q: 145] OnExamination -
Cardiology

A randomised, double-blind, placebo controlled trial of a cholesterol lowering drug in the primary prevention of coronary heart disease is reported.

1000 subjects are treated with the active drug, and 1000 are given placebo. They are followed up over a five year period and 100 individuals in the placebo group and 80 in the treatment group suffer a myocardial infarction.

What is the annual percentage risk of myocardial infarction in the group treated with placebo?

- 1- 0.5%
- 2- 2%
- 3- 5%
- 4- 8%
- 5- 10%

Answer & Comments

Answer: 2- 2%

Why this question is in the MRCP exam is anyone's guess! This is more of a mathematics exam.

In the 5 years 100 patients in the placebo group develop an MI. Assuming this is spread evenly across the years this means that 20 patients (out of 1000) suffer an MI each year. The annual risk is therefore 20/1000 = 0.02 which, expressed as a percentage is 2.

[Q: 146] OnExamination -
Cardiology

A 78-year-old diabetic female presented with a two day history of melena and dizziness. She had taken an unknown analgesic four days previously. On examination she was pale with a pulse of 90 beats per minute, a blood pressure of 100/65 mmHg and a lower midline scar from an operation for intermittent claudication three months previously. Investigations revealed:

haemoglobin 8 g/dL (13.0-18.0)
faecal occult blood strongly positive
upper gastrointestinal tract endoscopy:
normal

What is the most likely cause of her upper gastrointestinal haemorrhage?

- 1- aorto-enteric fistula
- 2- gastric erosions

- 3- gastric ulcer
- 4- Mallory-Weiss syndrome
- 5- Oesophageal varices

Answer & Comments

Answer: 1- aorto-enteric fistula

The upper GI endoscopy is normal, therefore GU, gastric erosions, varices and Mallory-Weiss syndrome are unlikely. The strongly positive FOB suggest significant GI haemorrhage. Aortoenteric fistulae (AEF) are now known to occur following endovascular repair of abdominal aortic aneurysms (AAA), and secondary to aortic grafting of any kind, presumably because of mechanical forces of dislodged or migrating devices. This patient may well have had an aorto-bifemoral graft, as treatment for peripheral vascular disease.

[Q: 147] OnExamination - Cardiology

A 38-year-old woman with a 10 year history of type 1 diabetes attends for annual review. She has background diabetic retinopathy, microalbuminuria with a urine Albumin:Creatinine ratio of 4.8 mg/dl (<3 mg/dl). Currently, she takes basal bolus insulin four times daily and lisinopril. She is a non-smoker, has a BMI of 30 kg/m² and a blood pressure of 124/70 mm/hg.

Investigations reveal:

Hba1c	7.3%	<6
Total Cholesterol	5.2 mmol/l	<5.2
Triglyceride	1.9 mmol/l	0.5-1.7
LDL-Cholesterol	3.3 mmol/l	<2.6
HDL-Cholesterol	1.3 mmol/l	0.7-1.7

Which would be the most appropriate treatment for this patient's lipid profile?

- 1- Ezetimibe
- 2- Fenofibrate
- 3- No treatment required

- 4- Omega-3 fatty acids
- 5- Simvastatin

Answer & Comments

Answer: 5- Simvastatin

Type 1 diabetes after a duration of 10 years is associated with a 2% annual CHD event rate, while the risk of cardiovascular events is increased in people with type 1 diabetes by factors such as co-existing microvascular complications, in particular nephropathy. Furthermore female gender is associated with an approximate 2 fold increase in relative CVD risk in type 1 diabetes, while other factors associated with increased CVD risk in type 1 diabetes include degree of glycaemia, duration of diabetes, as well as classically recognised factors such as hypertension and dyslipidaemia. The most recent CVD treatment guidelines JBS-2 advocate that treatment targets for LDL-C and TC of < 2 and < 4 mmol/l in all people with diabetes over the age of 40 years and in those under 40 where there are co-existing risk factors, i.e. poor glycaemic control (Hba1c > 9%), co-existing microvascular complications, presence of another CVD risk factor or features of the metabolic syndrome (NCEP ATP III). Therefore in this case simvastatin would be the most appropriate treatment choice aiming for a treatment TC < 4 mmol/l. Statins are however not licensed for use in pregnancy and women of child bearing age need to be counselled regarding pregnancy issues when initiating statin therapy. Repeat lipid profile is recommended 8 weeks following initiation of therapy to enable any therapeutic adjustments to be made.

[Q: 148] OnExamination - Cardiology

Which of the following is true regarding the action of Clopidogrel?

- 1- It inhibits cyclo-oxygenase

- 2- It is an ADP receptor antagonist
- 3- It is a glycoprotein IIb/IIIa inhibitor
- 4- It is a selective factor Xa inhibitor
- 5- It is Hydroxymethyl Coenzyme A inhibitor

Answer & Comments

Answer: 2- It is an ADP receptor antagonist

Clopidogrel prevents platelet aggregation through antagonism of the ADP receptor. It has been shown to reduce mortality from stroke and IHD in primary prevention studies.

[Q: 149] OnExamination - Cardiology

An 18-year-old man had repeated episodes of breathlessness and palpitations, lasting about 20 minutes and resolving gradually. There were no abnormal physical signs.

What is the most likely cause of these features?

- 1- Drug abuse
- 2- Panic disorder
- 3- Paroxysmal supraventricular tachycardia
- 4- Personality disorder
- 5- Thyrotoxicosis

Answer & Comments

Answer: 2- Panic disorder

Drug abuse is unlikely since the symptoms are quite short lived. We would expect other symptoms such as GI disturbance, headaches or hypertension to accompany a variety of drug abuse causes. Paroxysmal SVT would start and stop suddenly, not gradually. Personality disorder and thyrotoxicosis would both be expected to lead to symptoms of longer duration with other associated symptoms. This leaves 'panic disorder' as the most likely diagnosis.

[Q: 150] OnExamination - Cardiology

A 65-year-old woman is diagnosed as having subacute bacterial endocarditis and appropriate antibiotic therapy started.

Which of the following investigation is the most useful in order to monitor her response to antibiotics?

- 1- Serum bactericidal activity
- 2- Serial blood cultures
- 3- Serum C-reactive protein concentration
- 4- Serial full blood count, monitoring the white cell count
- 5- Serial transthoracic echocardiography

Answer & Comments

Answer: 3- Serum C-reactive protein concentration

CRP is a member of the pentraxin protein family, and levels are greatly elevated during acute inflammation. CRP augments the immune response to certain antigens, activates complement, and increases the monocytic production of certain tissue factors. CRP binds to bacterial surfaces, acting as an opsonin. CRP concentrations are elevated in almost all inflammatory, infectious, and malignant diseases. Serial measurements of CRP concentrations provide a simple, effective, non-invasive means of measuring response to antibiotic therapy.

[Q: 151] OnExamination - Cardiology

A 28-year-old man who is known to have Hypertrophic Cardiomyopathy has an out of hospital cardiac arrest and is successfully resuscitated.

What is the most appropriate mode of treatment?

- 1- Alcohol Septal Ablation
- 2- Amiodarone

- 3- Beta Blocker
- 4- Implantable Defibrillator
- 5- Myomectomy

Answer & Comments

Answer: 4- Implantable Defibrillator

Patients with HCM are at increased risk of sudden cardiac death due to VF/VT. Implantable Cardio Defibrillators (ICD) are superior to Amiodarone or Beta Blockers for preventing this. Reducing outflow tract obstruction with myomectomy or Alcohol Septal Ablation does not reduce the risk of SCD.

Other indications for ICD implantation include

1. Cardiac arrest due to VF/VT
2. Sustained VT causing haemodynamic compromise
3. Chronic Heart Failure, LVEF<40% and associated syncopal episodes due to Non Sustained VTPost-MI Non Sustained VT with LVEF<40%
4. Arrhythmogenic right ventricular cardiomyopathy causing cardiac arrest
5. Congenital Long QT with family history of sudden cardiac death at young age.

For European Society of Cardiology guidelines on ICD implantation visit:

<http://medc.uni-muenster.de/medc/dienstleistungen/public/PDF/icd-esc-guidelines-2001.pdf>

[Q: 152] OnExamination - Cardiology

A 17-year-old female is found to have a cardiac murmur characterized by a mid-systolic click. An echocardiogram reveals mitral insufficiency with upward displacement of one leaflet. There is also aortic root dilation to 4 cm. She has a dislocated right ocular

crystalline lens. She dies suddenly and unexpectedly. The medical examiner finds a prolapsed mitral valve with elongation, thinning, and rupture of chordae tendineae.

A mutation involving which of the following genes is most likely have be present in this patient?

- 1- Beta-myosin
- 2- CFTR
- 3- FGFR
- 4- Fibrillin
- 5- Spectrin

Answer & Comments

Answer: 4- Fibrillin

Marfan syndrome is a connective tissue disorder that is associated with floppy mitral valve and also with cystic medial necrosis that predisposes to aortic dissection. Abnormalities of the beta-myosin gene may be associated with some forms of dilated cardiomyopathy. The CFTR gene is associated with cystic fibrosis. The obstructive lung disease from widespread bronchiectasis that results from cystic fibrosis involving the lung can lead to pulmonary hypertension with cor pulmonale. The fibroblast growth factor receptor (FGFR) gene mutations can be associated with skeletal dysplasias. The spectrin gene mutation can be associated with red cell membrane abnormalities associated with hereditary spherocytosis. Anemias in adults with this condition are not typically severe, though anemias in general can increase cardiac stress.

[Q: 153] OnExamination - Cardiology

Which of the following is true regarding mitral stenosis?

- 1- it is tolerated well in pregnancy

- 2- there is characteristically a low wedge pressure
- 3- in AF, the opening snap disappears
- 4- The opening snap is not heard when the mitral valve is heavily calcified
- 5- Doppler U/S is usually inaccurate in determining severity

Answer & Comments

Answer: 4- The opening snap is not heard when the mitral valve is heavily calcified

Mitral stenosis is typically a consequence of childhood rheumatic fever but congenital disease is well recognised. It is associated with a tapping apex beat, a loud S1, Opening snap and Mid diastolic rumble with pre-systolic accentuation in those in sinus rhythm. The opening snap is characteristically lost with heavy valvular calcification. In particular Mitral stenosis is poorly tolerated in pregnancy due to volume overload. It is well characterised by doppler echocardiography.

[Q: 154] OnExamination - Cardiology

A middle aged woman presents with new onset palpitations. She also commented that she had lost weight recently despite an increased appetite. Examination reveals a goitre and a degree of exophthalmos. During physical examination, she fell unconscious. Blood pressure was 70/40 mmHg. Electrocardiogram revealed atrial fibrillation with rapid ventricular response.

What is the appropriate immediate management?

- 1- Anticoagulation
- 2- Carbimazole
- 3- DC cardioversion
- 4- Intravenous amiodarone
- 5- Intravenous propranolol

Answer & Comments

Answer: 3- DC cardioversion

The patient is haemodynamically compromised due to AF. The emergency management is DC cardioversion 200J → 360J → 360J. Adverse signs necessitating DC cardioversion are BP ? 90mmHg, chest pain, heart failure, impaired consciousness and heart rate ? 200bpm.

[Q: 155] OnExamination - Cardiology

A 67-year-old man presents with sudden onset atrial fibrillation (ventricular rate of 150/minute). His serum creatinine concentration was 250 umol/L (70-110).

What is the main factor that determines the choice of loading dose of digoxin in this patient?

- 1- Absorption
- 2- Apparent volume of distribution
- 3- Lipid solubility
- 4- Plasma half-life
- 5- Renal clearance

Answer & Comments

Answer: 5- Renal clearance

The pharmacokinetics of digoxin are complex and best explained by a two compartment model. The loading dose is mainly dependent on the Volume of Distribution of a drug but this patient has moderate renal failure. The loading dose is calculated (using various models) by taking into account age, creatinine clearance, body surface area etc. Volume of distribution becomes important particularly when body weight is 40kg or less. On balance it is the renal failure that is the most important factor in this patient in determining the loading dose.

Digoxin is cleared by the kidneys so the maintenance dose would require adjustment in renal failure.

[Q: 156] OnExamination -
Cardiology

A 65-year-old man is referred with abnormal liver function and undergoes a liver biopsy.

Which of the following count against hepatic cirrhosis?

- 1- Fibrous septa formation
- 2- Granuloma formation
- 3- Liver cell necrosis
- 4- Nodular regeneration
- 5- Subendothelial fibrosis

Answer & Comments

Answer: 2- Granuloma formation

Granuloma formation is not classically seen in cirrhosis, which can be micro or macronodular in type. In the micronodular form, the nodules are less than 3mm across with uniform liver involvement - seen in alcohol or biliary disease. In the macronodular form, there are larger nodules, classically seen in chronic viral hepatitis.)

See some examples

<http://www.meddean.luc.edu/lumen/MedEd/orfpath/cirrhosis.htm>

<http://www.pathology.vcu.edu/education/gi/lab3.h.html>

<http://radiology.uchc.edu/eAtlas/GI/578.htm>

[Q: 157] OnExamination -
Cardiology

In the consideration of cardiac tamponade, which of the following statements is most true?

- 1- Bradycardia is common

- 2- Early diastolic descent (y descent) is exacerbated
- 3- Pulsus paradoxus is pathognomonic
- 4- Renal failure is a recognised complication
- 5- The apex beat is always absent

Answer & Comments

Answer: 4- Renal failure is a recognised complication

Tachycardia is common in the presentation of cardiac tamponade, and the apex beat is frequently palpable. The y descent is absent, though pulsus paradoxus may or may not be present.

Pulsus paradoxus is defined as an inspiratory systolic fall in arterial pressure of 10mmHg or more. Pulsus paradoxus may also be present in massive PE, haemorrhagic shock, COPD and severe hypotension. Renal failure is a recognised complication of tamponade.

[Q: 158] OnExamination -
Cardiology

A 55-year old man presented with angina pectoris. His pain was relieved by Buccal Glyceryl Trinitrate 5mg. His discharge medication was Isosorbide Mononitrate 20mg bd.

Which factor accounts for the dose difference between these two formulations?

- 1- Absorption
- 2- First pass metabolism
- 3- Lipid solubility
- 4- Phase II (conjugation) metabolism
- 5- Plasma clearance

Answer & Comments

Answer: 1- Absorption

Buccal GTN is quickly converted to di- and mono-nitrates which have half-lives of 2

hours. Its effective duration of action is 30 minutes. It is metabolized by the liver to inorganic nitrite. ISMN is not subject to first pass metabolism in the liver. The overall half-life of isosorbide mononitrate is about 5 hours and that of GTN is two hours. Thus, this would result in a reduced dose of ISMN being required if related to plasma clearance. The sublingual route (which avoids first pass effect and the need for GI absorption) is the preferred route for achieving therapeutic effect quickly as GTN is absorbed efficiently by this route. However, the total dose administered by this route must be limited to avoid excessive effects. When a much longer duration is needed, oral preparations can be given that contain a sufficient amount of drug to result in sustained systemic blood levels.

[Q: 159] OnExamination -
Cardiology

A 60-year-old woman with a two year history of diet controlled type 2 diabetes was admitted with an acute myocardial infarction. She received thrombolysis together with an insulin infusion. Investigations revealed a fasting glucose of 12 mmol/l together with a cholesterol of 6.6 mmol/l.

Which of the following is the most appropriate treatment for her subsequent glycaemic control?

- 1- diet and exercise
- 2- Gliclazide
- 3- Metformin
- 4- Rosiglitazone
- 5- subcutaneous insulin

Answer & Comments

Answer: 5- subcutaneous insulin

The most appropriate treatment for her ongoing hyperglycaemia is a further three months of subcutaneous insulin as suggested by the DIGAMI study. This study revealed

significant reductions in mortality associated with the introduction of sliding scale insulin followed by three months of subcutaneous insulin in type 2 diabetics compared with traditional therapy consisting of their usual oral hypoglycaemic agents.

[Q: 160] OnExamination -
Cardiology

A 16-year-old female attends casualty 15 hours after ingesting approximately 30g of Paracetamol and 2g of Dihydrocodeine.

On examination, she is drowsy with a Glasgow Coma Scale of 15. Her pulse is 100 beats per minute, blood pressure is 110/66 mmHg and she has pinpoint pupils, with saturations of 96% on air.

What is the most appropriate treatment for this patient?

- 1- 10% Dextrose infusion
- 2- Activated charcoal by mouth
- 3- Gastric lavage
- 4- N-Acetylcysteine intravenously
- 5- Naloxone intravenously

Answer & Comments

Answer: 4- N-Acetylcysteine intravenously

This patient has taken a significant overdose of Paracetamol, and is presenting late at 15 hours. She is at risk of hepatocellular damage and needs to be commenced on an infusion of IV N-Acetylcysteine immediately. It is continued for 30 hours and sometimes beyond this, depending on results of Prothrombin time, Liver Function Tests, Urea and electrolytes, and glucose.

Activated charcoal is given to patients presenting within 1 hour of overdose. Flumazenil is reserved for reversal of benzodiazepine induced respiratory depression. Naloxone is used for opiate-induced respiratory depression.

[Q: 161] OnExamination -
Cardiology

A 15-year-old female presents following a sore throat with chest pain, fever, and a skin rash. Examination reveals a diastolic murmur. Her ASO titre is elevated.

Which of the following is a major criterion for the diagnosis of Rheumatic fever?

- 1- Fever
- 2- Raised ESR
- 3- Polyarthrititis
- 4- Migratory erythema
- 5- Prolonged PR interval

Answer & Comments

Answer: 3- Polyarthrititis

Polyarthrititis together with erythema marginatum, Sydenham's chorea, carditis and subcutaneous nodules constitute the major criteria associated with Rheumatic fever. Minor criteria include raised ESR, Arthralgia, pyrexia and a prolonged PR interval. Migratory erythema is associated with a glucagonoma.

[Q: 162] OnExamination -
Cardiology

A 52-year-old sales representative is admitted with an inferior myocardial infarction. He receives thrombolysis and makes an uneventful recovery. He is discharged on atenolol, aspirin and atorvastatin.

He enquires how long after his MI must he wait before he is able to drive?

- 1- One week
- 2- Two weeks
- 3- Four weeks
- 4- Three months
- 5- Six months

Answer & Comments

Answer: 3- Four weeks

The DVLA are quite clear on this issue. He must wait at least 4 weeks after his MI before he is able to drive. Similarly patients undergoing surgical revascularisation must also wait 4 weeks. If he was admitted with angina and underwent PTCA then he should wait one week.

[Q: 163] OnExamination -
Cardiology

A 58-year-old man has had an enlarging abdomen for several months. He has experienced no abdominal or chest pain. On physical examination he has a non-tender abdomen with no masses palpable, but there is a fluid thrill. An abdominal Ultrasound Scan shows a large abdominal fluid collection with a small cirrhotic liver. A chest X-ray shows a globally enlarged heart.

Which of the following conditions is most likely to be present?

- 1- Dilated cardiomyopathy
- 2- Lymphocytic myocarditis
- 3- Myocardial amyloid deposition
- 4- Nonbacterial thrombotic endocarditis
- 5- Severe occlusive coronary atherosclerosis

Answer & Comments

Answer: 1- Dilated cardiomyopathy

This man has alcoholic liver cirrhosis with ascites. The cardiomyopathy of alcoholism is a dilated or congestive form.

[Q: 164] OnExamination -
Cardiology

A previously well 27-year-old woman presents with a history of transient ischaemic attack affecting her right side and speech. She had returned to the United Kingdom from a

holiday in New Zealand two days previously. On examination there was nothing abnormal to find. An ECG, chest X-ray, CT brain scan and routine haematology and biochemistry were all normal.

What is the most likely underlying abnormality?

- 1- atrial myxoma
- 2- carotid artery stenosis
- 3- embolus from paroxysmal atrial fibrillation
- 4- patent foramen ovale
- 5- subarachnoid haemorrhage

Answer & Comments

Answer: 4- patent foramen ovale

This is a typical cause of stroke in a young person due to prolonged immobility. Deep vein thrombosis with patent foramen ovale will cause paradoxical embolism and stroke.

[Q: 165] OnExamination - Cardiology

A 69-year-old man is treated for chest infection. He has been on a stable dose of warfarin for the last six months as a treatment for atrial fibrillation, with INR recordings between 2-2.5. However, his most recent INR was 5.

Which one of the following drugs that has recently been started is likely to be responsible for the increased INR.

- 1- Clarithromycin
- 2- Co-dydramol
- 3- Digoxin
- 4- Rifampicin
- 5- Temazepam

Answer & Comments

Answer: 1- Clarithromycin

Clarithromycin induces the anticoagulant effect of warfarin whereas, rifampicin would reduce the anticoagulant effect. Ciprofloxacin and sulphonamides will also increase the anticoagulant effect of warfarin. Temazepam, digoxin and codeine have no appreciable effect.

[Q: 166] OnExamination - Cardiology

A 69-year-old woman admitted for a surgical procedure is noted to have a soft systolic murmur at the left sternal edge. Her ECG and chest X-ray were normal and transthoracic echocardiography revealed a small posterior pericardial effusion with normal valves.

Which of the following would be the most appropriate next step in this patient's management?

- 1- A diagnostic Pericardial aspiration
- 2- mammography
- 3- purified Protein derivative test for tuberculosis
- 4- reassurance
- 5- right heart catheterisation

Answer & Comments

Answer: 4- reassurance

The presence of a small pericardial effusion on echo is quite common and in this patient who otherwise appears well, no further action is required.

[Q: 167] OnExamination - Cardiology

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention study of ischaemic heart disease in a diabetic population. 1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period. In the

placebo group there were 150 Myocardial infarcts and in the group treated with the new statin there were 100 infarcts.

What is the annual percentage of myocardial infarction in the diabetic population treated with placebo?

- 1- 1%
- 2- 3%
- 3- 5%
- 4- 7%
- 5- 10%

Answer & Comments

Answer: 2- 3%

This study shows that there are 150 MIs in 1000 diabetic patients treated over a five year period in the placebo group. Hence the rate of infarction in this group is $150/1000=15\%$, divided by 5 years to give the annual MI rate of 3%.

[Q: 168] OnExamination - Cardiology

A study reports on the results of a large study of the primary prevention of stroke in a diabetic population using a new antiplatelet agent versus aspirin. The results of the study reveal that over a 5 year period the incidence of stroke in the aspirin treated group is 3% compared to a rate of 1.5% in the group treated with the new antiplatelet agent ($p<0.001$).

What is the relative risk reduction in stroke associated with the new drug?

- 1- 1.5%
- 2- 15%
- 3- 30%
- 4- 40%
- 5- 50%

Answer & Comments

Answer: 5- 50%

The relative risk reduction is another calculation important for the interpretation of publications. In this case there is an absolute risk reduction of 1.5% ($3 - 1.5\%$) in stroke afforded by the new agent compared with aspirin yet the relative risk reduction is $1.5/3=50\%$. That is 50% fewer strokes may be prevented by the use of the newer agent compared with aspirin, although this would be the equivalent of 15 per 1000 patients treated (30 strokes expected/1000 patients treated with aspirin but only 15 with the new drug).

[Q: 169] OnExamination - Cardiology

A 30-year-old man presented with a history of transient loss of consciousness and palpitation. His ECG showed ventricular tachycardia.

Which one of the following treatments should be avoided?

- 1- Adenosine
- 2- Amiodarone
- 3- DC cardioversion
- 4- Flecainide
- 5- Verapamil

Answer & Comments

Answer: 5- Verapamil

Verapamil may cause fatal hypotension in VT (due to negative inotropic and peripheral vasodilatory effects). Flecaïnide should be used with caution because it may produce an incessant form of VT, which is difficult to control. Adenosine is used to differentiate SVT with right (or left), bundle branch block from VT.

[Q: 170] OnExamination -
Cardiology

A 40-year-old female with mitral stenosis consults for advice regarding operative procedures.

In which of the following circumstances would antibiotic prophylaxis of infective endocarditis be required?

- 1- Cardiac catheterisation
- 2- Caesarian section
- 3- Dental scaling
- 4- Removal of a lipoma
- 5- Termination of pregnancy

Answer & Comments

Answer: 3- Dental scaling

Dental scaling is regarded as a high risk procedure and should be covered by antibiotic prophylaxis.

[Q: 171] OnExamination -
Cardiology

A 27-year-old woman complained of palpitations, breathlessness and chest pain, radiating to the left arm. These symptoms had developed six weeks previously, after she had witnessed her father dying from a myocardial infarction. In the past 10 years she had been investigated for abdominal pain, headaches, joint pains, and dyspareunia, without serious cause being found for these symptoms.

What is the most likely diagnosis?

- 1- Depressive episode
- 2- Factitious disorder
- 3- Generalized anxiety disorder
- 4- Obsessive compulsive disorder
- 5- Somatization disorder

Answer & Comments

Answer: 5- Somatization disorder

Although the brief scenario does not have quite enough criteria to fulfill a diagnosis there is enough to make somatization disorder the most likely answer. Somatization disorder is characterized by multiple recurring pains and gastrointestinal, sexual, and pseudo-neurologic symptoms that occur over a period of years. To meet the diagnostic criteria for somatization disorder, the patients' physical complaints must not be intentionally induced and must result in medical attention or significant impairment in social, occupational, or other important areas of functioning. By definition, the first symptoms appear in adolescence and the full criteria are met by 30 years of age. Of all the other disorders "factitious disorder" would seem the least likely. The other three are possible explanations but not as likely as somatization.

[Q: 172] OnExamination -
Cardiology

A 16-year-old male presents with acute severe asthma. On examination his peripheral pulse volume fell during inspiration.

Which one of the following is the most likely explanation for this clinical sign?

- 1- The cardiac effect of high dose beta agonist bronchodilator drugs
- 2- A falling heart rate on inspiration
- 3- Myocardial depression due to hypoxia
- 4- Peripheral vasodilatation
- 5- Reduced left atrial filling pressure on inspiration

Answer & Comments

Answer: 5- Reduced left atrial filling pressure on inspiration

This patient is demonstrating pulsus paradoxus. The right heart responds directly to changes in intrathoracic pressure, while the filling of the left heart depends on the

pulmonary vascular volume. At high respiratory rates, with severe air flow limitation (eg acute asthma) there is an increased and sudden negative intrathoracic pressure on inspiration and this will enhance the normal fall in blood pressure.

[Q: 173] OnExamination - Cardiology

A 70-year-old woman with established aortic stenosis attends for annual review.

Which one of the following factors is the most important in deciding the timing of surgery?

- 1- Aortic valve gradient of 50 mmHg
- 2- Left ventricular hypertrophy
- 3- Valvular calcification
- 4- The Patient's symptomatology
- 5- The intensity of the murmur

Answer & Comments

Answer: 4- The Patient's symptomatology

The patient's symptomatology is probably the most important determinant in terms of the decision to operate. Dyspnoea, chest pain and syncope are all features of aortic stenosis and when present suggest a poor prognosis if left. A gradient of 50mmHg would be regarded as moderate - severe aortic stenosis but if asymptomatic nothing would be done. LVH is a common feature of AS and does not influence the decision for surgery. Calcific aortic disease is not of itself important and the gradient should be considered.

[Q: 174] OnExamination - Cardiology

A 54-year-old man presents with central crushing chest pain. Examination is normal. 12-lead ECG shows ST segment elevation in leads II, III, aVF and ST depression in V1, V2 and V3.

Which coronary artery is occluded?

- 1- Circumflex
- 2- Left Anterior Descending
- 3- Left Main Stem
- 4- Obtuse Marginal
- 5- Right Coronary Artery

Answer & Comments

Answer: 5- Right Coronary Artery

The ECG describes an infero-posterior MI. This territory is supplied by a dominant Right Coronary Artery. The concept of coronary dominance refers to which coronary artery supplies the posterior descending coronary artery. In the case of approximately 85% of patients this is the right coronary artery with about 15% of patients having a dominant left circumflex. The territories supplied by the arteries are as follows:

" Circumflex: Lateral

" Left Anterior Descending: Anterior and septum

" Left Main Stem: Branches into the Left Anterior Descending artery and Circumflex and supplies most of the left ventricle. Complete Left Main Stem occlusion is invariably fatal.

" Obtuse Marginal: One of the branches of the circumflex and supplies the 'high lateral' region of the left ventricle (ECG leads I and aVR).

Basic understanding of coronary anatomy is important, as this is predictive of problems following MI. For example, the right coronary artery supplies the AV node, so heart block following inferior MI is common. However, heart block following anterior MI is a grave prognostic marker as this indicates a large anterior wall infarct. The right coronary system also supplies the right ventricle, hence problems relating to a right ventricular infarct are commonly associated with an inferior MI.

[Q: 175] OnExamination -
Cardiology

Which of the following anti-microbials is associated with prolongation of the QT interval?

- 1- Co-amoxiclav
- 2- Gentamicin
- 3- Cefuroxime
- 4- Erythromycin
- 5- Isoniazid

Answer & Comments

Answer: 4- Erythromycin

The macrolides are associated with a prolongation of the QT interval. Other antimicrobials associated with prolonged QT include quinine, levofloxacin.

[Q: 176] OnExamination -
Cardiology

A 57-year-old man develops deep venous thrombosis during a hospitalization for prostatectomy. He exhibits decreased mental status with right hemiplegia, and a CT scan of the head suggests an acute cerebral infarction in the distribution of the left middle cerebral artery. A chest X-ray reveals cardiac enlargement and prominence of the main pulmonary arteries that suggests pulmonary hypertension. His serum troponin I is <0.4 ng/mL.

Which of the following lesions is most likely to be present on echocardiography?

- 1- Coarctation of the aorta
- 2- Dextrocardia
- 3- Pulmonary stenosis
- 4- Tetralogy of Fallot
- 5- Ventricular septal defect

Answer & Comments

Answer: 5- Ventricular septal defect

This is 'paradoxical embolus' from right to left. This can only happen if there is a defect that allows passage from right-to left. This can happen across a patent foramen ovale. In this case, the pulmonary hypertension suggests that there may have been a shunt persistent for a long time - Eisenmenger complex. An atrial or a ventricular septal defect can provide the shunt.

[Q: 177] OnExamination -
Cardiology

During auscultation of the heart you discover a wide fixed splitting of the second heart sound.

In which of the following conditions does this occur?

- 1- an uncomplicated ASD
- 2- Fallot's tetralogy
- 3- aortic stenosis
- 4- Right Bundle Branch Block
- 5- constrictive pericarditis

Answer & Comments

Answer: 1- an uncomplicated ASD

There is a single sound in Fallot's because of an absent P2. Aortic stenosis leads to reversed splitting (also seen with LBBB and ventricular pacemaker). In RBBB there is wide splitting of S2 but it is not fixed.

[Q: 178] OnExamination -
Cardiology

A 65-year-old male with left ventricular systolic dysfunction was dyspnoeic on climbing stairs but not at rest. The patient was commenced on Ramipril and Furosemide.

Which one of the following drugs would improve the patient's prognosis further?

- 1- Amiodarone
- 2- Digoxin
- 3- Diltiazem
- 4- Metoprolol
- 5- Isosorbide Mononitrate

Answer & Comments

Answer: 4- Metoprolol

This patient has NYHA grade II heart failure and is already receiving ACE-Inhibitors and diuretics. Studies such as CIBIS, MERIT HF and COPENICUS clearly demonstrate the advantage of beta blockers even with severe heart failure.

[Q: 179] OnExamination - Cardiology

A 17-year-old girl is short in stature for her age. She has not shown any changes of puberty. She has a webbed neck. Her vital signs include Temperature 36.6° Respiratory rate 18/min Pulse 75 bpm and BP 165/85 mmHg. On physical examination, she has a continuous murmur heard over both the front of the chest as well as her back. Her lower extremities are cool with poor capillary filling. A chest radiograph reveals a prominent left heart border, no oedema or effusions, and rib notching.

Which of the following pathologic lesions best explains these findings?

- 1- Constriction of the aorta past the ductus arteriosus
- 2- Lack of development of the spiral septum and partial absence of conus musculature
- 3- Shortening and thickening of chordae tendineae of the mitral valve
- 4- Single large atrioventricular valve
- 5- Supravalvular narrowing in the aortic root

Answer & Comments

Answer: 1- Constriction of the aorta past the ductus arteriosus

She has coarctation of the aorta, and the constriction is postductal, allowing prolonged survival. Her physical characteristics also suggest Turner syndrome (monosomy X).

[Q: 180] OnExamination - Cardiology

A 65-year-old man has longstanding stable heart failure treated with furosemide and enalapril. He complains of swelling in his left knee and his GP treats him with Celecoxib, a cyclo-oxygenase-2 (COX-2) inhibitor. Two weeks later the patient has increasing breathlessness and ankle oedema.

Which one of the following effects of celecoxib is the most likely to explain his symptoms?

- 1- decreased absorption of furosemide from the gut
- 2- decreased myocardial contractility
- 3- reduced effective action of enalapril
- 4- the onset of anaemia
- 5- the onset of fluid retention

Answer & Comments

Answer: 5- the onset of fluid retention

Celecoxib (rofecoxib has been withdrawn) acts by inhibiting prostaglandin synthesis via inhibition of cyclooxygenase-2 (COX-2). It causes fluid retention and can worsen an already pre-existing heart failure as in this case. The CSM reminds prescribers that celecoxib is contraindicated in patients with severe congestive heart failure, active peptic ulceration or GI bleeding.

[Q: 181] OnExamination - Cardiology

A 50-year-old male is admitted with a 3 hour

history of central chest pain sweating and nausea. He has no relevant past medical history although his father died of an MI at the age of 48 and he is a smoker of 5 cigarettes per day. He currently takes no medication. He is seen in the morning on the consultant ward round 12 hours after admission and his pain has now settled. Examination reveals no specific abnormality and his ECG is normal.

Which of the following investigations would be most appropriate for this patient?

- 1- Coronary Angiography
- 2- Echocardiography
- 3- Endoscopy
- 4- Exercise ECG
- 5- Troponin T

Answer & Comments

Answer: 5- Troponin T

This smoker has a good history of angina and a strong family history of IHD. The most appropriate investigation would be a troponin T concentration would be highly specific and sensitive for IHD if elevated. An exercise test is relevant only after an acute coronary event has been excluded (by troponin T). If positive then angiography should be performed.

[Q: 182] OnExamination - Cardiology

Concerning complete atrioventricular septal defects which of the following statements is true?

- 1- are seen frequently in patients with trisomy 21
- 2- frequently have aortic valve insufficiency
- 3- have a normal mitral valve structure
- 4- include a coronary sinus atrial septal defect
- 5- include a perimembranous ventricular septal defect

Answer & Comments

Answer: 1- are seen frequently in patients with trisomy 21

Partial AV canal defect or ostium primum ASD

Complete AV septal defect Large deficiency in the atrial and ventricular septa. Commonly AV valve orifice and the commonest defect associated with Down's syndrome.

[Q: 183] OnExamination - Cardiology

A 60-year-old male diabetic presents to clinic for advice on prevention of a further heart attack after having sustained a myocardial infarction five years previously. He takes metformin 500 mg tds, bendroflumethiazide 2.5 mg daily and aspirin 150 mg daily. His body mass index was 33.5 kg/m², with a pulse of 82 beats per minute regular and a blood pressure of 152/92 mmHg. His cholesterol concentration is 3.3 mmol/l (< 5.5).

What is the most appropriate strategy for this patient?

- 1- 24 hour ambulatory ECG
- 2- Atorvastatin
- 3- Increase aspirin from 150 mg to 300 mg daily
- 4- Orlistat
- 5- Ramipril

Answer & Comments

Answer: 5- Ramipril

The most appropriate strategy for secondary prevention would involve further blood pressure reduction with an ACEi which would not only reduce CV risk as suggested by the HOPE study but also reduce microvascular risk as revealed by UKPDS. The NCEP ATP III criteria suggest a cholesterol less than 4 and this patient already has a low and would not benefit as much from the addition of a statin.

The increase of aspirin from 150 to 300 mg would offer no added advantage. Orlistat is used under specific criteria for weight reduction and has, as yet, not been shown to reduce CV risk in T2DM. There's no reason here for a 24 hr tape.

[Q: 184] OnExamination - Cardiology

A study reveals an immediate rise in blood pressure following infusion of a hormone in normal volunteers.

Which of the following is the most likely hormone used in this study?

- 1- angiotensin I
- 2- angiotensin II
- 3- atrial natriuretic peptide (ANP)
- 4- brain natriuretic peptide (BNP)
- 5- prolactin

Answer & Comments

Answer: 2- angiotensin II

Angiotensin II when infused intravenously produces an immediate rise in blood pressure being a potent vasoconstrictor. Both BNP and ANP result in natriuresis and lowering of blood pressure. Prolactin has no specific effect.

[Q: 185] OnExamination - Cardiology

Which ONE of the following is a contraindication to thrombolysis?

- 1- age over 75 years
- 2- the presence of atrial fibrillation
- 3- asthma
- 4- pregnancy
- 5- background diabetic retinopathy

Answer & Comments

Answer: 4- pregnancy

Those over 75 years benefit as much or more than younger MI patients from thrombolysis. Proliferative diabetic retinopathy is a relative contraindication. Important contraindications to thrombolysis include pregnancy, GI bleeding, heavy vaginal bleeding, recent stroke or surgery, uncontrolled severe hypertension, GI malignancy and prolonged CPR (more than half an hour).

[Q: 186] OnExamination - Cardiology

A 19-year-old girl presents with recurrent episodes of loss of consciousness.

Over the last two years she has had blackouts which last approximately 2 minutes. They typically occur when she is standing. These have occurred more frequently over the last week. The last episode was witnessed by her boyfriend who noted that she collapsed without any abnormal movements. On coming round she was rather drowsy initially but generally fine and recovered relatively quickly.

What is the most likely diagnosis?

- 1- Addison's disease
- 2- Atonic seizures
- 3- Cardiac syncope
- 4- Complex partial seizures
- 5- Vasovagal syncope

Answer & Comments

Answer: 5- Vasovagal syncope

This young girl has features suggestive of vasovagal syncope. The story suggests that the episodes always occur when she is standing (whereas cardiac syncope could occur at any time but may be precipitated by exercise), that there are no abnormal movements (making epilepsy less likely) and that there is a pretty full recovery (again making epilepsy less likely).

[Q: 187] OnExamination -
Cardiology

A 65-year-old woman undergoes temporary pacing due to complete heart block following acute myocardial infarction.

Which coronary artery is most likely to have been occluded?

- 1- Anterior descending
- 2- Circumflex
- 3- Left main coronary
- 4- Obtuse marginal
- 5- Right coronary

Answer & Comments

Answer: 5- Right coronary

Myocardial infarction complicated by bradycardia is most commonly seen in inferior wall myocardial infarction. This area of the heart is supplied by the Right coronary artery. The right coronary artery gives off branches to the sinus node and AV node therefore disease within this vessel can cause damage to the cardiac conducting system and can therefore lead to bradyarrhythmias.

[Q: 188] OnExamination -
Cardiology

Which of the following investigations is used to monitor the treatment of infective endocarditis?

- 1- Blood culture
- 2- C Reactive Protein
- 3- Echocardiography
- 4- Erythrocyte Sedimentation Rate
- 5- Serum bactericidal titres of antibiotics

Answer & Comments

Answer: 2- C Reactive Protein

Serum bactericidal titres against the infecting organism are no longer recommended. There

was always great variation in the monitoring methods used for these tests and in the interpretation of their results. At best they could only predict bacteriological not clinical cure and bacteriological failure is very rare. The most useful laboratory test for monitoring the response to treatment (which is usually obvious clinically) is serial C-reactive protein estimation. This is of much more use than the erythrocyte sedimentation rate, which is much slower to fall.

[Q: 189] OnExamination -
Cardiology

A 70-year-old male was receiving amiodarone 200 mg daily for intermittent atrial fibrillation. However, he was aware of tiredness and lethargy. He appeared clinically euthyroid with no palpable goitre. Investigations revealed:

Serum Free T₄ 23pmol/L (9-26)

Serum total T₃ 0.8 nmol/L (0.9-2.8)

Serum TSH 8.2 mU/L (<5)

Which of the following statements would explain these results?

- 1- Abnormal thyroxine binding globulin
- 2- Amiodarone-induced hypothyroidism
- 3- 'sick euthyroid' syndrome
- 4- Spontaneous hypothyroidism
- 5- TSH secreting pituitary adenoma

Answer & Comments

Answer: 2- Amiodarone-induced hypothyroidism

The results show normal T₄, low T₃ with elevated TSH. These results are typical of amiodarone induced hypothyroidism which inhibits the peripheral conversion of T₄ to T₃.

[Q: 190] OnExamination -
Cardiology

You wish to calculate a patient's ejection

fraction as the patient complains of dyspnoea.

Which of the following echocardiographic measures would be mandatory?

- 1- Aortic valve peak velocity
- 2- Pulse wave of mitral inflow
- 3- Left ventricular end diastolic diameter
- 4- M-mode of the mitral valve
- 5- M-mode of the aortic valve

Answer & Comments

Answer: 3- Left ventricular end diastolic diameter

One way of measuring ejection fraction is estimated by the ratio between the M-mode readings of the left ventricular end diastolic diameter divided by the end systolic diameter.

[Q: 191] OnExamination - Cardiology

An elderly man with a history of asthma, congestive heart failure, and peptic ulcer disease is admitted with bronchospasm and rapid atrial fibrillation. He receives frequent nebulised salbutamol and IV digoxin loading, his regular medications are continued. 24 hours after admission his serum potassium is noted to be 2.8 mmol/l.

Which of his medications is most likely to have caused this abnormality.

- 1- Digoxin
- 2- ACE inhibitor
- 3- Salbutamol
- 4- Ranitidine
- 5- Spironolactone

Answer & Comments

Answer: 3- Salbutamol

Salbutamol given in regular nebulised doses or IV is commonly associated with hypokalaemia. Spironolactone and ACE inhibitors commonly

cause hyperkalaemia (their use in combination is potentially dangerous and requires regular monitoring of serum electrolytes). Electrolyte disturbance with Ranitidine is very uncommon. Digoxin doesn't cause hypokalaemia (unless due to vomiting associated with digoxin toxicity). Hypokalaemia (usually diuretic induced) does increase cardiac sensitivity to Digoxin and correction of hypokalaemia is recommended to avoid arrhythmias.

[Q: 192] OnExamination - Cardiology

A 16-year old girl was incidentally found to have delta wave on ECG suggestive of Wolff-Parkinson-White syndrome. There was no tachycardia and she was asymptomatic.

What is the next step in management?

- 1- Beta-blocker therapy
- 2- Electrophysiological study and provocation of arrhythmia
- 3- Radiofrequency catheter ablation of the bypass tract
- 4- Reassurance
- 5- Repeat ECG

Answer & Comments

Answer: 4- Reassurance

The ECG appearances of a delta wave occur in approximately 1.5 per 1000 of the population, but many individuals never experience paroxysmal tachycardias. The degree of pre-excitation during sinus rhythm is variable: it may be intermittent if the refractory period of the accessory pathway is close to the sinus cycle length, or inapparent if the delta wave is obscured due to rapid AV nodal conduction. Radiofrequency catheter ablation of bypass tracts is possible in >90% of patients and is the treatment of choice in patients with symptomatic arrhythmias.

[Q: 193] OnExamination -
Cardiology

A 55-year-old woman has had worsening shortness of breath for several years. She now has to sleep sitting up on two pillows. She has difficulty swallowing. There is no history of chest pain. She is afebrile. Recently, she suffered a stroke with left hemiparesis. A chest X-ray reveals a near-normal left ventricular size with a prominent left atrial border.

Which of the following conditions is most likely to account for these findings?

- 1- Aortic coarctation
- 2- Cardiomyopathy
- 3- Essential hypertension
- 4- Left renal artery stenosis
- 5- Mitral valve stenosis

Answer & Comments

Answer: 5- Mitral valve stenosis

Mitral valve stenosis leads to left atrial enlargement, but the left ventricle is usually small. An enlarged left atrium may lead to pressure posteriorly on the oesophagus. Most mitral valvular disease in adults results from rheumatic heart disease.

[Q: 194] OnExamination -
Cardiology

A 74-year-old man presented with acute pain, pallor and absent pulses in his right leg. Investigations revealed an embolus in his femoral artery.

What is the most likely source of this embolus?

- 1- marantic endocarditis
- 2- paradoxical emboli
- 3- rheumatic endocardial vegetations
- 4- right ventricular thrombi
- 5- thrombi from an atheromatous aorta

Answer & Comments

Answer: 5- thrombi from an atheromatous aorta

Ulceration of an atheromatous plaque of the abdominal aorta is the most common source of emboli in this situation. Right ventricular thrombi would embolise to the lung. The others are possible but less likely causes.

[Q: 195] OnExamination -
Cardiology

A 65-year-old female presents with heart failure. Her echocardiogram shows a restrictive cardiomyopathy but with structurally normal valves.

Which one of the following is the most likely cause?

- 1- amyloidosis
- 2- coxsackie infection
- 3- Down's syndrome
- 4- Marfan's syndrome
- 5- Turner's syndrome

Answer & Comments

Answer: 1- amyloidosis

The diagnosis is amyloidosis which causes an infiltrative restrictive cardiomyopathy typically in patients of this age group. Other causes include sarcoidosis, radiotherapy, systemic sclerosis and carcinoid syndrome. Cocksackie produces a viral myocarditis with the likelihood of a dilated appearance on echo. Marfan's is likely to cause valvular regurgitant defects and a dilated cardiomyopathy. Down's syndrome is more likely to be associated with AV canal defects and consequent dilatation. Turner's syndrome is associated with atrial septal defects and co-arctation and bicuspid valvular defects.

[Q: 196] OnExamination -
Cardiology

A 72-year-old woman presented with acute severe chest pain with an ECG revealing ST segment elevation in leads II, III and aVF. She was treated with thrombolysis but two days later became acutely unwell. Examination revealed a loud systolic murmur at the apex which radiated into the axilla with associated pulmonary oedema.

What is the most likely diagnosis?

- 1- Acute left ventricular failure
- 2- Cardiogenic shock
- 3- pericarditis
- 4- Ruptured papillary muscle
- 5- Ventricular septal defect

Answer & Comments

Answer: 4- Ruptured papillary muscle

The most likely explanation in this patient with a prior inferior myocardial infarct is mitral valve prolapse due to papillary muscle rupture.

[Q: 197] OnExamination -
Cardiology

A 21 year-old woman has a history of palpitations and light headedness. ECG shows short PR interval and inferior Q waves. Her symptoms improve with atenolol 25 mg/day but she has had two short episodes of similar symptoms in the previous 24 hours.

What is the long-term management of choice?

- 1- Anticoagulation.
- 2- Oral amiodarone.
- 3- Oral digoxin.
- 4- Increase the dose of atenolol.
- 5- Radiofrequency ablation.

Answer & Comments

Answer: 5- Radiofrequency ablation.

WPW can be associated with negative delta waves in II, III and aVF. The longterm management of choice is ablation of the accessory pathway.

[Q: 198] OnExamination -
Cardiology

A 56-year-old male with left ventricular systolic dysfunction was dyspnoeic on climbing stairs but not at rest. The patient was commenced on ramipril and furosemide.

Which one of the following drugs would improve the patient's prognosis?

- 1- Amiodarone
- 2- Amlodipine
- 3- Bisoprolol
- 4- Digoxin
- 5- Nitrate therapy

Answer & Comments

Answer: 3- Bisoprolol

This patient has NYHA stage II heart failure. Studies such as CIBIS-II and MERIT-HF reveal that β -blockers significantly reduce morbidity and mortality in heart failure.

[Q: 199] OnExamination -
Cardiology

A 58-year-old man presents with sudden onset chest pain. He has a known history of ischaemic heart disease. ECG shows ST segment elevation in V1-V5 without reciprocal depression.

In which territory is the infarction most likely to have take place?

- 1- Anterior
- 2- Inferior
- 3- Lateral

4- Inferio-lateral

5- Posterior

Answer & CommentsAnswer: 1- Anterior

This MI is likely to be in the LAD and represents an anterior MI.

**[Q: 200] OnExamination -
Cardiology**

A 65-year-old man presents with severe central crushing chest pain. ECG shows evidence of an inferior myocardial infarction. He receives TPA, Heparin and Aspirin. Four hours after initial presentation, he starts feeling dizzy and breathless. His pulse is 40 bpm regular, BP 80/50. Heart sounds are soft and chest clear to auscultation. ECG shows 2:1 AV block with T wave inversion inferiorly. IV atropine was administered but had no effect.

What is the next most important treatment?

- 1- IV Dopamine.
- 2- IV Isoprenaline.
- 3- Insert a permanent pacemaker.
- 4- Insert a temporary pacemaker.
- 5- Monitor his progress.

Answer & CommentsAnswer: 4- Insert a temporary pacemaker.

This patient has had an inferior MI which is commonly associated with conduction abnormalities. He now develops heart block which leaves him bradycardic, symptomatic and with a low BP. Isoprenaline is contraindicated in acute MI due to its positive inotropic effects and arrhythmogenic potential. A temporary wire would deal with the situation until the inferior MI has fully resolved. He is unlikely to need a Permanent Pacemaker.

**[Q: 201] OnExamination -
Cardiology**

A 29-year-old female attends A&E complaining of acute onset of palpitations. She is attached to a cardiac monitor and her pulse rate is 180bpm. She is warm and well perfused, her BP is 135/80 mmHg, respiratory rate 20/min, oxygen saturation 100% on air and on auscultation her chest is clear with no evidence of cardiac failure. ECG shows a narrow complex tachycardia. Carotid massage and valsalva manoeuvre have failed to attenuate the rhythm disturbance.

What is the appropriate initial management?

- 1- DC Cardioversion
- 2- IV Adenosine
- 3- IV Amiodarone
- 4- IV Digoxin
- 5- IV Magnesium

Answer & CommentsAnswer: 2- IV Adenosine

This patient has a narrow complex supraventricular tachycardia. From history and examination she is not haemodynamically compromised and, therefore, initial management would be IV adenosine in the absence of contraindication (e.g. asthma) in order to create a transient conduction delay. This may terminate the tachycardia, or cause a slowing in rate to allow identification of the underlying rhythm, to guide optimal anti arrhythmic therapy. If the patient had chest pain, hypotension, SBP <90 mmHg, or evidence of cardiac failure, then DC cardioversion is indicated.

**[Q: 202] OnExamination -
Cardiology**

A 48-year-old male is referred with impotence. He has a history of angina, hypertension and type 2 diabetes.

Which one of the following drugs that he takes would present a contra-indication to him be able to receive Sildenafil?

- 1- Aspirin
- 2- Bendroflumethiazide
- 3- Isosorbide Mononitrate
- 4- Lisinopril
- 5- Metformin

Answer & Comments

Answer: 3- Isosorbide Mononitrate

Nitrates and Sildenafil are contra-indicated due to the precipitant drops in blood pressure. Viagra is also associated with increases in intra-ocular pressure so should be avoided in glaucoma, hereditary retinal disease and in those with hypotension.

[Q: 203] OnExamination - Cardiology

A 72-year-old man with type II diabetes mellitus presented following the sudden onset of palpitations. An ECG revealed rapid atrial fibrillation. He was commenced on Amiodarone but the atrial fibrillation persisted.

Which of the following has been shown to be of greatest benefit in reducing his future risk of vascular events?

- 1- Anticoagulation
- 2- Aspirin
- 3- Continuation of Amiodarone
- 4- DC cardioversion
- 5- Digoxin

Answer & Comments

Answer: 1- Anticoagulation

Both sustained and paroxysmal atrial fibrillation are associated with a relatively high incidence of thromboembolism and stroke.

Clinical trials have demonstrated that warfarin reduces the risk of stroke in patients with AF. This benefit outweighs the risk of bleeding.

[Q: 204] OnExamination - Cardiology

A 63-year-old man presents with recurrent pleural effusions. His Chest X-ray is shown.

On examination in clinic his hands showed the following.

What is the diagnosis?

- 1- Chronic Mucocutaneous Candidiasis
- 2- Iron deficiency
- 3- Ochronosis
- 4- Polychondritis
- 5- Yellow Nail Syndrome

Answer & Comments

Answer: 5- Yellow Nail Syndrome

This is Yellow Nail Syndrome where the nails are yellow, thickened, curved, stop growing and may become detached from the nailbed. Associated findings include lymphoedema, bronchiectasis and pleural effusions.

[Q: 205] OnExamination - Cardiology

A 63-year-old male is admitted with a 30 minute history of central chest pain associated with nausea and sweating. His ECG reveals ST elevation in leads II, III and aVF.

Which of the following coronary arteries is most likely to be occluded?

- 1- Circumflex artery
- 2- Left anterior descending artery
- 3- Obtuse marginal artery
- 4- Posterolateral artery
- 5- Right coronary artery

Answer & Comments

Answer: 5- Right coronary artery

The patient has had an inferior MI and this is most likely due to occlusion of the right coronary artery. LAD occlusion results in anterior infarction; circumflex or lateral branch of the LAD results in lateral infarction. RCA occlusion may also cause posterior infarction

[Q: 206] OnExamination - Cardiology

A 42 year-old male admitted with dyspnoea is noted to have a murmur suggestive of mitral stenosis.

The presence of which of the following clinical signs suggests that the mitral valve is mobile?

- 1- fourth heart sound
- 2- loud second heart sound
- 3- opening snap
- 4- a soft first heart sound
- 5- a third heart sound

Answer & Comments

Answer: 3- opening snap

Features of Mitral stenosis include the loud first heart sound, opening snap and if in sinus rhythm, a pre-systolic accentuation. Calcification of the valve results in immobility and loss of the opening snap.

[Q: 207] OnExamination - Cardiology

A 62-year-old male undergoes cardioversion for idiopathic atrial fibrillation. Post-procedure he was shown to be in sinus rhythm. Medication at admission included Warfarin digoxin and atenolol which he had been taking for the last six weeks.

Which of the following agents should he continue to take until he is seen in clinic in six weeks time.

- 1- Aspirin
- 2- Atenolol
- 3- Digoxin
- 4- Sotalol
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

This patient has undergone successful cardioversion for idiopathic AF and needs to remain on warfarin as his risk of further thromboembolism as his Atria are now contracting normally remains high up until six weeks after achieving sinus rhythm. Digoxin is not required post procedure as neither it nor atenolol maintain sinus rhythm. Aspirin is not as good as warfarin in preventing thromboembolic disease. Sotalol, like amiodarone is good at chemical cardioversion and maintaining SR but its role post cardioversion is uncertain.

[Q: 208] OnExamination - Cardiology

A 76-year-old woman presented with an acute myocardial infarction. The ECG showed ST segment elevation in leads II, III and a VF.

Which coronary artery is most likely to be occluded?

- 1- Circumflex artery
- 2- Diagonal branch of the left anterior descending artery
- 3- Left anterior descending artery
- 4- Left Coronary artery
- 5- Right coronary artery

Answer & Comments

Answer: 5- Right coronary artery

This patient has an inferior myocardial infarction which is usually due to occlusion of the Right Coronary artery and less commonly Circumflex occlusion may be responsible.

[Q: 209] OnExamination - Cardiology

A 60-year-old man with a past history of controlled hypertension presents with acute onset weakness of his left arm, that resolved over 12 hours. He had suffered two similar episodes over the last three months. Examination reveals a blood pressure of 132/82 mmHg and he is in atrial fibrillation with a ventricular rate of 85 per minute. CT brain scan is normal.

What is the most appropriate management?

- 1- amiodarone
- 2- aspirin
- 3- digoxin
- 4- dipyridamole
- 5- warfarin

Answer & Comments

Answer: 5- warfarin

This patient has had three transient ischaemic attacks due to atrial fibrillation. The most appropriate therapeutic strategy for this patient would be warfarin. Studies reveal that warfarin would be therapeutically superior than aspirin in such a patient's case.

[Q: 210] OnExamination - Cardiology

A 65-year-old male is admitted to the coronary care unit with an acute inferior myocardial infarction. There are no contraindications to thrombolysis and he receives streptokinase with good resolution of ECG changes.

Three days later examination is normal, with a blood pressure of 134/76 mmHg. Results

reveal a total cholesterol of 4.8 mmol/L (normal <5.2).

Which one of the following drugs does not have good evidence for reducing future morbidity and mortality?

- 1- Aspirin
- 2- Atenolol
- 3- Simvastatin
- 4- Nifedipine
- 5- Ramipril

Answer & Comments

Answer: 4- Nifedipine

Aspirin leads to a 12% reduced risk of death and 31% reduced risk of reinfarction in evidence reviewed by the Antiplatelet therapy trialists and also GISSI studies. Several trials have demonstrated benefit from long term treatment with beta blockers, by reducing the incidence of recurrent MI, and death from all causes.

Numerous trials have shown benefit from ACE inhibitor therapy post MI in those with and without evidence of left ventricular impairment.

The 4S (Scandinavian Simvastatin Survival Study) demonstrated a benefit from lowering cholesterol with Simvastatin in patients with coronary disease. There is no evidence to support a beneficial effect of nifedipine post MI.

[Q: 211] OnExamination - Cardiology

A 34-year-old male presents with palpitations. The ECG shows a slurred upstroke in the QRS complexes in the chest leads.

What is the treatment of choice?

- 1- Amiodarone
- 2- Aspirin
- 3- Diltiazem

- 4- Radiofrequency ablation
5- Warfarin

Answer & Comments

Answer: 4- Radiofrequency ablation

This patient has Wolff-Parkinson-White syndrome as suggested by the delta wave on ECG. Anticoagulation is not indicated. Risk of arrhythmia after ablation is of the order of 7% over 5 years.

[Q: 212] OnExamination - Cardiology

A 50-year-old man is admitted with cardiogenic shock due to an acute myocardial infarction. His urine output drops over the next few days. His serum urea increases to 18 mmol/L, with creatinine of 300 micromol/L. Urinalysis reveals no protein or glucose, a trace blood, and numerous hyaline casts. Several days later, he develops polyuria and his serum urea and creatinine falls.

Which of the following pathologic findings is most likely to be seen in his kidneys?

- 1- Fusion of podocyte foot processes
- 2- Glomerular crescents
- 3- Hyperplastic arteriosclerosis
- 4- Mesangial immune complex deposition
- 5- Patchy tubular necrosis

Answer & Comments

Answer: 5- Patchy tubular necrosis

He would have findings of ischaemic acute tubular necrosis from cardiogenic shock. Fusion of podocyte foot processes is seen in minimal change glomerulonephritis. Glomerular crescents can complicate any glomerulopathy but, along with mesangial immune complex deposition, is usually an immune-mediated process. Hyperplastic arteriosclerosis is the 'onion skin'

appearance of arterioles in malignant hypertension.

[Q: 213] OnExamination - Cardiology

A 26-year-old professional footballer collapses while playing football. He is rushed to the Accident and Emergency Department, and is found to be in ventricular tachycardia. He is defibrillated successfully and his 12 lead ECG demonstrates normal sinus rhythm, without ST segment changes. Ventricular tachycardia recurs and despite prolonged resuscitation, he dies.

What is the most likely diagnosis?

- 1- Aortic stenosis
- 2- Cocaine intoxication
- 3- Hypertrophic cardiomyopathy
- 4- Myocardial infarction
- 5- Pulmonary embolism

Answer & Comments

Answer: 3- Hypertrophic cardiomyopathy

The history of sudden arrhythmia in a young previously well individual is suggestive of Hypertrophic cardiomyopathy, relatives should be screened for the condition. There is no history to suggest drug abuse, aortic stenosis is rare in the absence of congenital or Rheumatic heart disease. A myocardial infarction and massive pulmonary embolism would have given ECG changes.

[Q: 214] OnExamination - Cardiology

A 40-year-old man attending a routine screening has a blood pressure of 166/100 mmHg. Two weeks later his blood pressure was 150/90 mmHg. He does not smoke. He drinks 35 units alcohol / week. His body mass index (BMI) is 31.5 kg/m² (20 - 25).

What is the best management strategy?

- 1- amlodipine
- 2- atenolol
- 3- bendroflumethiazide
- 4- enalapril
- 5- lifestyle advice

Answer & Comments

Answer: 5- lifestyle advice

This 40-year-old male has Grade 1 obesity as evidenced by his body mass index (Grade 1 = 30-34.9, Grade 2 = 35-39.9 and Grade 3 = > 40). Hypertension in this individual is most likely due to obesity-related hypertension or due to pseudo-cushings syndrome in view of his high alcohol intake and increased BMI. Heightened sympathetic nervous system activity, hyper-insulinemia, insulin resistance, and hyperleptin-emia contribute to obesity-related hypertension.

He needs lifestyle advice about reducing his alcohol intake and a compatible dietary advice to reduce his weight.

[Q: 215] OnExamination - Cardiology

A patient presents with atrial fibrillation and later they revert to sinus rhythm.

Under which of the following circumstances is the patient more likely to remain in sinus rhythm?

- 1- age > 75 years old
- 2- been commenced on warfarin
- 3- left atrium size > 6 cm on ECHO
- 4- short history of AF
- 5- ventricular rate on presentation of 130 bpm

Answer & Comments

Answer: 4- short history of AF

The patient with very recent onset of atrial fibrillation is more likely to stay in sinus rhythm.

Atrial fibrillation in older patients is more likely to be associated with structural heart disease. Anticoagulation should have no effect on the risk of paroxysmal atrial fibrillation. An enlarged left atrium is unlikely to remain in sinus rhythm. Those presenting with a relatively slow ventricular rate and, especially if they are not on betablockers, Calcium antagonists or digoxin, are likely to have chronic atrial fibrillation.

[Q: 216] OnExamination - Cardiology

A 59-year-old male presents with a 1 hour history of central crushing chest pain.. He is known to be diabetic, hypertensive and is a non-smoker. On examination his pulse rate is 90 beats/min, blood pressure 130/85 mmHg, S1 S2 are audible with no murmurs. There is no evidence of cardiac failure. An ECG is performed.

Which of the following would be an indication for thrombolysis?

- 1- Right bundle branch block
- 2- Supraventricular tachycardia
- 3- ST elevation of 2mm in V4-V6
- 4- ST depression of 2mm in leads II,III, avF
- 5- Atrial fibrillation >150min-1

Answer & Comments

Answer: 3- ST elevation of 2mm in V4-V6

This patient is having an acute myocardial infarction, the ECG changes of ST elevation of 2mm in V4-V6 suggest a anterolateral MI. Given this history and ECG changes he should be given thrombolytic treatment. Along with aspirin, heparin, beta blockade, statin therapy and subsequent ACE inhibition. ECG criteria for thrombolysis include ST elevation of >1mm in standard limb leads, ST elevation > 2mm in

anterior chest leads new left bundle branch block, within 24 hours of typical pain. Evidence beyond 12 hours of pain is equivocal thrombolysis at this time tends to be used if there is clinical deterioration or persistent pain.

[Q: 217] OnExamination -
Cardiology

A 50-year-old man with hypertension already on furosemide, ramipril and digoxin is found to poor left ventricular function on echocardiogram.

Which antihypertensive should be added?

- 1- Carvedilol
- 2- Diltiazem
- 3- Doxazosin
- 4- Hydralazine
- 5- Nifedipine

Answer & Comments

Answer: 1- Carvedilol

This patient has hypertension and reduced EF on echo indicating an element of failure. Under these circumstances the most appropriate agent with evidence to support its use for reducing morbidity and mortality in failure would be the addition of a beta blocker.

[Q: 218] OnExamination -
Cardiology

Primary prevention trials for the treatment of hypercholesterolaemia reveal a reduction in all cause mortality following treatment with which of the following?

- 1- Fibrates
- 2- Fish Oils
- 3- Nicotinic acid
- 4- Resins
- 5- Statins

Answer & Comments

Answer: 5- Statins

Primary prevention refers to the prevention of cardiovascular disease in subjects without pre-existent IHD. Although many lipid lowering agents have demonstrated reductions in cardiovascular mortality, the question refers to all cause mortality. WOSCOPS (pravastatin) and AFCAPS-TexCAPS (lovastatin) demonstrated reductions in overall mortality not just cardiovascular mortality following treatment with statins. None of the other agents are proven to reduce all cause mortality in primary prevention. Fibrates are however well proven in secondary prevention trials (BECAIT, VA-HIT).

[Q: 219] OnExamination -
Cardiology

A 17-year-old woman loses consciousness whilst out jogging one afternoon. She has had similar blackouts over the last two to three years which have all occurred during exertion. There is no family history of note. She is taken to Accident and Emergency, where a chest X-ray, CT brain scan, FBC, and biochemistry are all normal. Her ECG shows changes of left ventricular hypertrophy and broad Q waves. An echocardiogram reveals left ventricular and septal hypertrophy, small left ventricle, and reduced septal excursion. The septum has a "ground glass" appearance.

Which of the following conditions is she most likely to have had?

- 1- Diabetes mellitus
- 2- Hypertrophic cardiomyopathy
- 3- Rheumatic heart disease
- 4- Systemic lupus erythematosus
- 5- Viral myocarditis

Answer & Comments

Answer: 2- Hypertrophic cardiomyopathy

The history of collapses in this young woman with echocardiographic features of hypertrophy are highly suggestive of hypertrophic obstructive cardiomyopathy. Hypertrophic cardiomyopathy is defined as the unexplained, asymmetrical or concentric hypertrophy of the undilated left ventricle. There is also hypertrophy of the right ventricle. Incidence is approximately 1 in 500. It is inherited as an autosomal dominant trait but often an inheritance pattern is not found on questioning.

[Q: 220] OnExamination - Cardiology

A 70-year-old woman has a history of dyspnoea and palpitations for six months. An ECG at that time showed atrial fibrillation. She was given digoxin, diuretics and aspirin. She now presents with two short-lived episodes of altered sensation in the left face, left arm and leg. There is poor coordination of the left hand. ECHO was normal as was a CT head scan.

What is the most appropriate next step in management?

- 1- anticoagulation
- 2- carotid endarterectomy
- 3- clopidogrel
- 4- corticosteroid treatment
- 5- no action

Answer & Comments

Answer: 1- anticoagulation

This patient is having symptoms of transient ischaemic attacks most likely due to a cardiac source of emboli. A normal ECHO or CT head does not rule out thrombo-embolic events. There is an increased risk of strokes in patients with atrial fibrillation and hence with the given symptoms formal anticoagulation with warfarin should be considered.

[Q: 221] OnExamination - Cardiology

A 35-year-old lady at 14 weeks gestation is found to have a blood pressure of 160/100 mmHg. Her father's known to have hypertension. Electrocardiogram demonstrates features of left ventricular hypertrophy.

What is the most likely diagnosis?

- 1- Eclampsia
- 2- Essential hypertension
- 3- Pre-eclampsia
- 4- Pregnancy-induced hypertension
- 5- Renal hypertension

Answer & Comments

Answer: 2- Essential hypertension

ECG feature of LVH is the key, telling that her hypertension is not of recent onset, ruling out pregnancy-related causes. Of all causes of hypertension, essential hypertension is the most prevalent. Her family history also supports the diagnosis.

[Q: 222] OnExamination - Cardiology

A 16-year-old male is brought to emergency admissions with alcohol intoxication. An initial ECG reveals atrial fibrillation but a repeat ECG after 12 hours when he has sobered up, shows sinus rhythm. An echocardiogram is normal.

What is the most appropriate management for this patient?

- 1- Aspirin for 3 months
- 2- Bisoprolol for 3 months
- 3- Lifestyle advice
- 4- Sotalol for one month
- 5- Warfarin for one month

Answer & Comments

Answer: 3- Lifestyle advice

Excessive Alcohol is a recognized cause for atrial fibrillation and is the likely cause here as the rhythm has reverted to sinus after 12 hours. There is also no evidence of structural heart disease as the echocardiogram was normal. Therefore this patient needs advice regarding moderation of alcohol consumption and needs to be warned of the toxic effects that alcohol can have on the heart and other organs.

There is no indication for short term aspirin. Atenolol provides rate control, which is not an issue. Sotalol/amiodarone and Flecainide can be used in paroxysmal AF. Short term Warfarin is used for 4-6 weeks prior to elective cardioversion to protect against embolic complications.

[Q: 223] OnExamination - Cardiology

A 60-year-old woman is admitted with sudden onset of chest pain and is diagnosed with an acute myocardial infarction. Her acute illness is complicated by low blood pressure and poor tissue perfusion for several days. Her serum lactate becomes elevated. Her serum urea and creatinine are noted to be increasing.

	Day 1	Day 2	Day 3
urea (mmol/L)	8	22	30
creatinine (mmol/L)	116	140	200

Granular and hyaline casts are present on microscopic urinalysis.

The renal lesion that is most likely to be present in this situation is?

- 1- Acute tubular necrosis
- 2- Minimal change disease
- 3- Nodular glomerulosclerosis
- 4- Pyelonephritis
- 5- Renal vein thrombosis

Answer & Comments

Answer: 1- Acute tubular necrosis

Ischaemia, typically in hypotensive hospitalized patients, is the most frequent antecedent to acute tubular necrosis. Blood pressure should be maintained in cardiogenic shock with fluids and / or inotropic agents.

[Q: 224] OnExamination - Cardiology

A 74-year-old man has had increasingly severe, throbbing headaches for several months, centered on the right. There is a palpable tender cord-like area over his right temple. His heart rate is regular with no murmurs, gallops, or rubs. Pulses are equal and full in all extremities, BP is 110/85 mmHg. A biopsy of this lesion is obtained, and histologic examination reveals a muscular artery with luminal narrowing and medial inflammation with lymphocytes, macrophages, and occasional giant cells. He improves with a course of high-dose corticosteroid therapy.

Which of the following laboratory test findings is most likely to be present with this disease?

- 1- Anti-double stranded DNA titer of 1:1024
- 2- Erythrocyte sedimentation rate of 110 mm/hr
- 3- HDL cholesterol of 0.6 mmol/L
- 4- pANCA titer of 1:160
- 5- Rheumatoid factor titer of 80 IU/mL

Answer & Comments

Answer: 2- Erythrocyte sedimentation rate of 110 mm/hr

These are classic findings for temporal arteritis, the most typical involvement with giant cell arteritis. Corticosteroid therapy typically produces a reduction of symptoms. Not treating this condition puts the patient at risk for involvement of other branches of the external carotid artery, the worst of which would be the ophthalmic branch.

[Q: 225] OnExamination -
Cardiology

A 59-year-old man who was active all his life develops sudden severe anterior chest pain that radiates to his back. Within minutes, he is unconscious. He has a history of hypertension, but a recent treadmill test had revealed no evidence for cardiac disease.

Which of the following is the most likely diagnosis?

- 1- Acute myocardial infarction
- 2- Group A streptococcal infection
- 3- Pulmonary embolus
- 4- Right middle cerebral artery embolus
- 5- Tear in the aortic intima

Answer & Comments

Answer: 5- Tear in the aortic intima

The history is typical of aortic dissection. All the others could cause sudden collapse but not with acute chest pain radiating to the back in the presence of a recent normal exercise test. Acute MI is possible but not the most likely.

[Q: 226] OnExamination -
Cardiology

A 52-year-old male with a five year history of type 2 diabetes is diagnosed with ischaemic heart disease and has recently commenced simvastatin 40mg daily as his cholesterol was 6.2 mmol/l. He re-attends complaining of various muscle aches and pains and you find that his liver function tests are deranged with elevated alkaline phosphatase. You stop the simvastatin and his symptoms subside but his cholesterol remains elevated at 6.3 mmol/l.

Which of the following is the most appropriate strategy to treat his hypercholesterolaemia?

- 1- Bezafibrate
- 2- Ezetimibe

- 3- No treatment required
- 4- Rosuvastatin 10 mg daily
- 5- Simvastatin 20 mg daily

Answer & Comments

Answer: 2- Ezetimibe

This patient has ischaemic heart disease and T2DM and so should be receiving a statin as his cholesterol is also elevated. However, he is intolerant of the statin. Re-introduction of any statin at any dose would have a similar effect and the use of a fibrate may also have a similar side effect profile. Consequently, Ezetimibe would be the most appropriate agent that would be expected to reduce cholesterol concentrations by 25%. It acts to prevent the absorption of cholesterol and is absorbed very little itself so consequently has few side effects.

[Q: 227] OnExamination -
Cardiology

A 52-year-old male attends a well man clinic. On review of his history he has a strong family history of ischaemic heart disease and is a smoker of 10 cigarettes per day and drinks approximately 20 units of alcohol per week. On examination, he is obese with a BMI of 32 kg/m² and has a blood pressure of 152/88 mmHg. His investigations reveal that he has a fasting plasma glucose of 10.5 mmol/l, HbA1c of 7.8% and his cholesterol concentration is 5.5 mmol/l.

Which of the following would be expected to be most effective in reducing his cardiovascular risk?

- 1- Improve glycaemic control with Metformin
- 2- Improve hypertensive control with Ramipril
- 3- Reduce cholesterol with Simvastatin
- 4- Stop smoking
- 5- Weight loss with Xenical

Answer & Comments

Answer: 4- Stop smoking

This patient has hypertension and is diabetic as suggested by the elevated fasting plasma glucose. Although metformin has been shown to reduce CV mortality in obese diabetics (UKPDS), ramipril reduces CV risk in hypertensive diabetics (HOPE) and statins reduce CV mortality (4S, HPS), none of these interventions are as effective as stopping smoking in reducing CV risk. There is no evidence that weight loss per se reduces CV mortality, possibly because the studies haven't been done.

[Q: 228] OnExamination - Cardiology

A 55-year-old male attends for an insurance medical review. He has a family history of ischaemic heart disease and has been feeling tired of late.

Investigations reveal:

Total Cholesterol 6.8 mmol/l

HDL cholesterol 0.9 mmol/l

Triglycerides 2.2 mmol/l

Free Thyroxine 10 mmol/l (9-22)

TSH 22.5 mu/l (0.5-5)

What is the most appropriate treatment for this man's dyslipidaemia?

- 1- Atorvastatin
- 2- Ezetimibe
- 3- Gemfibrozil
- 4- 3-Omega fish oils
- 5- Thyroxine

Answer & Comments

Answer: 5- Thyroxine

This man has subclinical hypothyroidism with a normal T4 but elevated TSH. Thyroid hormone is known to play a role in regulating

the synthesis, metabolism, and mobilization of lipids. It is recognised that the lipid abnormalities tend to resolve following treatment with thyroxine.

[Q: 229] OnExamination - Cardiology

A new antihypertensive drug needs to be investigated to establish its relative potency.

Which of the following techniques is most appropriate for this purpose?

- 1- bioassay
- 2- case-control study
- 3- double-blind, randomized, placebo controlled study
- 4- postmarketing surveillance
- 5- sequential trial

Answer & Comments

Answer: 1- bioassay

Biological assays are designed to measure the relative potency of different preparations. Blood pressure is highly variable and is subject to variability because of the patient's level of anxiety and the method used by the observer to measure it. In a test of EFFICACY of an antihypertensive drug, a double-blind, randomized design would be favourable. A sequential trial (a trial in which the data are analysed after each participant's results become available, and the trial continues until a clear benefit is seen in one of the comparison groups) could also be used to assess efficacy, but there would have to be a large expected difference from placebo.

[Q: 230] OnExamination - Cardiology

A 40-year-old male with type 2 diabetes has difficulty to control hypertension. He is currently being treated with atenolol, amlodipine and Ramipril but his blood

pressure remains consistently above 170/100. Examination reveals grade II hypertensive retinopathy.

His investigations reveal:

Sodium 144 mmol/l

Potassium 3.1 mmol/l

Urea 5.5 mmol/l

Creatinine 100 micromol/l

Glucose 7.9 mmol/l

HbA1c 7%

ECG left ventricular hypertrophy

Which diagnosis should be considered as a cause of his resistant hypertension?

- 1- Conn's syndrome (primary hyperaldosteronism)
- 2- Cushing's syndrome
- 3- Pheochromocytoma
- 4- Primary hyperparathyroidism
- 5- Renal artery stenosis

Answer & Comments

Answer: 1- Conn's syndrome (primary hyperaldosteronism)

This patient has a low potassium concentration and resistant hypertension despite being on an ACEi that should produce an elevation of his potassium concentration. Primary hyperaldosteronism may be due to an adrenal adenoma (Conn's) or bilateral adrenal hyperplasia. The low potassium concentration is highly suggestive. It may be diagnosed based on an elevated renin:aldosterone ratio (usually above 1000).

[Q: 231] OnExamination - Cardiology

A 70-year-old man was referred by his GP with difficult to treat hypertension. He had long-standing hypertension which had been well controlled over many years but recently he

was found to have a blood pressure of 190/110 mmHg which proved resistant to additional treatment. He was generally asymptomatic and complied with medication. Investigations showed normal U+Es.

Which one of the following is the most likely cause?

- 1- Chronic pyelonephritis
- 2- Conn's syndrome (primary hyperaldosteronism)
- 3- Pheochromocytoma
- 4- Polycystic kidney disease
- 5- Renovascular disease

Answer & Comments

Answer: 5- Renovascular disease

Primary hyperaldosteronism (Conn's syndrome) typically have hypokalaemic alkalosis. One should also suspect Conn's with patients resistant to conventional antihypertensive treatment and with the electrolytes in the direction of Conn's without necessarily being outside the normal range (plasma Na > 140 and K < 4).

However, in this patient's case he has long standing hypertension but has deteriorated. Therefore the most likely cause is renovascular disease related to his hypertension.

[Q: 232] OnExamination - Cardiology

A 48-year-old female with a three year history of type 2 diabetes presents at annual review. Despite optimisation of her oral hypoglycaemic therapy she has gained approximately 5 kg in weight over the last year and her HbA1c has deteriorated. She is also treated with Ramipril, Bendroflumethiazide, Amlodipine but her blood pressure remains difficult to control with a recording of 172/102 mmHg. On examination, she has developed abdominal

striae, thin skin is noticeable with bruising and she also has a proximal weakness. A diagnosis of Cushing's syndrome is suspected.

What is the most appropriate investigation for this patient?

- 1- 9 am ACTH concentration
- 2- 9 am cortisol concentration
- 3- 24 hour urine free cortisol concentration
- 4- Chest X-ray
- 5- CT scan adrenals

Answer & Comments

Answer: 3- 24 hour urine free cortisol concentration

Explanation: Appropriate screening tests for Cushing's syndrome include a 1mg overnight dexamethasone suppression test (1mg dexamethasone given at 11pm and the cortisol measured at 9am the following morning). A cortisol concentration less than 50nmol/l after this test would be regarded as normal. Another equally good and easy to perform test is a 24hr urine collection measuring free cortisol in the urine. An elevated cortisol (usually above 250 nmol/day) suggests Cushing's syndrome. Random cortisol or 9am cortisol provides no diagnostic information whatsoever. Chest X-ray and CT adrenals are useful in investigating the possible cause of Cushing's syndrome.

[Q: 233] OnExamination - Cardiology

A 63-year-old male is being reviewed for hypertension associated with type 2 diabetes. Currently he receives aspirin 75mg daily, atenolol 50 mg daily and atorvastatin 20 mg daily. His blood pressure is consistently around 160/92 mmHg.

What antihypertensive therapy would you add to improve this patient's hypertensive control?

- 1- Alpha-methyl dopa

- 2- Bendrofulazide
- 3- Doxazosin
- 4- Moxonidine
- 5- Ramipril

Answer & Comments

Answer: 5- Ramipril

This patient has inadequately controlled hypertension but appears to be tolerating his current therapy well. This chap with T2DM should be on ACE inhibitor, which is the antihypertensive of choice in Diabetes.

[Q: 234] OnExamination - Cardiology

A 24-year-old girl with Down syndrome is found to have a systolic murmur on clinical examination.

What is the most common cardiac defect seen in patients with Down syndrome that may explain this murmur?

- 1- Endocardial cushion defect
- 2- Mitral regurgitation
- 3- Patent ductus arteriosus
- 4- Secundum atrial septal defect
- 5- Ventricular septal defect

Answer & Comments

Answer: 1- Endocardial cushion defect

Endocardial cushion defects, more commonly known as atrioventricular (AV) canal or septal defects, include a range of defects characterized by involvement of the atrial septum, the ventricular septum, and one or both of the AV valves.

[Q: 235] OnExamination - Cardiology

A 65-year-old man has been stable on the general medical ward following an admission

with acute coronary syndrome several days previously. His drug history consists of aspirin, enalapril and GTN spray. He has developed dyspnoea over the last few hours. On examination he has a raised JVP and crackles to his mid zones. His ECG shows a rate of 140 bpm in atrial fibrillation.

Which of the following is the most appropriate management?

- 1- IV amiodarone
- 2- IV digoxin
- 3- IV flecainide
- 4- Observe and screen for MI
- 5- Synchronised DC cardioversion

Answer & Comments

Answer: 5- Synchronised DC cardioversion

It is sometimes difficult to assess if the atrial fibrillation is a cause or a consequence of the heart failure in such a patient but the clinical history suggests that the AF has triggered the symptoms of LVF. The best approach is therefore to quickly to relieve the atrial fibrillation with cardioversion. This may not be possible in which case a pharmacological approach may be tried.

[Q: 236] OnExamination - Cardiology

A 48-year-old man presents with acute coronary syndrome. On examination he has palmar crease xanthoma.

Which of the following is the most likely diagnosis of his lipid abnormalities?

- 1- Familial combined hyperlipidaemia
- 2- Familial hypercholesterolaemia
- 3- Familial hypertriglyceridaemia
- 4- Lipoprotein lipase deficiency
- 5- Remnant hyperlipidaemia

Answer & Comments

Answer: 5- Remnant hyperlipidaemia

Palmar crease xanthoma are associated with remnant hyperlipidaemia (Type III hyperlipidaemia).

[Q: 237] OnExamination - Cardiology

A 50-year-old woman is found to have reversed splitting of the second heart sound.

This is found in which one of the following conditions?

- 1- Atrial septal defect
- 2- Mild aortic regurgitation
- 3- Patent ductus arteriosus
- 4- Right bundle branch block (RBBB)
- 5- Ventricular septal defect (VSD)

Answer & Comments

Answer: 3- Patent ductus arteriosus

Reversed splitting of the 2nd heart sound occurs with reversal of the normal A2,P2 pattern. Thus A2 may be delayed as with severe AS (not mild), and LBBB. P2 may be early as with Wolff-Parkinson-White type B and Persistent Ductus Arteriosus. Atrial septal defects show wide fixed splitting, and RBBB has wide, but not fixed splitting.

[Q: 238] OnExamination - Cardiology

A 45-year-old man presents with a rash. On examination you find he has eruptive xanthoma.

Which of the following is the most likely diagnosis?

- 1- Familial combined hyperlipidaemia
- 2- Familial hypercholesterolaemia
- 3- Familial hypertriglyceridaemia

- 4- Hyperlipidaemia associated with nephrotic syndrome
- 5- Remnant hyperlipidaemia

Answer & Comments

Answer: 3- Familial hypertriglyceridaemia

Eruptive xanthoma occur in a number of types of hypertriglyceridaemia and also in uncontrolled diabetes mellitus. Of those listed the most likely is familial hypertriglyceridaemia.

[Q: 239] OnExamination - Cardiology

A 55-year-old man presented to the Emergency department with sudden breathlessness. He is sweaty and obviously short of breath. He is a smoker with a past history of hypertension. There are crackles on inspiration at both his lung bases and his CXR shows upper lobe venous diversion and perihilar shadowing.

His ECG shows sinus tachycardia only and his cardiac enzymes, when they return the next day, are normal. His symptoms resolved quickly with oxygen and furosemide.

Which of the following conditions is the most likely explanation of this presentation?

- 1- Hypertrophic obstructive cardiomyopathy
- 2- Myocardial infarction
- 3- Pheochromocytoma
- 4- Pulmonary embolism
- 5- Renal artery stenosis

Answer & Comments

Answer: 5- Renal artery stenosis

Flash pulmonary oedema in someone with a history of hypertension, especially those suspected of being arteriopathies such as smokers, should raise the possibility of renal artery stenosis.

[Q: 240] OnExamination - Cardiology

On physical examination a 65-year-old man is found to have pulsus alternans where there is regular alternation of the force of his radial pulse.

Which of the following conditions is the most likely diagnosis?

- 1- Aortic stenosis
- 2- Cardiac tamponade
- 3- Hypertrophic obstructive cardiomyopathy
- 4- Mixed aortic valve disease
- 5- Severe left ventricular failure

Answer & Comments

Answer: 5- Severe left ventricular failure

Pulsus alternans is a physical finding characterized by a regular alternation of the force of the arterial pulse. It almost invariably indicates the presence of severe left ventricular systolic dysfunction.

[Q: 241] OnExamination - Cardiology

A 60-year-old woman has a systolic murmur. As part of the evaluation you listen to the murmur during a Valsalva manoeuvre and the murmur becomes louder.

Which of the following systolic murmurs becomes louder with a Valsalva?

- 1- Aortic stenosis
- 2- Hypertrophic obstructive cardiomyopathy
- 3- Mitral flow murmur
- 4- Mitral regurgitation
- 5- Ventricular septal defect

Answer & Comments

Answer: 2- Hypertrophic obstructive cardiomyopathy

Most murmurs of stenosis or regurgitation are exaggerated during squatting and get softer with the Valsalva manoeuvre. The exceptions are HOCM where the opposite occurs and mitral valve prolapse where the murmur gets longer.

[Q: 242] OnExamination - Cardiology

A 60-year-old man presents with features of left ventricular failure. He is comfortable at rest but ordinary physical activity results in fatigue and shortness of breath.

Which of the following New York Heart Association's classifications best match the severity of this man's disease?

- 1- Normal
- 2- NYHA Class I
- 3- NYHA Class II
- 4- NYHA Class III
- 5- NYHA Class IV

Answer & Comments

Answer: 3- NYHA Class II

In 1928 the New York Heart Association published a classification of patients with cardiac disease based on clinical severity and prognosis. This classification has been updated in seven subsequent editions of Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Great Vessels (Little, Brown & Co.). The ninth edition, revised by the Criteria Committee of the American Heart Association, New York City Affiliate, was released March 4, 1994.

"Class II. Patients with cardiac disease resulting in slight limitation of physical activity. They are comfortable at rest. Ordinary physical activity results in fatigue, palpitation, dyspnea or anginal pain."

[Q: 243] OnExamination - Cardiology

Closure of the tricuspid valve is marked by which of the following features of the jugular venous waveform?

- 1- a wave
- 2- c wave
- 3- v wave
- 4- x descent
- 5- y descent

Answer & Comments

Answer: 2- c wave

The c wave of the jugular venous waveform is associated with the closure of the tricuspid valve.

[Q: 244] OnExamination - Cardiology

A 60-year-old woman with ischaemic heart disease is seen for review. She reports that she has developed symmetrical muscle aches and pains and you attribute this to a myalgia associated with simvastatin. Her Creatinine kinase is within the normal range.

However, her dyslipidaemia management is still sub-optimal and you wish to add in a further agent.

Total Cholesterol 5.5 mmol/L

LDL Cholesterol 3.8 mmol/L

HDL Cholesterol 1.3 mmol/L

Triglycerides 1.4 mmol/L

You plan to continue the statin treatment.

Which of the following agents would be the most appropriate additional therapy for this patient?

- 1- Chloestyramine
- 2- Ezetimibe
- 3- Gemfibrozil

- 4- Nicotinic acid
- 5- Omega-3 fatty acids

Answer & Comments

Answer: 2- Ezetimibe

This patient presents with a probable statin induced myalgia which often improves with time. Sometimes stopping therapy briefly or re-introducing a different statin may resolve the myalgia. Statin induced myositis is relatively uncommon occurring in approximately 0.1-0.2%. But, the risk of myositis and the potentially fatal rhabdomyolysis is increased with Gemfibrozil, in prone subjects in combination with a statin and as such should be avoided. Additional agents could include Omega-3 fatty acids and Ezetimibe. Nicotinic acid is less used due to problems with flushing though can be useful particularly in hypertriglyceridaemia. Cholestyramine can also be used. In this case it is the LDL cholesterol that needs to be targeted and ezetimibe would be the most appropriate choice.

[Q: 245] OnExamination - Cardiology

A 58-year-old man with a history of schizophrenia on thioridazine is found to have episodes of Torsades de Pointes ventricular tachycardia. His blood pressure is 110/70.

Which of the following is the most appropriate management?

- 1- IV betablocker
- 2- IV lidocaine
- 3- IV magnesium
- 4- Overdrive pacing
- 5- Synchronised DC cardioversion

Answer & Comments

Answer: 3- IV magnesium

Thioridazine, an antipsychotic, and many other drugs can prolong the QT interval and increase the risk of Torsade de Pointes VT. Self limiting bursts of Torsade may be seen on an ECG and prompt urgent treatment.

[Q: 246] OnExamination - Cardiology

On physical examination of a 42-year-old man you find a 'jerky' pulse.

Which of the following conditions is most associated with a 'jerky' pulse?

- 1- Aortic stenosis
- 2- Cardiac tamponade
- 3- Hypertrophic obstructive cardiomyopathy
- 4- 'Mixed' aortic valve disease
- 5- Severe left ventricular failure

Answer & Comments

Answer: 3- Hypertrophic obstructive cardiomyopathy

Hypertrophic Obstructive Cardiomyopathy (HOCM) is typically associated with a jerky pulse although it may present with entirely normal clinical findings.

[Q: 247] OnExamination - Cardiology

A 65-year-old man has an ejection systolic murmur and narrow pulse pressure on clinical examination. There is no history of chest pain, breathlessness or syncope. An ECHO confirms aortic stenosis and shows an aortic valve gradient of 40 mmHg. There is good left ventricular function.

Which of the following management options is the most appropriate choice in this case?

- 1- Anticoagulation
- 2- Aortic valvuloplasty
- 3- Cardiology outpatient review
- 4- Routine aortic valve replacement

5- Urgent aortic valve replacement

Answer & Comments

Answer: 3- Cardiology outpatient review

Indications for surgery in aortic stenosis include a gradient of 50 mmHg or more, or associated symptoms such as syncope, breathlessness and episodes of pulmonary oedema. This patient should be monitored in cardiology clinic so that a decision on the timing of valve surgery can be made.

[Q: 248] OnExamination -
Cardiology

On auscultation of a patient's heart you hear a 'pan-systolic murmur'.

With which of the following conditions is this murmur associated?

- 1- Aortic regurgitation
- 2- Coarctation of the aorta
- 3- Mitral stenosis
- 4- Pulmonary stenosis
- 5- Ventricular septal defect

Answer & Comments

Answer: 5- Ventricular septal defect

A pansystolic or holosystolic murmur extends from the 1st heart sound through to the 2nd heart sound which is often hard to hear because of the murmur. It is seen in septal defects and, more commonly, mitral regurgitation.

[Q: 249] OnExamination - Basic Science

Which of the following statement regarding the internal jugular vein and relations is true?

- 1- Originates at the sphenoid sinus
- 2- Lies medial to the common carotid artery
- 3- Passes posterior to the internal carotid artery
- 4- On the right side crosses the first part of the subclavian artery
- 5- The right internal jugular is usually smaller than the left

Answer & Comments

Answer: 4- On the right side crosses the first part of the subclavian artery

The anatomy of the jugular vein is important given that it is the site of insertion of central venous catheters. The internal jugular vein originates at the Jugular foramen. It initially lies posterior and lateral to the carotid artery. As it descends in the carotid sheath it lies lateral first to the internal then the common carotid artery within the carotid sheath. It passes anterior to the subclavian artery to join the subclavian vein to form the innominate vein. The internal jugular vein receives a lymphatic trunk at its union with the subclavian vein. The internal jugular vein is usually of considerable size, and the right internal jugular is usually larger than the left. The external jugular vein drains into the subclavian vein.

[Q: 250] OnExamination - Basic Science

During a neurological examination of the upper limb you attempt to elicit the 'triceps reflex.' You place the patient's arm across the chest, with the elbow flexed at 90°. The triceps tendon is struck with the tendon hammer.

Which nerve (and its nerve root) are you testing?

- 1- Median nerve C6
- 2- Median nerve C7
- 3- Radial nerve C5
- 4- Radial nerve C6
- 5- Radial nerve C7

Answer & Comments

Answer: 5- Radial nerve C7

The radial nerve innervates the triceps muscle, it is primarily derived from the C7 nerve root. The radial nerve is the motor supply to the extensor compartments of the upper limb. The triceps muscle is the chief extensor of the forearm. Its name derives from its three heads of origin (long, lateral and medial). It attaches into the olecranon of the ulna.

[Q: 251] OnExamination - Basic Science

Which of the following organs is in direct contact with the anterior surface of the left kidney, without being separated from it by visceral peritoneum?

- 1- Duodenum
- 2- Jejunum
- 3- Pancreas
- 4- Spleen
- 5- Stomach

Answer & Comments

Answer: 3- Pancreas

The spleen and stomach, though in contact are covered in omentum. The pancreas is retroperitoneal.

[Q: 252] OnExamination - Basic Science

A 35-year-old male is struck on the lateral aspect of his right knee by the bumper of a car travelling at low velocity. On examination he is unable to dorsiflex the ankle, evert the foot

and extend the toes. There is loss of sensation of the dorsum of the foot.

He is most likely to have damaged which structure?

- 1- Common peroneal nerve
- 2- Deep peroneal nerve
- 3- Saphenous nerve
- 4- Sural nerve
- 5- Tibial nerve

Answer & Comments

Answer: 1- Common peroneal nerve

The common peroneal nerve supplies the muscles of the peroneal and anterior compartment of the leg and sensation to the dorsum of the foot. The deep peroneal nerve is a division of the common peroneal nerve and supplies only the muscles of the anterior compartment of the leg.

[Q: 253] OnExamination - Basic Science

Which one of the following biochemical abnormalities would fit with a diagnosis of Bartter's syndrome?

- 1- Hyperchloraemia
- 2- Hyperkalemia
- 3- Hypernatraemia
- 4- Hyperphosphataemia
- 5- Hypokalemia

Answer & Comments

Answer: 5- Hypokalemia

Bartter's syndrome is a condition of excessive renal potassium loss associated with normotension.

[Q: 254] OnExamination - Basic Science

Leukotrienes:

- 1- Are formed from the cyclooxygenase pathway
- 2- Are synthesized by fibroblasts
- 3- Decrease vascular permeability
- 4- Leukotriene D4 has been identified as SRS-A which causes bronchial wall smooth muscle relaxation
- 5- Stimulate mucus secretion

Answer & Comments

Answer: 5- Stimulate mucus secretion

Leukotrienes are synthesized by leucocytes. They are mediators of allergic reaction. They increase vascular permeability and attract neutrophils and eosinophils to inflammatory sites. Leukotrienes are synthesised via the lipoxygenase pathway. Leukotriene D4 has been identified as SRS-A which causes bronchial wall and intestinal smooth muscle contraction (not dilatation). Leukotrienes also stimulate mucus production, an important consideration in the pathophysiology of bronchial asthma.

[Q: 255] OnExamination - Basic Science

A 43-year-old female presents with weight gain and menstrual irregularities. Her BMI is 29 kg/m², blood pressure is 150/90 mmHg and Urinalysis shows + glucose.

Which of the following investigations is most likely to confirm the diagnosis?

- 1- 24 hour urine cortisol
- 2- Aldosterone
- 3- HbA1c
- 4- Prolactin
- 5- Plasma testosterone

Answer & Comments

Answer: 1- 24 hour urine cortisol

The diagnosis here may be Cushing's syndrome. This is supported by the weight gain, high BMI, hypertension, menstrual irregularities and glycosuria. There is a possibility that this vignette describes PCOS, but a single testosterone reading would add little information to the suspected diagnosis. However raised urinary cortisol is a relatively sensitive marker of Cushing's. A random aldosterone level tells you little, and an HbA1c is not an accepted screening tool, even for diabetes. The history does not suggest prolactinoma, which may present with vague symptomatology, galactorrhoea and menstrual irregularities.

[Q: 256] OnExamination - Basic Science

Which of the following is most likely be associated with hyperkalaemia?

- 1- Cushing's syndrome
- 2- Beta adrenergic stimulation
- 3- Mannitol
- 4- Cyclosporin
- 5- Bartter's syndrome

Answer & Comments

Answer: 4- Cyclosporin

Common causes of hyperkalaemia include 1. Impaired renal excretion: renal failure, hyporeninaemic hypoaldosteronism (type IV renal tubular acidosis), Addison's, C-21 hydroxylase deficiency. 2. Cellular changes: acidosis, rhabdomyolysis, tumour lysis, malignant hyperthermia, burns. 3. Drugs: potassium retaining diuretics, ACE inhibitors, NSAIDs, cyclosporin, succinyl choline, β -blockers.

[Q: 257] OnExamination - Basic Science

An Afro-Caribbean male aged 48 years presents with gradual onset of exertional dyspnoea, non productive cough, malaise, weight loss and polyarthralgia. Schirmers test indicates a dry eye. X-ray of the hand shows punched out osteopenic lesions.

Which of the following investigation is unlikely to be helpful in establishing the diagnosis of this condition:

- 1- Serum calcium
- 2- Serum phosphorus
- 3- Urea and electrolytes
- 4- Thallium Scan
- 5- Quantitative Immunoglobulins.

Answer & Comments

Answer: 4- Thallium Scan

This condition is sarcoidosis. Serum calcium, Serum phosphorus, Chem7 and Chem 20 and Quantitative Immunoglobulins are all used in establishing the diagnosis. Gallium scan is helpful in sarcoidosis.

Gallium scan vs. Thallium scan.

Gallium scan (radioactive ^{67}Ga) is used to detect inflammation - such as in inflammatory disorders or malignancy.

Thallium (radioactive ^{201}Tl) is a potassium analogue and is used to demonstrate areas of poor perfusion. It is particularly used in cardiology to detect areas of ischaemia.

[Q: 258] OnExamination - Basic Science

Metabolic alkalosis is characteristically found in which of the following?

- 1- An infusion of sodium chloride
- 2- Ileostomy
- 3- Mineralocorticoid deficiency

4- Pyloric stenosis

5- Salicylate poisoning

Answer & Comments

Answer: 4- Pyloric stenosis

Pyloric stenosis is associated with vomiting and the loss of stomach content ?hence a metabolic alkalosis. Mineralocorticoid excess (Conn's syndrome) is also associated with a metabolic alkalosis. Ileostomy may be associated with a loss of bicarbonate ions and hence acidosis. Salicylates are themselves acidic and produce a metabolic acidosis. Normal saline has a pH of 5 and may produce a mild metabolic acidosis with significant infusions.

[Q: 259] OnExamination - Basic Science

A 65-year-old man with a past history of myocardial infarction 4 years earlier was admitted with sudden onset shortness of breath, decreasing exercise tolerance and pedal oedema. He takes lansoprazole, aspirin, furosemide and lisinopril.

Which of the following laboratory test would identify the reason for his acute presentation?

- 1- Brain natriuretic peptide
- 2- Clotting screen
- 3- C-reactive protein
- 4- Full blood count
- 5- Urea and electrolytes

Answer & Comments

Answer: 1- Brain natriuretic peptide

This patient has features of heart failure which appear to be related to underlying ischaemic heart disease. BNP, is synthesized in the cardiac ventricles and correlates with LV pressure, degree of dyspnoea, and state of neurohormonal modulation. Thus BNP is the

first potential marker for heart failure. Measurement of plasma BNP concentration is evolving as a very efficient and cost effective mass screening technique for identifying patients with various cardiac abnormalities regardless of etiology and degree of LV systolic dysfunction.

[Q: 260] OnExamination - Basic Science

A 75-year-old man presents with a long history of shortness of breath and ankle oedema. His serum biochemistry shows sodium 122 mmols/l and potassium of 2.9 mmols/l. He now complains of weakness.

Which of the following is likely to explain the above biochemical picture?

- 1- Addison's Disease
- 2- Nephrotic syndrome
- 3- Primary hyperaldosteronism
- 4- SIADH
- 5- Diuretic therapy

Answer & Comments

Answer: 5- Diuretic therapy

The long history of his symptoms and serum biochemistry suggests that his condition is due to treatment with furosemide for CCF.

[Q: 261] OnExamination - Basic Science

Lipoprotein lipase deficiency is associated with:

- 1- Abetalipoproteinaemia
- 2- Combined hyperlipidaemia
- 3- Familial combined hyperlipidaemia
- 4- Familial Hypercholesterolaemia
- 5- Marked Hypertriglyceridaemia

Answer & Comments

Answer: 5- Marked Hypertriglyceridaemia

Lipoprotein lipase deficiency is autosomal recessive and associated with increased chylomicrons and marked hypertriglyceridaemia.

[Q: 262] OnExamination - Basic Science

Which of the following stimulate the generation of cyclic AMP as the second messenger?

- 1- Nitric Oxide
- 2- Rosiglitazone
- 3- Tissue Necrosis Factor (TNF) alpha
- 4- Cholera toxin
- 5- Growth hormone

Answer & Comments

Answer: 4- Cholera toxin

Nitric oxide generates cGMP as the second message and rosiglitazone acts through agonism of PPAR gamma. Calcitonin Cholera toxin binds to the Ganglioside receptors and causes excessive production of cAMP which leads to the activation of luminal sodium pumps and the secretory diarrhoea.. GH like TNF alpha acts on the GH/cytokine superfamily of receptor which function via the JAK-STAT pathway.

[Q: 263] OnExamination - Basic Science

Which of the following statements is true concerning gamma glutamyl transferase?

- 1- Increased GGT is found in fatty liver
- 2- Isolated elevation of gamma GT in a patient with prostatic carcinoma Indicates the presence of hepatic metastases.
- 3- It is a better indicator of infectious hepatitis than of cholestasis

4- It is only present in the liver

5- Serum activity is typically elevated in pregnancy

Answer & Comments

Answer: 1- Increased GGT is found in fatty liver

GGT found in muscle, prostate as well as liver. Increased levels of GGT are found in cholestatic liver disease and in hepatocellular disease when there is an element of cholestasis. Levels are increased with chronic intake of excess alcohol and with certain drugs (esp phenytoin), as a result of enzyme induction. Pancreatitis and prostatitis may also be associated with increased levels. Levels may be normal early in the course of acute hepatocellular damage eg acute viral hepatitis, paracetamol hepatotoxicity. Elevations in pregnancy would suggest liver disease.

[Q: 264] OnExamination - Basic Science

A 72-year-old man is found to have the following biochemistry:

calcium 1.98 mmol/l (2.2-2.6)

phosphate 0.55 mmol/l (0.8-1.5)

alkaline phosphatase 450 IU/l (50-110)

Which of the following is the most likely explanation for his biochemistry?

- 1- Osteoporosis
- 2- Osteomalacia
- 3- Pagets Disease
- 4- Tertiary Hyperparathyroidism
- 5- Renal failure

Answer & Comments

Answer: 2- Osteomalacia

Osteomalacia is associated with low calcium and phosphate with raised alkaline phosphatase. Serum biochemistry is normal in osteoporosis. Paget's disease is associated with normal calcium and phosphate with raised alkaline phosphatase. In renal failure when tertiary hyperparathyroidism sets in there is low calcium with raised phosphate. Similarly phosphate tends to be high in secondary hyperparathyroidism.

[Q: 265] OnExamination - Basic Science

A new treatment for osteoarthritis has been developed and shown to be effective in animal models plus its effects in small numbers of patients appears promising. However, there are some concerns with regard to possible hepatotoxicity but no cases have been observed in studies thus far.

Which is the most appropriate next step in this drug's development?

- 1- case control study
- 2- double blind randomised placebo controlled study
- 3- Drug development should be suspended due to the hepatotoxicity
- 4- open label study
- 5- single blind randomised placebo controlled study

Answer & Comments

Answer: 2- double blind randomised placebo controlled study

This drug has completed animal trials and has been tested in human volunteers (phase 1) and has also been tried in patients (phase 2). Thus the next stage in its development is a phase 3 study and the best phase 3 study would be a Randomised control study.

[Q: 266] OnExamination - Basic Science

What is a likely explanation for the high prevalence of cystic fibrosis in European populations?

- 1- Most of the disease genes are hidden in heterozygotes.
- 2- The locus has a high mutation rate.
- 3- Many different mutations can cause cystic fibrosis.
- 4- Inbreeding is common among Europeans.
- 5- Heterozygotes may have an advantage because of increased resistance to cholera.

Answer & Comments

Answer: 5- Heterozygotes may have an advantage because of increased resistance to cholera.

The prevalence of the cystic fibrosis gene at around 1 in 20 of the population would suggest that this provides some evolutionary survival advantage. Like sickle cell trait offering a survival advantage to malaria, it is believed that the cystic fibrosis gene offers a possible survival advantage against cholera and enteropathogenic bacteria.

"Cholera opens chloride channels, letting chloride and water leave cells. The CFTR protein does just the opposite, closing chloride channels and trapping salt and water in cells, which dries out mucus and other secretions. A person with CF cannot contract cholera, because the toxin cannot open the chloride channels in the small intestine.

Carriers of CF enjoy the mixed blessing of a balanced polymorphism. They do not have enough abnormal chloride channels to cause the labored breathing and clogged pancreas of cystic fibrosis, but they do have enough of a defect to prevent the cholera from taking hold. During the devastating cholera epidemics that have peppered history, individuals carrying mutant CF alleles had a

selective advantage, and they disproportionately transmitted those alleles to future generations. However, because CF arose in Western Europe and cholera in Africa, perhaps an initial increase in CF heterozygosity was a response to a different diarrheal infection."

[Q: 267] OnExamination - Basic Science

Which of the following is typically elevated in Gauchers disease?

- 1- Acid phosphatase
- 2- Alkaline phosphatase
- 3- Amylase
- 4- Glucocerebrosidase
- 5- Lipase

Answer & Comments

Answer: 1- Acid phosphatase

Gaucher's disease is the most frequent of the lysosomal storage diseases. The condition is usually due to a catalytic deficiency of glucocerebrosidase. It is accompanied by many ill-understood plasma and metabolic abnormalities. These include a polyclonal immunoglobulin response that may progress to monoclonal gammopathy, amyloidosis, or even frank myeloma. Low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol fractions are abnormal in the plasma. Some lysosomal enzymes are elevated, including tartrate-resistant acid phosphatase, hexosaminidase, and a human chitinase, chitotriosidase. This latter enzyme has proved to be very useful for monitoring Gaucher's disease activity in response to treatment, and may reflect the severity of the disease.

[Q: 268] OnExamination - Basic Science

Where does RNA splicing occur?

- 1- cytoplasm
- 2- endoplasmic reticulum
- 3- mitochondria
- 4- nucleus
- 5- ribosome

Answer & Comments

Answer: 4- nucleus

Coding sequence is interrupted by non-coding sequences. Removal of the introns in RNA transcript modification is called RNA splicing. Splicing occurs in the nucleus before transport to the cytoplasm. Exons are expressed sequences: these sequences are those present in mature mRNA.

[Q: 269] OnExamination - Basic Science

In meiosis which of the following is true?

- 1- DNA replication occurs during meiosis 1.
- 2- At the beginning of meiosis 2, each cell contains 23 single chromosomes.
- 3- Anaphase lag results in one of the 2 daughter cells receiving an extra part of one chromosome.
- 4- Non-disjunction at mitosis (meiosis 2) results in mosaicism.
- 5- The incidence of Down's Syndrome due to translocation increases with increasing maternal age.

Answer & Comments

Answer: 4- Non-disjunction at mitosis (meiosis 2) results in mosaicism.

Meiosis is the form of cell division that produces gametes. It is divided into 2 parts meiosis 1 and meiosis 2. DNA replication occurs before meiosis 1, and the cell begins division with twice the normal cellular amount of DNA.

In meiosis 1, each daughter cell gets one of the duplicated chromosomes of each pair. At the beginning of meiosis 2, each cell contains 23 chromosomes each with a duplicated pair of chromatids.

In meiosis 2, the duplicated pair separate and each daughter cell ends up with one of each of the 23 chromosomes (4 haploid daughter cells). Two common areas of cell division occurring during meiosis are non-disjunction (2 chromosomes fail to separate, so both copies of the chromosome go to one of the daughter cells); and anaphase lag in which a chromatid is lost because it fails to move quickly enough during anaphase to become incorporated into one of the new daughter cells.

In Down's Syndrome, non-disjunction accounts for 94% of cases. The incidence of this increases with increasing maternal age. 5% of cases are due to translocation, and 1% to mosaicism.

[Q: 270] OnExamination - Basic Science

Which of the following is true of autosomal dominant breast cancer?

- 1- It is characterized by loss of heterogeneity
- 2- It accounts for nearly half of all breast cancer cases in the United States
- 3- It can be detected by hybridization with a single oligonucleotide probe
- 4- Penetrance is close to 100%, with nearly all gene carriers developing breast cancer by age 80
- 5- Autosomal dominant breast cancer affects females but not males

Answer & Comments

Answer: 1- It is characterized by loss of heterogeneity

When a cancer of the breast occurs in a member of a high-risk family, the remaining normal copy of the gene is lost through a mutational process called loss of heterozygosity (LOH). The LOH event is a somatic (localized to the breast tissue only) mutation and is not inherited. The result of the two mutational events is that the breast tumor carries one germline mutation and one somatic mutation of BRCA1 or 2. The tumor only grows in the tissue where the second mutation or LOH event occurred. Therefore, the cancer susceptibility gene is what is inherited, not the cancer itself. This means a probability of getting cancer or an increased risk of getting cancer is inherited, not the cancer itself. Therefore, not everyone who is a carrier of a cancer susceptibility gene will get cancer. Additionally, a person who does not carry a particular cancer susceptibility gene is not assured that she or he will not get cancer. Loss of locus heterogeneity characterises autosomal dominant breast cancer which is due to mutations in BRCA1 and BRCA2 (inherited in an autosomal dominant pattern).

[Q: 271] OnExamination - Basic Science

Which of the following is characteristically inherited in an autosomal recessive manner?

- 1- Achondroplasia
- 2- Adult polycystic kidney disease
- 3- C1 esterase deficiency
- 4- Familial hypercholesterolaemia
- 5- Friedreich's ataxia

Answer & Comments

Answer: 5- Friedreich's ataxia

Achondroplasia, APKD, C1 esterase deficiency (hereditary angio-oedema) and familial hypercholesterolaemia are usually inherited as autosomal dominant traits. Friedreich's

ataxia is characteristically an autosomal recessive inheritance.

[Q: 272] OnExamination - Basic Science

A 17-year-old male presented with episodes of low back pain. On clinical examination he is tall and has features of Marfan syndrome. You refer him for echocardiography and he asks why it is needed.

Which of the following is the most common abnormality seen in people with Marfan syndrome?

- 1- Bicuspid aortic valve
- 2- Coarctation of the aorta
- 3- Dilation of the aortic sinuses
- 4- Mitral valve prolapse
- 5- Primum atrial septal defect

Answer & Comments

Answer: 3- Dilation of the aortic sinuses

"The normal aorta has three gentle bulges, the aortic sinuses, just distal to the semilunar attachments of the three leaflets of the aortic valve. The cross sectional diameter of the aorta at the nadir of the leaflet attachment where the aorta and ventricular muscle meet, and at the upper limit of the attachment at the sinutubular junction, are very similar, with the leaflets supported with a spatial relation as if to the sides of a cylinder. The diameter of the more distal circle at the sinutubular junction is, if anything, slightly smaller than the left ventricular outflow. This relation is lost in the Marfan syndrome. The aortic root becomes bulbous and the attachments of the leaflets are splayed out.

[Q: 273] OnExamination - Basic Science

A 16-year-old profoundly deaf boy on holiday in the UK from Denmark presents with

recurrent episodes of syncope and is found to have a long QT interval on his ECG. His faxed medical records indicate that he has Jervell and Lange Nielsen Syndrome.

Which of the following genes is affected in this condition?

- 1- CACNA1c gene
- 2- Caveolin 3 related gene
- 3- Human Ether-a-go-go related gene
- 4- KCNQ1 gene
- 5- SCN5A gene

Answer & Comments

Answer: 4- KCNQ1 gene

Mutations in the KCNE1 and KCNQ1 genes cause Jervell and Lange-Nielsen syndrome. The KCNE1 and KCNQ1 genes provide instructions for making proteins that work together to form a channel across cell membranes. These channels transport positively charged potassium atoms (ions) out of cells. The movement of potassium ions through these channels is critical for maintaining the normal functions of inner ear structures and cardiac muscle. (Read more ...)

All the other genes mentioned are associated with long QT syndromes. The Human Ether-a-go-go Related Gene (HERG) is the gene affected by drugs that lengthen QT interval inadvertently; erythromycin, terfenadine, and ketoconazole. How HERG got its name dates back to Hollywood in the 1960s and involves the fruit fly (*Drosophila*), Whiskey, dancing and a Californian nightclub.

[Q: 274] OnExamination - Basic Science

A 29-year-old male presents to you seeking advice regarding starting a family. He has common variable immunodeficiency and wants to know *what is the risk of passing this on to his children?*

- 1- less than 5%
- 2- 25%
- 3- 33%
- 4- 50%
- 5- over 70%

Answer & Comments

Answer: 1- less than 5%

Common variable immunodeficiency involves low levels of most or all of the immunoglobulin classes, a lack of B lymphocytes or plasma cells that are capable of producing antibodies, and is associated with frequent bacterial infections. The cause of CVID is unknown but a family member may be affected in approximately 20%, but there is no clear pattern of inheritance.

[Q: 275] OnExamination - Basic Science

Which ONE of the following statements regarding X-linked diseases is correct?

- 1- Can occur with equal severity in males and females
- 2- Include G6PD deficiency, ornithine transcarbamylase deficiency, hypophosphataemic rickets and von Willebrands disease
- 3- Do not show anticipation
- 4- Are usually associated with male infertility
- 5- Are not usually associated with immune deficiency

Answer & Comments

Answer: 1- Can occur with equal severity in males and females

X-linked recessive diseases can occur with the same severity in females in certain situations - having an affected father and carrier mother (seen in G6PD deficiency), Turners syndrome, X-chromosome isodisomy, unequal

lyonisation, in an XY individual with testicular feminisation syndrome and where there is an X/autosome translocation through a gene (DMD). Fragile X syndrome shows anticipation with triplet repeat expansion. Y-linked diseases can be associated with male infertility. There are several X-linked immune deficiency syndromes - severe combined immune deficiency, chronic granulomatous disease, agammaglobulinaemia (Bruton's disease), and Wiscott-Aldrich syndrome. Hypophosphataemic rickets is X-linked dominant, and Von Willebrand's disease is inherited in an autosomal dominant manner

[Q: 276] OnExamination - Basic Science

A 35-year-old male presents with oral and genital mucocutaneous ulcerations associated with polyarthritis affecting the lower limbs. He is currently on warfarin for a recent episode of pulmonary embolism.

Which of the genetic association is most commonly associated with his condition:

- 1- HLA A3
- 2- HLA B5
- 3- HLA B27
- 4- HLA DR3
- 5- HLA DR2

Answer & Comments

Answer: 2- HLA B5

This is Behcet's disease. It is associated with increased risk of thrombosis. It is linked to HLA B5.

[Q: 277] OnExamination - Basic Science

Which of the following is a polygenic disorder?

- 1- Ankylosing spondylitis
- 2- Erythropoietic porphyria

- 3- Fragile X syndrome
- 4- Huntington's disease
- 5- Pendred's syndrome

Answer & Comments

Answer: 1- Ankylosing spondylitis

Unlike the other conditions, no one specific genetic defect has been identified to account for ankylosing spondylitis. Huntington's chorea is autosomal dominant condition. Fragile X syndrome is due to a trinucleotide repeat at the FMR 1 gene on the X chromosome. Erythropoietic porphyria is an autosomal recessive condition as is Pendred's syndrome.

[Q: 278] OnExamination - Basic Science

Transcription RNA (tRNA) has three bases specific for a particular amino acid with which it binds to messenger RNA (mRNA).

This specific area of tRNA is called the

- 1- anticodon
- 2- codon
- 3- exon
- 4- intron
- 5- transposon

Answer & Comments

Answer: 1- anticodon

mRNA has codons which are bound by the anticodons on tRNA during translation of protein synthesis. Exons are coding sequences in the mRNA and introns are areas of unknown function. Transposons are genetic sequences that have been transposed from one part of DNA to another.

[Q: 279] OnExamination - Basic Science

With respect to lipoprotein transport and metabolism in the body, the following statements are correct EXCEPT:

- 1- Chylomicrons are synthesized in the liver.
- 2- HDL is assembled in the extracellular space.
- 3- Arterial walls contain cells with LDL receptors.
- 4- VLDL transformation to LDL occurs in the liver.
- 5- Cholesterol is required for the formation of red blood cell membranes.

Answer & Comments

Answer: 1- Chylomicrons are synthesized in the liver.

Chylomicrons are formed in the gut from exogenous triacylglycerols and cholesterol. They are released into the lymph and thereby enter the blood. They are not formed in the liver.

[Q: 280] OnExamination - Basic Science

Which of the following are found in eukaryotic AND prokaryotic cells?

- 1- Chromosomes
- 2- Introns
- 3- Linear DNA
- 4- Nuclear membrane
- 5- Ribosomes

Answer & Comments

Answer: 5- Ribosomes

Eukaryotes (higher organisms) have multiple chromosomes in the genome which is separated from the rest of the cell by nuclear membranes. Prokaryotes lack a membrane bound nucleus, and their DNA occurs in a

circular form. Transcription of eukaryotic genes requires non-coding sequences (introns) in the mRNA to be spliced out before translation at the ribosome. Both Eukaryotes and Prokaryotes have a ribosome, though the ribosome is significantly larger in eukaryotes

[Q: 281] OnExamination - Basic Science

A 17-year-old male who appears tall and thin for his age, presents with a high arch palate, chest wall deformities and livedo reticularis.

Which of the following is also associated with this syndrome?

- 1- Autosomal Dominance
- 2- Methionine accumulation
- 3- Osteopetrosis
- 4- Positive Guthrie test
- 5- Upward dislocation of the lens

Answer & Comments

Answer: 2- Methionine accumulation

This syndrome is most likely to be homocystinuria. Marfan's syndrome is associated with upward dislocation of the lens, but not with livedo reticularis, which is seen in Homocystinuria due to the venous thrombosis in the small vessels of the skin. Homocystinuria is associated with downward dislocation of the lens, and is an Autosomal Recessive disorder. Osteoporosis, and not osteopetrosis is seen in homocystinuria. A positive Guthrie test is associated with Phenylketonuria. Reduced activity of cystathionine α -synthase results in accumulation of homocysteine and methionine, interfering with collagen cross-linking, which is the cardinal feature of Homocystinuria.

[Q: 282] OnExamination - Basic Science

Which one of the following conditions is DNA analysis the most useful diagnostic test?

- 1- Adult polycystic kidney disease
- 2- Down's syndrome
- 3- Huntington's chorea
- 4- Hypertrophic Obstructive Cardiomyopathy
- 5- Klinefelter's syndrome

Answer & Comments

Answer: 3- Huntington's chorea

Klinefelter's syndrome and Down's syndrome are diagnosed principally by chromosomal analysis/karyotype - XXY in the former and trisomy C21 or translocation in the latter. A trinucleotide CAG repeat expansion in the huntingtin gene is diagnostic of Huntington disease. The majority of cases of HOCM are autosomal dominantly inherited yet defective genes are located on a variety of chromosomes. DNA linkage analysis is used to assist in the diagnosis of adult PCKD but the presence of multiple copies continues to complicate the development of reagents for direct genetic testing, at least of the 70% of PKD1 that is replicated elsewhere.

[Q: 283] OnExamination - Basic Science

Mutation in which of the following is associated with Alport's syndrome?

- 1- Collagen type 1 gene
- 2- Collagen type 5 gene
- 3- Fibrillin- gene
- 4- FMR-1 gene
- 5- Type II procollagen gene

Answer & Comments

Answer: 2- Collagen type 5 gene

Mutations in the COL4A5 gene cause approximately 80 percent of Alport syndrome cases. Several hundred different mutations have been identified, the majority of which cause a change in the sequence of amino acids (the building blocks of proteins) in a region of the alpha5(IV) collagen chain that is critical for combining with other type IV collagen chains. Other mutations severely decrease or prevent the production of the alpha5(IV) chains. As a result, there is a serious deficiency of the type IV collagen network in the basement membranes of the kidney, inner ear, and eye

[Q: 284] OnExamination - Basic Science

Which of the following is NOT true regarding the polymerase chain reaction:

- 1- It is used to amplify DNA but not RNA
- 2- The amount of DNA required makes it unsuitable for early prenatal diagnosis
- 3- Synthetic short DNA primers which flank the sequence of interest are required to initiate the amplification
- 4- It utilizes the thermostable properties of Taq DNA polymerase
- 5- It can be used to detect the presence of viral DNA in human disease

Answer & Comments

Answer: 2- The amount of DNA required makes it unsuitable for early prenatal diagnosis

rt-PCR is used to amplify RNA rather than PCR specifically. Preimplantation diagnosis uses IVF and genetic analysis of 3 day old embryos, before selective transfer of unaffected embryos to uterus.

[Q: 285] OnExamination - Basic Science

Which of the following disorders is characterised by an autosomal recessive mode

of inheritance?

- 1- Achondroplasia
- 2- Congenital Adrenal Hyperplasia
- 3- Familial hypercholesterolaemia
- 4- Hereditary Haemorrhagic Telangiectasia
- 5- Huntington's disease

Answer & Comments

Answer: 2- Congenital Adrenal Hyperplasia

All the others are autosomal dominant of course.

[Q: 286] OnExamination - Basic Science

Mutation in which of the following is associated with Ehler-Danlos syndrome?

- 1- Collagen type 1 gene
- 2- Collagen type 5 gene
- 3- Fibrillin- gene
- 4- FMR-1 gene
- 5- Type II procollagen gene

Answer & Comments

Answer: 1- Collagen type 1 gene

The mutations in the COL1A1 gene that cause the arthrochalasia type of Ehlers-Danlos syndrome lead to a pro-alpha1(I) chain that is missing a critical segment. The absence of this segment interferes with the assembly and structure of type I collagen molecules and their processing into collagen fibrils. Tissues that are rich in type I collagen, such as the skin, bones, and tendons, are affected by this change, which leads to the characteristic features of this type of Ehlers-Danlos syndrome.

[Q: 287] OnExamination - Basic Science

Which of the following is true regarding

chromosomes?

- 1- Down's syndrome is most commonly due to an extra copy of chromosome 21 inherited from the father.
- 2- A Fetus with triploidy will have 47 chromosomes
- 3- Heterochromatin is mostly composed of active genes
- 4- The normal human karyotype contains 22 pairs of autosomes
- 5- Telomeres provide the point of attachment to the mitotic spindle

Answer & Comments

Answer: 4- The normal human karyotype contains 22 pairs of autosomes

The human karyotype consists of 22 pairs of autosomes and 1 pair of sex chromosomes. Down's syndrome is most commonly due to trisomy of C21 with the majority a consequence of non-dysjunction within the ovum. Trisomy results in 47 chromosomes whereas Triploidy is the presence of 3 complete sets of chromosomes instead of two in all cells. Heterochromatin is of little genetic significance containing mostly inactivated genes. Telomeres are the distal extremities of the chromosomal arms but the centromeres provide the point of attachment to the mitotic spindle.

[Q: 288] OnExamination - Basic Science

Which of the following conditions is most likely to be detectable by growth monitoring?

- 1- Hyperthyroidism
- 2- Hypothyroidism
- 3- Pseudohypoparathyroidism
- 4- XYY Syndrome
- 5- Insulin dependent diabetes mellitus

Answer & Comments

Answer: 2- Hypothyroidism

Benefits of growth monitoring include:

Early detection of conditions such as:

- " hypothyroidism.
- " growth hormone insufficiency.
- " syndromes: Turners, Russell-Silver, Noonan's, skeletal dysplasias.
- " growth impairment e.g. coeliac disease, inflammatory bowel disease or chronic renal failure.
- " intracranial tumours.
- " short normal children.
- " children with short stature.
- " Health promotion: impaired growth may be associated with child abuse or neglect for example.
- " Focus of interest for parents.

Public health aspects:

- " secular trend of increasing growth.
- " linking growth patterns in fetal life and early infancy with adult patterns of disease.
- " link between height and social circumstances.

[Q: 289] OnExamination - Basic Science

Which molecule is produced in the nucleus, matures in the cytoplasm, binds to the ribosome and initiates protein synthesis?

- 1- messenger RNA
- 2- ribosomal RNA
- 3- RNA nucleotide
- 4- RNA polymerase
- 5- transfer RNA

Answer & Comments

Answer: 1- messenger RNA

Protein synthesis consists of two phases. Transcription is where one strand of the DNA double helix is used as a template by RNA polymerase to synthesize messenger RNA from RNA nucleotides. The mRNA then migrates into the cytoplasm maturing - for example by the splicing of non-coding sequences. Translation occurs when the ribosome binds to mRNA at the start codon and transfer RNA brings amino acids into position along the mRNA template. The ribosome moves from codon to codon along the mRNA producing a polypeptide sequence.

[Q: 290] OnExamination - Basic Science

A 22-year-old female is diagnosed with cystinuria following recurrent episodes of renal colic.

Which of the following is characteristic of cystinuria?

- 1- Autosomal dominant inheritance
- 2- Premature coronary artery disease
- 3- Cataracts
- 4- Cystine deposition within the liver
- 5- Radio-opaque renal calculi

Answer & Comments

Answer: 5- Radio-opaque renal calculi

Cystinuria is an autosomal recessive condition associated with the inadequate reabsorption of cystine (as well as ornithine, arginine, and lysine - Useful mnemonic COAL) in the nephron causing nephrolithiasis - stones are at least partially radio-opaque. It accounts for less than 3% of renal calculi and has an incidence of 1 in 2,500. The foundation of cystine stone prevention is adequate hydration and urinary alkalinization

[Q: 291] OnExamination - Basic Science

Which one of the following conditions is a polygenic disorder?

- 1- Amyotrophic lateral sclerosis
- 2- Congenital adrenal hyperplasia
- 3- Friedreich's ataxia
- 4- Huntington's disease
- 5- Klinefelter's syndrome

Answer & Comments

Answer: 1- Amyotrophic lateral sclerosis

All the other conditions are associated with a specific gene defect -CAH and Friedreich's being autosomal recessive with Huntington's being dominant. Klinefelter's is due to a Chromosomal abnormality XXY. No specific defect has been detected thus far with ALS.

[Q: 292] OnExamination - Basic Science

Restriction enzymes:

- 1- Cut DNA
- 2- Join two pieces of DNA together
- 3- Synthesize DNA
- 4- Degrade DNA
- 5- Are involved in cell cycle arrest

Answer & Comments

Answer: 1- Cut DNA

Restriction enzymes cut DNA at sequences specific for each restriction enzyme, they are vital tools for molecular biology and molecular genetic research.

[Q: 293] OnExamination - Basic Science

The level of cellular telomerase activity will affect:

- 1- The rate of cell growth
- 2- Cell death
- 3- The number of cell divisions a cell is capable of undergoing
- 4- Cell survival
- 5- RNA synthesis

Answer & Comments

Answer: 3- The number of cell divisions a cell is capable of undergoing

The telomere is a DNA sequence at the end of each chromosome which becomes progressively shorter with each division the cell undergoes. When it is reduced to a critical length the cell is not capable of dividing, the enzyme telomerase is able to lengthen the telomere thus preventing this occurring.

[Q: 294] OnExamination - Basic Science

The Polymerase Chain Reaction (PCR) is used to amplify small amounts of DNA for further analysis. First the DNA double helix must be split into two strands.

This is achieved by

- 1- alkali solution
- 2- centrifugation
- 3- DNA polymerase
- 4- heating to nearly 100°C
- 5- viral reverse transcriptase

Answer & Comments

Answer: 4- heating to nearly 100°C

To the small sample of DNA are added two oligonucleotides with sequences that have affinity for both ends of the area of DNA that is being studied. A thermostable DNA polymerase is also added. At 94°C DNA literally melts into two single strands and with cooling the oligonucleotides bind to the areas

surrounding the particular area of DNA that is being analysed. These act as primers for the DNA polymerase and a new double helix of DNA is formed. The cycle is repeated doubling the amount of DNA each time.

[Q: 295] OnExamination - Basic Science

Which of the following disorders is characterised by an autosomal dominant mode of inheritance?

- 1- Beta-thalassaemia
- 2- Cystic fibrosis
- 3- Marfan syndrome
- 4- Wilson's disease
- 5- Xeroderma Pigmentosa

Answer & Comments

Answer: 3- Marfan syndrome

All the others are autosomal recessive of course.

[Q: 296] OnExamination - Basic Science

Parents of a 6-year-old boy present concerned that their son may be carrying the gene for Huntingtons disease. The father was diagnosed with the disease at age 32. The mother has been genetically screened and is not a carrier of the gene.

What the likelihood is of their son suffering with Huntingtons disease?

- 1- 0 risk
- 2- 1 in 2
- 3- 1 in 4
- 4- 1 in 8
- 5- 3 in 4

Answer & Comments

Answer: 2- 1 in 2

Huntington's disease (HD), a progressive, degenerative neurological disease, has an autosomal dominant mode of transmission. This means that only one copy of the faulty gene is required in the genotype for the patients to be a sufferer. With the above case the father is heterozygous which means he himself only has one copy of the gene (two copies of the gene are very unlikely with extremely severe phenotypes probably incompatible with life) and the mother seems to have no copies of the gene. In this case with an autosomal dominant disease, the likelihood of a child developing the disease is 1 in 2 as it is expected that 50% of the offspring of this couple will have a faulty gene.

Symptoms of this disease tend to start to develop in early middle age and include an unsteady gait and jerky involuntary movements, accompanied later by behavioural changes and progressive dementia. The defective gene is located on chromosome 4. Genetic screening is now available

[Q: 297] OnExamination - Basic Science

Restriction enzymes:

- 1- Cut DNA
- 2- Join two pieces of DNA together
- 3- Synthesize DNA
- 4- Degrade DNA
- 5- Are involved in cell cycle arrest

Answer & Comments

Answer: 1- Cut DNA

Restriction enzymes cut DNA at sequences specific for each restriction enzyme, they are vital tools for molecular biology and molecular genetic research.

[Q: 298] OnExamination - Basic Science

The Polymerase Chain Reaction (PCR) is used to amplify small amounts of DNA for further analysis. First the DNA double helix must be split into two strands.

This is achieved by

- 1- alkali solution
- 2- centrifugation
- 3- DNA polymerase
- 4- heating to nearly 100°C
- 5- viral reverse transcriptase

Answer & Comments

Answer: 4- heating to nearly 100°C

To the small sample of DNA are added two oligonucleotides with sequences that have affinity for both ends of the area of DNA that is being studied. A thermostable DNA polymerase is also added. At 94°C DNA literally melts into two single strands and with cooling the oligonucleotides bind to the areas surrounding the particular area of DNA that is being analysed. These act as primers for the DNA polymerase and a new double helix of DNA is formed. The cycle is repeated doubling the amount of DNA each time.

[Q: 299] OnExamination - Basic Science

Which one of the following conditions is a polygenic disorder?

- 1- Amyotrophic lateral sclerosis
- 2- Congenital adrenal hyperplasia
- 3- Friedreich's ataxia
- 4- Huntington's disease
- 5- Klinefelter's syndrome

Answer & Comments

Answer: 1- Amyotrophic lateral sclerosis

All the other conditions are associated with a specific gene defect -CAH and Friedreich's being autosomal recessive with Huntington's being dominant. Klinefelter's is due to a Chromosomal abnormality XXY. No specific defect has been detected thus far with ALS.

[Q: 300] OnExamination - Basic Science

Which molecule is produced in the nucleus, matures in the cytoplasm, binds to the ribosome and initiates protein synthesis?

- 1- messenger RNA
- 2- ribosomal RNA
- 3- RNA nucleotide
- 4- RNA polymerase
- 5- transfer RNA

Answer & Comments

Answer: 1- messenger RNA

Protein synthesis consists of two phases. Transcription is where one strand of the DNA double helix is used as a template by RNA polymerase to synthesize messenger RNA from RNA nucleotides. The mRNA then migrates into the cytoplasm maturing - for example by the splicing of non-coding sequences. Translation occurs when the ribosome binds to mRNA at the start codon and transfer RNA brings amino acids into position along the mRNA template. The ribosome moves from codon to codon along the mRNA producing a polypeptide sequence.

[Q: 301] OnExamination - Basic Science

Which of the following is true regarding chromosomes?

- 1- Down's syndrome is most commonly due to an extra copy of chromosome 21 inherited from the father.

- 2- A Fetus with triploidy will have 47 chromosomes
- 3- Heterochromatin is mostly composed of active genes
- 4- The normal human karyotype contains 22 pairs of autosomes
- 5- Telomeres provide the point of attachment to the mitotic spindle

Answer & Comments

Answer: 4- The normal human karyotype contains 22 pairs of autosomes

The human karyotype consists of 22 pairs of autosomes and 1 pair of sex chromosomes. Down's syndrome is most commonly due to trisomy of C21 with the majority a consequence of non-dysjunction within the ovum. Trisomy results in 47 chromosomes whereas Triploidy is the presence of 3 complete sets of chromosomes instead of two in all cells. Heterochromatin is of little genetic significance containing mostly inactivated genes. Telomeres are the distal extremities of the chromosomal arms but the centromeres provide the point of attachment to the mitotic spindle.

[Q: 302] OnExamination - Basic Science

Which of the following disorders is characterised by an autosomal dominant mode of inheritance?

- 1- Beta-thalassaemia
- 2- Cystic fibrosis
- 3- Marfan syndrome
- 4- Wilson's disease
- 5- Xeroderma Pigmentosa

Answer & Comments

Answer: 3- Marfan syndrome

All the others are autosomal recessive of course.

[Q: 303] OnExamination - Basic Science

The level of cellular telomerase activity will affect:

- 1- The rate of cell growth
- 2- Cell death
- 3- The number of cell divisions a cell is capable of undergoing
- 4- Cell survival
- 5- RNA synthesis

Answer & Comments

Answer: 3- The number of cell divisions a cell is capable of undergoing

The telomere is a DNA sequence at the end of each chromosome which becomes progressively shorter with each division the cell undergoes. When it is reduced to a critical length the cell is not capable of dividing, the enzyme telomerase is able to lengthen the telomere thus preventing this occurring.

[Q: 304] OnExamination - Basic Science

A 22-year-old female is diagnosed with cystinuria following recurrent episodes of renal colic.

Which of the following is characteristic of cystinuria?

- 1- Autosomal dominant inheritance
- 2- Premature coronary artery disease
- 3- Cataracts
- 4- Cystine deposition within the liver
- 5- Radio-opaque renal calculi

Answer & Comments

Answer: 5- Radio-opaque renal calculi

Cystinuria is an autosomal recessive condition associated with the inadequate reabsorption of cystine (as well as ornithine, arginine, and lysine - Useful mnemonic COAL) in the nephron causing nephrolithiasis - stones are at least partially radio-opaque. It accounts for less than 3% of renal calculi and has an incidence of 1 in 2,500. The foundation of cystine stone prevention is adequate hydration and urinary alkalinization

[Q: 305] OnExamination - Basic Science

Transcription RNA (tRNA) has three bases specific for a particular amino acid with which it binds to messenger RNA (mRNA).

This specific area of tRNA is called the

- 1- anticodon
- 2- codon
- 3- exon
- 4- intron
- 5- transposon

Answer & Comments

Answer: 1- anticodon

mRNA has codons which are bound by the anticodons on tRNA during translation of protein synthesis. Exons are coding sequences in the mRNA and introns are areas of unknown function. Transposons are genetic sequences that have been transposed from one part of DNA to another.

[Q: 306] OnExamination - Basic Science

Which ONE of the following have their own self replicating DNA?

- 1- Golgi body
- 2- Lysosomes
- 3- mitochondria
- 4- Peroxisome

5- Rough Endoplasmic Reticulum

Answer & Comments

Answer: 3- mitochondria

Abnormalities of Mitochondrial DNA are associated with inherited conditions such as Leber's OA, MELAS syndrome and DIDMOAD (Dr Vajira H. W. Dissanayake)

[Q: 307] OnExamination - Basic Science

A Plasmid is best described as

- 1- a recombinant section of DNA
- 2- a small viral particle
- 3- bacterial DNA separate from the chromosome
- 4- consist of multiple copies of a single gene
- 5- having multiple origins of replication [25]

Answer & Comments

Answer: 3- bacterial DNA separate from the chromosome

Plasmids are circular molecules of bacterial DNA separate from the bacterial chromosome. They are usually small consisting of a few thousand base pairs, carry one or a few genes, and have a single origin of replication. Genes on plasmids with multiple copies are usually expressed at higher levels. In nature these genes often encode for proteins such as those needed for bacterial resistance. Plasmids can be used to clone genes by splicing a particular gene into a plasmid and then allowing the bacteria to multiply - this is then called recombinant plasmid DNA.

[Q: 308] OnExamination - Basic Science

A 28-year-old lady presents with multiple café-au-lait spots. A diagnosis of

neurofibromatosis type 1 is made.

What is true of the NF1 gene?

- 1- Inherited in a recessive fashion
- 2- Inherited in an X-linked fashion
- 3- On chromosome 17
- 4- On mitochondrial genome
- 5- Related to NF2 gene

Answer & Comments

Answer: 3- On chromosome 17

Neurofibromatosis due to NF1 is found on chromosome 17 and is inherited as an autosomal dominant fashion. NF2 is associated with acoustic neuromas and is found on Chromosome 22.

[Q: 309] OnExamination - Basic Science

Mutation in which of the following is associated with Marfan's syndrome?

- 1- Collagen type 1 gene
- 2- Collagen type 5 gene
- 3- Fibrillin- gene
- 4- FMR-1 gene
- 5- Type II procollagen gene

Answer & Comments

Answer: 3- Fibrillin- gene

Mutation in the fibrillin-1 gene is felt to be responsible for Marfan's syndrome. In marfan syndrome the lack of normal fibrillin-1 leads to overactivity of TGF- β in the wall of the aorta and the heart valves, leading to damage and destruction to the connective tissue which weakens that aortic wall and heart valves, causing them to stretch. Type 1 collagen gene defects are found in osteogenesis imperfecta and type 3 in Ehler's Danlos syndrome. Type II procollagen defect is found in hereditary spodyloarthopathy.

[Q: 310] OnExamination - Basic Science

It has been suggested that cystic fibrosis (autosomal recessive) has a high prevalence in some populations because heterozygotes are resistant to the effects of chloride-secreting diarrhea.

This is best described as an example of

- 1- Mutation
- 2- Gene flow
- 3- Genetic drift
- 4- Natural selection
- 5- Linkage disequilibrium

Answer & Comments

Answer: 4- Natural selection

Natural selection is the likely explanation as it appears that heterozygous for CF may offer some protection against diarrhoeal illnesses particularly typhoid.

[Q: 311] OnExamination - Basic Science

Which of the following abnormalities is associated with short stature?

- 1- 45, XO karyotype
- 2- 47, XXY karyotype
- 3- 47 XYY karyotype
- 4- fragile X syndrome
- 5- homocystinuria

Answer & Comments

Answer: 1- 45, XO karyotype

Turner's syndrome, 45 XO is characteristically associated with short stature. Klinefelter's is associated with tall stature. In Fragile X, height is usually unaffected and Homocystinuria may have a Marfan's habitus.

[Q: 312] OnExamination - Basic Science

A 17-year-old female is affected by an inherited disorder. She has two brothers who are unaffected. She has two sisters both are affected. Her father is affected but not her mother.

What is the mode of inheritance?

- 1- Autosomal Dominant [50]
- 2- Autosomal Recessive
- 3- Mitochondrial
- 4- X-linked Dominant
- 5- X-linked Recessive

Answer & Comments

Answer: 4- X-linked Dominant

X-linked dominant disorders are rare (e.g. Vitamin D-resistant rickets). The affect both sexes but females more than males. All children of a homozygous mother are affected. Half the sons and half the daughters inherit the disorder from an affected mother with the trait. An affected father passes the disease to all his daughters but none of his sons - as in this example. Another explanation would be an autosomal dominant disorder inherited, by chance, only by the daughters. However, this is not the best answer.

[Q: 313] OnExamination - Basic Science

Benign Essential Tremor:

- 1- Is present characteristically at rest
- 2- Occur with lesion in sub thalamus
- 3- Occur in liver disease
- 4- Alcohol improves the tremor
- 5- Is autosomal recessive in inheritance

Answer & Comments

Answer: 4- Alcohol improves the tremor

There is no tremor at rest, but a rhythmic oscillation develops when the patient holds the arms outstretched. A positive family history is obtained in over half of such patients and the pattern of inheritance in such families indicates an autosomal dominant trait. Alcohol suppresses essential tremor, but the mechanism responsible is unknown

[Q: 314] OnExamination - Basic Science

You would be likely to observe the lowest heritability score in

- 1- Cystic fibrosis
- 2- Spina bifida
- 3- Cleft lip/palate
- 4- Mumps
- 5- Congenital heart disease

Answer & Comments

Answer: 4- Mumps

Mumps is due to an infective agent and hence has the lowest heritability score. All the other disorders have a genetic aetiological component eg CF autosomal recessive.

[Q: 315] OnExamination - Basic Science

In X-linked recessive inheritance, which of the following is true?

- 1- The male to female ratio is 2:1.
- 2- Each son of a female carrier has a 1:4 risk of being affected.
- 3- Each daughter of a female carrier has a 1:4 risk of being a carrier.
- 4- Daughters of affected males will all be carriers.
- 5- The family history is often positive since new mutations are rare.

Answer & Comments

Answer: 4- Daughters of affected males will all be carriers.

Over 250 X-linked recessive disorders have been described. The commonest include red/green colour blindness, Duchenne and Becker muscular dystrophies, Fragile X Syndrome, G6PD deficiency, haemophilias A&B, and Hunter's Syndrome. The abnormal gene is carried on the X chromosome, and in the carrier female, the normal allele on her other X chromosome protects her from the disease. Since the male does not have this protection, he manifests the disease. In X-linked inheritance therefore:

- " Males are all affected.
- " Females only occasionally show mild sign of disease.
- " Each son of a female carrier has a 1:2 chance of being affected.
- " Each daughter of a female carrier has a 1:2 risk of being a carrier.
- " Daughters of affected males will all be carriers, but sons of affected males will not be affected since the Y chromosome is derived from father.

The family history may be negative, however, since new mutations are fairly common. Carrier females can be identified from time to time from mild clinical manifestations and from specific tests such as biochemical markers, e.g. CK in DMD.

[Q: 316] OnExamination - Basic Science

A 59-year-old woman has had insulin dependent diabetes mellitus for over two decades. The degree of control of her disease is characterized by the laboratory finding of a HbA1c of 10.1%. She complains of repeated episodes of abdominal pain following meals. These episodes have become more frequent

and last for longer periods over the last couple of months. On physical examination, there are no abdominal masses and no organomegaly of the abdomen, and she has no tenderness to palpation.

Which of the following findings is most likely to be present:

- 1- Ruptured aortic aneurysm
- 2- Hepatic infarction
- 3- Mesenteric artery occlusion
- 4- Acute pancreatitis
- 5- Chronic renal failure

Answer & Comments

Answer: 3- Mesenteric artery occlusion

Diabetes- especially Type 2 diabetes- is associated with macrovascular disease. Smoking is a further risk factor for macrovascular atherosclerosis. After a meal splanchnic blood flow is increased. If the mesenteric artery is occluded the lack of blood flow to the bowel will produce ischaemic type pain. Chronic renal failure may be present but would not cause post prandial pain. Ruptured aortic aneurysm would normally present acutely with hypotension, cold lower limbs with reduced pulses and a pulsatile, tender abdominal mass. Pancreatitis is unlikely given the history and the lack of epigastric tenderness. Hepatic infarction should lead to right upper quadrant pain.

[Q: 317] OnExamination - Basic Science

Regarding the genetics of bronchial asthma

- 1- Mendelian recessive inheritance
- 2- Leukotriene concentrations are influenced by genetic factors
- 3- Similar concordance in monozygotic and dizygotic twins
- 4- Genetic linkage is to a single chromosome 13

- 5- There is a contribution from HLA alleles

Answer & Comments

Answer: 5- There is a contribution from HLA alleles

There may be genetic linkage of atopic trait to chromosome 11, with association between response to antigen and HLA haplotype. IgE concentrations are influenced by genetic factors.

[Q: 318] OnExamination - Basic Science

A 65-year-old man has IgG paraproteinaemia with plasma cells in his bone marrow aspirate.

Which of the following is most likely with his underlying condition?

- 1- Renal failure is the commonest cause of death
- 2- Sclerotic bone lesions are characteristic
- 3- Biphosphonates are first line therapy for the treatment of associated hypercalcaemia
- 4- Treatment with interferon alpha improves survival
- 5- bone resorption is due to increased osteoblast activity

Answer & Comments

Answer: 4- Treatment with interferon alpha improves survival

Infection is the commonest cause of death in multiple myeloma because of immunoparesis. Lytic bone lesions commonly occur due to increased osteoclastic activity, rarely sclerotic lesions occur. Vigorous hydration and diuresis are cornerstones of the treatment of severe hypercalcaemia in myeloma. Interferon alpha is the only agent found to prolong plateau phase of disease (used in maintenance therapy).

[Q: 319] OnExamination - Basic Science

In idiopathic thrombocytopaenic purpura there antibodies directed at which of the following?

- 1- ADP receptor
- 2- Antithrombin III
- 3- ATP receptor
- 4- Glycoprotein IIb/IIIa complex
- 5- Platelet-activating factor

Answer & Comments

Answer: 4- Glycoprotein IIb/IIIa complex

In many cases of idiopathic thrombocytopaenic purpura, the cause is not actually idiopathic but autoimmune, with antibodies against platelets being detected in approximately 80% of patients. Most often these antibodies are against platelet membrane glycoproteins IIb-IIIa or Ib-IX, and are of the IgG type. The coating of platelets with IgG renders them susceptible to opsonization and phagocytosis by splenic macrophages.

[Q: 320] OnExamination - Basic Science

Which one of the following statements regarding T cells in their recognition of antigen is correct:

- 1- By TcR interaction with antigen in the extracellular fluid.
- 2- As conformational epitope at the cell surface.
- 3- As linear peptide sequences bound covalently to self MHC class I or class II at the cell surface.
- 4- Derived from protein only
- 5- Only when presented by "professional" antigen presenting cells.

Answer & Comments

Answer: 4- Derived from protein only

TCR's interact with a complex of antigenic peptide bound to MHC molecules and presented at the cell surface of the antigen presenting cell. T cells recognise antigen as linear peptide epitopes associated with self MHC molecules. Peptides associate non-covalently with MHC class I or class II molecules at the cell surface. T cells recognise peptides, therefore T cell antigens are derived from proteins, but not from carbohydrate or lipid molecules. 'Professional' antigen presenting cells are required for the induction phase of the T cell response, but activated effector T cells can recognise antigen presented by MHC molecules on a wide range of cell types (for example, CTL recognition of virally infected target cells). (c) Dr Alan Cann

[Q: 321] OnExamination - Basic Science

Which one of the following is correct concerning Mast cells?

- 1- Do not contain heparin
- 2- Degranulation releases lytic enzymes and inflammatory mediators from storage granules
- 3- Are lipophilic cells involved in inflammatory and immune responses
- 4- Cross-linkage of surface IgA molecules by antigen may cause an anaphylactic reaction
- 5- Depletion of circulating mast cells can cause mastocytosis

Answer & Comments

Answer: 2- Degranulation releases lytic enzymes and inflammatory mediators from storage granules

Mast cells are basophilic cells in the connective and subcutaneous tissues, which

are involved in inflammatory and immune responses. They contain storage granules that contain lytic enzymes (e.g. tryptase) and inflammatory mediators, e.g. histamine, heparin, 5-HT, leukotrienes, platelet aggregating factor, leucocyte chemotactic factor and hyaluronidase. Release of these mediators occurs during mast cell degranulation, which can be triggered by: tissue injury, drugs, complement activation, and foreign antigenic material. An anaphylactic reaction occurs when a previously sensitised individual is re-exposed to the antigen. It is an IgE mediated immune response. Mastocytosis occurs when excess mast cells are present in the circulation or as tissue infiltrates.

[Q: 322] OnExamination - Basic Science

Which of the following statements is true of Xenotransplantation?

- 1- is the transfer of organs between species
- 2- is the transfer of tissue grown in-vitro
- 3- has not yet been performed in humans
- 4- requires a close HLA match
- 5- is characterised by a vigorous early cell - mediated immune response

Answer & Comments

Answer: 1- is the transfer of organs between species

Xenotransplantation is the transfer of organs between species - particularly the transfer of animal organs to humans. Compare this with allotransplantation which is the transfer of organs within the same species.

There have already been several documented cases of xenotransplantation - baboon heart, chimpanzee kidneys. A close HLA match is not possible of course unless a transgenic species is used that express human major

histocompatibility complexes (HLA). Early immune response is humoral - IgM.

[Q: 323] OnExamination - Basic Science

A 50-year-old African American woman presents with episodic toe and finger problems characterized by pallor, cyanosis, suffusion and pain of the fingers and toes in response to cold. She later develops difficulty in swallowing and dyspnoea.

Which of the following immunological investigations is the most specific for this lady's condition:

- 1- Topoisomerase I
- 2- Anticentromere antibody
- 3- Antitopoisomerase I (Scl-70) antibody
- 4- Rheumatoid factor
- 5- Anti-ds DNA antibody

Answer & Comments

Answer: 3- Antitopoisomerase I (Scl-70) antibody

This lady has systemic sclerosis as suggested by the dyspnoea (lung fibrosis, dysphagia (oesophageal involvement) and Raynaud's. The lung involvement would argue against this being CREST and hence positive anticentromere antibodies. . SCL-70 antigen (topoisomerase I) is a DNA-binding protein sensitive to nucleases and is typically found in progressive systemic sclerosis.

[Q: 324] OnExamination - Basic Science

Which of the following statements concerning the thymus is true?

- 1- The majority of cortical thymocytes express either CD4 or CD8.
- 2- CD4/CD8 double positive cells are eliminated by a process of negative selection.

- 3- A proportion of alpha/beta+ thymocytes undergo isotype switching to produce gamma/delta+ T cells.
- 4- Thymocytes whose TcR bind with high affinity to self Ag/MHC complexes are clonally deleted.
- 5- Mature thymocytes express surface IgM and IgD.

Answer & Comments

Answer: 4- Thymocytes whose TcR bind with high affinity to self Ag/MHC complexes are clonally deleted.

Cortical thymocytes are immature forms, and either do not express CD4 or CD8 (double negative cells) or express both CD4 and CD8 (double positive cells). As the cells mature, they pass to the thymic medulla, where they lose expression of either CD4 or CD8, to become single positive cells.

Negative selection occurs at the stage when thymocytes express both CD4 and CD8, but co-expression of these markers does not mediate negative selection. Negative selection occurs when a thymocyte expresses a TcR with high affinity for self antigen:MHC complexes in the thymic micro-environment.

Once a thymocyte has successfully rearranged and expressed an alpha/beta or gamma/delta TcR it is committed to that lineage.

Thymocytes whose TcR bind with high affinity to self Ag/MHC complexes are clonally deleted by a process of negative selection.

B cells express IgM and IgD; T cells do not!

[Q: 325] OnExamination - Basic Science

A 16-year-old female develops an urticarial reaction and is suspected of peanut allergy yet measurement of peanut-specific IgE antibodies on RAST testing is within the normal range.

Which of the following would be the next most appropriate investigation?

- 1- C1 esterase concentrations
- 2- No other test necessary diagnosis can be secured on history
- 3- Food provocation testing
- 4- Mast cell degranulation testing
- 5- Skin prick testing

Answer & Comments

Answer: 5- Skin prick testing

The most appropriate next test would be skin allergen testing as a food provocation test is often unnecessary and can prove rather dangerous although is the gold standard.

[Q: 326] OnExamination - Basic Science

Deficiency of T-cells is found in

- 1- Wiscott-Aldrich syndrome
- 2- hereditary angio-oedema
- 3- chronic granulomatous disease
- 4- Chediak-Higashi syndrome
- 5- congenital agammaglobulinaemia

Answer & Comments

Answer: 1- Wiscott-Aldrich syndrome

congenital agammaglobulinaemia = antibody deficiency (X-linked) hereditary angio-oedema = C1 esterase deficiency (autosomal dominant) chronic granulomatous disease = disorder of oxidative mechanism - susceptible to pyogenic/fungal infections. Deficiency of T-cells is found in also found in ataxia telangiectasia. Chediak-Higashi syndrome is autosomal recessive and is characterized by defective fusion with the phagosome in phagocytes.

[Q: 327] OnExamination - Basic Science

Which of the following cell types have a prime role in recognizing and destroying virus infected cells in an HLA class I-restricted manner.

- 1- Macrophages
- 2- B cells
- 3- Dendritic cells
- 4- Platelets
- 5- CD8+ T lymphocytes

Answer & Comments

Answer: 5- CD8+ T lymphocytes

CD8+ T lymphocytes are otherwise known as cytotoxic T lymphocytes. The T cell receptor on the surface of the CD8+ T cell recognizes virus peptides in the context of self HLA class I molecules on the surface of virus infected antigen presenting cells. The infected cell is then lysed. Dendritic cells are professional antigen presenting cells presenting antigen to CD4+ helper cells and CD8+ T cells, but have no cytotoxic potential. B cells produce antibodies. Macrophages are also antigen presenting cells but are also involved in recognition and eradication of certain intracellular pathogens but in a non-HLA restricted manner.

[Q: 328] OnExamination - Basic Science

The Mantoux reaction is an example of which type of hypersensitivity reaction ?

- 1- Type I hypersensitivity
- 2- Type II hypersensitivity
- 3- Type III hypersensitivity
- 4- Type IV hypersensitivity
- 5- Humoral Immune Response

Answer & Comments

Answer: 4- Type IV hypersensitivity

The tuberculin skin test is an example of a Type IV hypersensitivity, or a delayed type hypersensitivity (DTH) reaction. This reaction develops when primed Th1 cells encounter their specific antigen. An inflammatory response evolves over 24-72 hours. In the tuberculin skin test, the injected antigen is protein derived from M.Tuberculosis. Th1 cells recognise peptide bound to MHC on APCs and are activated to secrete pro-inflammatory cytokines including IL2, IFN-gamma, TNF, chemokines and GM-CSF. There is recruitment of inflammatory cells predominantly macrophages to the site of antigen deposition, with activation of phagocytes. Some cytokines (TNF) as well as macrophage derived lytic enzymes cause local tissue destruction. CD8+ T-cells have also been implicated in DTH responses. The result is an indurated erythematous lesion at the site of injection which indicates previous exposure to TB.

[Q: 329] OnExamination - Basic Science

Which of the following would be most in keeping with a diagnosis of polymyalgia rheumatica?

- 1- raised creatinine kinase
- 2- increased alkaline phosphatase
- 3- sudden loss of vision in one eye
- 4- shoulder and pelvic girdle pain in 40-year-old man
- 5- erythema nodosum

Answer & Comments

Answer: 2- increased alkaline phosphatase

Liver enzymes are elevated in most patients. Visual disturbances are suggestive of temporal arteritis not PMR, and are due to ischaemic changes in ciliary arteries (optic

neuritis/infarction) and less commonly due to central artery occlusion. Raised CK in polymyositis. PMR is rare before the age of 50 years.

[Q: 330] OnExamination - Basic Science

Which of the following suggests a diagnosis of Hurler's Syndrome rather than Hunter's Syndrome?

- 1- X-linked inheritance
- 2- Mental retardation
- 3- Skeletal abnormalities
- 4- Cloudy cornea
- 5- Cardiomyopathy

Answer & Comments

Answer: 4- Cloudy cornea

Hunter's Syndrome (MPS-2) is of X-linked inheritance. The cornea are clear. The skeletal involvement tends to be mild with no gibbous present, though scoliosis is often found. Mental retardation and heart involvement are less severe than in Hurler's Syndrome. Hurler's Syndrome (MPS0) is autosomal recessive in inheritance and is associated with cloudy cornea. There is severe mental retardation, and gibbous deformation of the spine is characteristic. There is the characteristic coarse facies with hepatosplenomegaly.

[Q: 331] OnExamination - Basic Science

A 26-year-old man presented with exertional thigh cramps. He described his urine turning to burgundy colour especially after prolonged exertion. Investigations in the recent past had excluded presence of any significant ischaemic or inflammatory condition affecting his lower limbs.

On examination, pulse was 74 beats per minute, blood pressure was 122/66 mmHg,

heart sounds were normal and there was no organomegaly found on abdominal examination.

Investigations:

serum urea 4.6 mmol/L (2.5-7.5)

serum creatinine 88 µmol/L (60-110)

serum corrected Calcium 2.32 mmol/L (2.2-2.6)

serum phosphate 0.92 mmol/L (0.8-1.4)

serum creatine kinase 76 U/L (24-195)

urine tested positive for myoglobin

What is the next most appropriate investigation?

- 1- bone marrow examination for gauchers cells
- 2- kidney biopsy
- 3- liver biopsy
- 4- muscle biopsy
- 5- urine for porphyrins

Answer & Comments

Answer: 4- muscle biopsy

The exertional thigh cramps, the presence of myoglobin and change in colour of urine after exercise suggests glycogen storage disease type V - McArdles syndrome. The most appropriate investigation for this is muscle biopsy which reveals subsarcolemmal deposits of glycogen appear at the periphery of fibres.

[Q: 332] OnExamination - Basic Science

A 24-year-old man presented with exertional thigh cramps. He described his urine turning to burgundy colour especially after prolonged exertion. Investigations in the recent past had excluded presence of any significant ischaemic or inflammatory condition affecting his lower limbs.

On examination, his pulse was 74 beats per minute, blood pressure was 122/66 mmHg, heart sounds were normal and there was no organomegaly found on abdominal examination.

Investigations:

serum sodium 132 mmol/L (135-145)

serum urea 4.4 mmol/L (2.5-7.5)

serum creatinine 88 µmol/L (60-110)

serum corrected calcium 2.32 mmol/L (2.2-2.6)

serum phosphate

serum creatine kinase 88 U/L (24-195)

urine tested positive for myoglobin

What is the most likely diagnosis?

- 1- acute intermittent porphyria
- 2- alkaptonuria
- 3- gauchers disease
- 4- glycogen storage disease
- 5- multiple myeloma

Answer & Comments

Answer: 4- glycogen storage disease

The exertional thigh cramps, the presence of myoglobin and change in colour of urine after exercise suggests glycogen storage disease type V - McArdles syndrome.

[Q: 333] OnExamination - Basic Science

A 78-year-old man who lives alone and prepares his own food is found to have numerous ecchymotic hemorrhagic areas around his hair follicles. The hairs are fragmented and several hematomas are present in the muscles of the arms and legs. Except for the absence of teeth, the rest of the physical examination is unremarkable. Laboratory examination reveals a normal

Prothrombin time, APTT and full blood count is normal except for a hematocrit of 28%.

Deficiency of which of the following is most likely to explain this patients presentation?

- 1- Folate
- 2- Vitamin A
- 3- Vitamin C
- 4- Vitamin K
- 5- Zinc

Answer & Comments

Answer: 3- Vitamin C

This man has features of scurvy. Scurvy is the clinical state arising from dietary deficiency of vitamin C (ascorbic acid). It results in impaired collagen synthesis. The typical pathological manifestations of vitamin C deficiency are noted in dentine, osteoid and capillary vessel wall tissues

Clinical features include gum swelling, friability, bleeding, and infection with loose teeth; mucosal petechiae; scleral icterus (late, probably secondary to hemolysis); and pale conjunctiva are seen. Fractures, dislocations, and tenderness of bones are common in children. Bleeding into muscles and joints may be seen. Perifollicular hyperkeratotic papules, perifollicular hemorrhages, purpura, and ecchymoses are the classical skin manifestation of scurvy.

[Q: 334] OnExamination - Basic Science

Which of the following is a characteristic feature of acute intermittent porphyria?

- 1- autosomal recessive inheritance
- 2- excessive faecal protoporphyrin excretion
- 3- excessive urinary porphobilinogen during an acute attack
- 4- hypernatraemia during attacks
- 5- photosensitivity

Answer & Comments

Answer: 3- excessive urinary porphobilinogen during an acute attack

Features of acute intermittent porphyria include urinary porphobilinogen excretion raised between attacks, hyponatraemia during an acute attack and autosomal dominant inheritance.

[Q: 335] OnExamination - Basic Science

Proteins known as cyclins:

- 1- Regulate the menstrual cycle
- 2- Are differentially expressed throughout the cell cycle
- 3- Regulate antibody production
- 4- Regulate the cycling of receptors between the cell surface and the cytoplasm
- 5- Regulate DNA transcription

Answer & Comments

Answer: 2- Are differentially expressed throughout the cell cycle

Cyclins are key regulators of the cell cycle, different cyclins are expressed at different stages of the cell cycle.

[Q: 336] OnExamination - Basic Science

Phosphorylation of protein tyrosine residues is associated with:

- 1- Cell signalling pathways
- 2- Protein degradation
- 3- Alzheimer's disease
- 4- Protein synthesis
- 5- Creutzfeldt-Jacob Disease

Answer & Comments

Answer: 1- Cell signalling pathways

Phosphorylation of specific tyrosine residues of components of cell signalling pathways is often a key event in the activation of the pathway.

[Q: 337] OnExamination - Basic Science

Apoptosis is the process of programmed cell death and occurs in cells that have damaged DNA. A mediator of this process is a tumour suppressor gene that inhibits mitosis and promotes apoptosis.

This gene is:-

- 1- bcl-2
- 2- caspases
- 3- fas (CD95)
- 4- p53
- 5- ras

Answer & Comments

Answer: 4- p53

bcl-2 is an inhibitor of apoptosis. fas is a cell receptor and caspases are present in all cells both promote apoptosis but are not tumour suppressor genes. ras is an oncogene.

[Q: 338] OnExamination - Basic Science

Which of the following organelles contains enzymes responsible for the digestion of constituents of cells and tissues?

- 1- endoplasmic reticulum
- 2- Golgi apparatus
- 3- lysosomes
- 4- microtubules
- 5- mitochondria

Answer & Comments

Answer: 3- lysosomes

The lysosomes contain the enzymes and molecules such as oxidases, free radical etc responsible for the breakdown of intracellular components. Microtubules are involved in mitotic processes and intracellular transportation. The mitochondria produce energy for cellular functions.

[Q: 339] OnExamination - Basic Science

Apoptosis is induced by:

- 1- Activation of caspases
- 2- The MAP kinase pathway
- 3- DNA synthesis
- 4- Antibodies
- 5- Necrosis

Answer & Comments

Answer: 1- Activation of caspases

A key event in the initiation of apoptosis is the activation of a cascade of cysteine-aspartate specific proteases known as caspases.

[Q: 340] OnExamination - Basic Science

Northern blotting is a technique that can be used to detect:

- 1- Antibodies
- 2- DNA
- 3- RNA
- 4- Protein
- 5- Plasmids

Answer & Comments

Answer: 3- RNA

Northern blotting is a means of detecting RNA, frequently used to quantify specific mRNA transcript levels.

[Q: 341] OnExamination - Basic Science

Which of the following statements regarding messenger RNA (mRNA) is correct?

- 1- mRNA never contains introns.
- 2- mRNA is translated into proteins in the nucleus.
- 3- mRNA contains the bases cytosine and thymine.
- 4- reverse transcriptase uses mRNA as a template to produce complementary DNA.
- 5- mRNA is used in the Southern blotting technique.

Answer & Comments

Answer: 4- reverse transcriptase uses mRNA as a template to produce complementary DNA.

The structure of mRNA is similar to DNA except that uracil replaces thymine as one of the bases. Both coding (exons) and non-coding regions of DNA are initially transcribed into mRNA. Splicing is required for mature mRNA to be produced only consisting of introns. Translation occurs in the cytoplasm. Southern blotting is a technique that uses denatured fragments of DNA in a gel to bind to DNA probes in order to detect the presence of particular genes or sequences of DNA. The enzyme reverse transcriptase can be used by viruses to insert viral mRNA into the host genome.

Hannam et al. MRCP (Paediatrics) Part 1 MCQs. page 121 ?WB Saunders. Reproduced with permission.

[Q: 342] OnExamination - Basic Science

Which of the following statements regarding myosin is correct?

- 1- It drives smooth muscle contraction
- 2- Forms filaments in a pentameric array with two heavy chains and three light chains
- 3- myosin heavy chain mutations are associated with development of familial hypertrophic cardiomyopathy
- 4- Contains an cAMP-binding sites
- 5- Has no function when not part of a filament

Answer & Comments

Answer: 3- myosin heavy chain mutations are associated with development of familial hypertrophic cardiomyopathy

Myosin drives striated muscle contraction, and can be divided into 2 groups ?conventional (class II myosins) which form filaments in a hexameric array of 2 heavy chains and two pairs of light chains. Unconventional myosins do not form filaments and perform varied functions in a broad range of cells (eg organelle transport, endocytosis). Myosin contains an ATP and actin-binding sites. Other myosin related genetic disorders besides the heavy chain mutations in cardiomyopathy include Carney complex (trismus-pseudocamptodactyly), Type 1b Usher syndrome and non-syndromic deafness.

[Q: 343] OnExamination - Basic Science

In a study of elderly patients with atrial fibrillation, patients receiving warfarin (n= 6000), 6% had strokes or died as a consequence of stroke, whereas in subjects treated with aspirin (n = 8000), 9 % had stroke or death from a stroke over the 3 year study period (p=0.001). The risk of stroke in an untreated population with atrial fibrillation over this time was 12%.

Which of the following percentages is the approximate annual incidence of stroke in the treated population in this study?

- 1- 2.6%
- 2- 3.3%
- 3- 5.5%
- 4- 6.9%
- 5- 7.7%

Answer & Comments

Answer: 1- 2.6%

One needs to calculate the incidence as follows:

In the group treated with warfarin there were 360 strokes (6% of 6000). In the aspirin treated group there were 720 strokes (9% of 8000). Thus, there are 1080 strokes amongst the treated population (n=14000) over a three year time period. Therefore there are 360 strokes annually in the treated group (14000) giving an annual incidence of stroke of approx 2.6%

Note: remember to divide by three since the study lasted 3 years and the figures given are for the 3 years incidence rates.

[Q: 344] OnExamination - Basic Science

A new rapid test is developed for the screening of Malaria. Blood from 200 patients were analysed by the gold standard laboratory technique and by the new method. There were 100 positive results with the gold standard technique but there were only 50 positive results using the new technique.

Approximately which of the following values reflects the negative predictive value of the new technique?

- 1- 33%
- 2- 50%
- 3- 66%
- 4- 75%
- 5- 90%

Answer & Comments

Answer: 3- 66%

The Negative Predictive Value is Number of True negatives / (number of true negatives + False negatives). It reflects the proportion of patients with negative test results who are correctly diagnosed.

In the new technique there were 100 true positives (i.e. 100 true negatives) and 50 False negatives (where the new test missed the diagnosis). Thus the negative predictive value is $100/(100+50) = 66\%$.

[Q: 345] OnExamination - Basic Science

A researcher compared the mean scores for nausea on a rating scale between standard therapy and a new drug in the treatment of chemotherapy induced nausea.

Which one of the following is the most appropriate statistical test?

- 1- Chi-square test
- 2- Paired T-test
- 3- Life table analysis (log rank test)
- 4- Pearson correlation
- 5- Unpaired T-test

Answer & Comments

Answer: 5- Unpaired T-test

The two-sample unpaired t test is used to test the null hypothesis that the two populations corresponding to the two random samples are equal.

For a paired t test, the data is dependent, i.e. there is a one-to-one correspondence between the values in the two samples. For example, the same subject measured before and after a process change, or the same subject measured at different times.

[Q: 346] OnExamination - Basic Science

A cohort study of 7,500 patients aimed to find out whether the use of olive oil in cooking has an impact on cardiovascular disease. Approximately half the patients used olive oil in cooking and half used animal fat.

Which of these is a disadvantage of a cohort study?

- 1- It is not possible to measure the incidence/risk of a disease
- 2- They are susceptible to recall bias; there is a differential ability of patients to remember exposure to a risk factor
- 3- They are not suitable when exposure to risk factors is rare
- 4- They can only provide information about one outcome
- 5- When the outcome of interest is rare a very large sample size is needed.

Answer & Comments

Answer: 5- When the outcome of interest is rare a very large sample size is needed.

A cohort study takes a group of individuals and follows them for a period of time the aim being to study whether the exposure to a particular aetiological factor has an effect on the incidence of disease. As such they are relatively time consuming and expensive to perform. Advantages include being able to study exposure factors that are rare and being less susceptible to recall bias than cohort studies. They are also able to measure the incidence/risk of a disease. Results are usually expressed as the relative risk of developing the disease given exposure to the aetiological factor.

[Q: 347] OnExamination - Basic Science

Which of the following statements is correct regarding standard error of the mean (SEM)

and standard deviation (SD)?

- 1- Standard error of mean is calculated by taking the square root of the standard deviation of the sample means
- 2- Standard deviation invariably falls with increasing sample size
- 3- Standard error of mean increases with sample size
- 4- if standard deviation is greater than the mean the distribution is negative
- 5- Student's t test is a non-parametric test

Answer & Comments

Answer: 4- if standard deviation is greater than the mean the distribution is negative

The Standard error of the Mean = SD/\sqrt{n} . SD does not necessarily fall with sample size as the distribution of values may increase and hence SD increase. SEM would decrease with sample size as can be seen in the above calculation.

The SD would only be greater than the mean if the sample was Negatively Distributed - i.e. the data was negative. This is not the same as 'negatively skewed' where the distribution of data about the mean tails off to the left with the majority of points being greater (the median and the mode are greater than the mean). This question, is a trick ... and quite a trivial one at that. A negative distribution's mean would be, of course, negative but the standard deviation would still be a positive number!

Student's T test is a parametric test comparing normally distributed data.

[Q: 348] OnExamination - Basic Science

Statistical independence may be assumed in which of the following circumstances?

- 1- Successive measures taken on the same individual.

- 2- Stratified sampling from a target population.
- 3- Two matched individuals in a case control study.
- 4- Response to antibiotics of children with otitis media who have a CRP of above 100.
- 5- Diagnosis of pyloric stenosis by ultrasound scan in patients attending a tertiary referral centre.

Answer & Comments

Answer: 2- Stratified sampling from a target population.

Independent events do not affect each other. Thus, the chance of event A occurring is completely unaffected by the chance of B occurring. Two measures on the same individual are clearly dependent, but the same also applies to 2 matched individuals such as in a case control study. The outcome of patients attending a tertiary referral centre is bound to depend on the patients referred, and the facilities and expertise available at that centre. In patients with elevated CRP, one might suspect that there is a higher risk of bacterial otitis media, and, therefore, one might expect a greater response to antibiotics. The response to antibiotics is, therefore, dependent to some extent on the raised CRP.

[Q: 349] OnExamination - Basic Science

In a study of elderly patients with atrial fibrillation, patients receiving warfarin (n=6000) were found to have a rate of stroke of 6% whereas subjects treated with aspirin (n=8000) had a stroke rate of 9.9% over the 3 year study period (p=0.001). The risk of stroke in an untreated population with atrial fibrillation over this time was 12%.

To what do these numbers relate?

- 1- Absolute risk
- 2- Incidence

- 3- Odds risk
- 4- Prevalence
- 5- Relative risk

Answer & Comments

Answer: 2- Incidence

These numbers relate to the INCIDENCE of stroke occurring in various populations over a specified period of time. Prevalence is the numbers of patients with a specified disorder at any one time point. Absolute risk reduction refers to the reduction in the number of patients with stroke following a specific intervention eg ARR of stroke with warfarin vs aspirin is 3.3% over 3 years. Relative risk reduction is $3.3/9.9 \times 100 = 33\%$.

[Q: 350] OnExamination - Basic Science

In significance testing which of these statements is correct?

- 1- A Type I error is to reject the alternative hypothesis when it should be accepted.
- 2- A Type II error is to accept the alternative hypothesis when it should be rejected.
- 3- The probability associated with a Type I error is the significance level.
- 4- The significance level is determined at the end of a significance test.
- 5- The significance level is always set to 5%.

Answer & Comments

Answer: 3- The probability associated with a Type I error is the significance level.

The null hypothesis is that there is no differences between two groups. The alternative hypothesis is that there is a difference. Rejecting the null hypothesis when there really is no difference between the two groups is a Type 1 error. Accepting the null hypothesis (rejecting the alternative

hypothesis) when there is a difference is a type 2 error. Rejection of the null hypothesis depends on the probability - significance level which is usually (but not always) at $p < 0.05$.

[Q: 351] OnExamination - Basic Science

An experienced group of surgeons report on a randomised placebo-controlled trial comparing a particular carotid surgery technique as compared to a sham operation. Their study concludes that 'using this advanced surgical technique reduces the risk of stroke from 4.3% to 3.8% ($p < 0.05$)'.

What has this study proved about the surgical procedure?

- 1- Acceptability
- 2- Effectiveness
- 3- Efficacy
- 4- Safety
- 5- Usefulness

Answer & Comments

Answer: 3- Efficacy

This is an experienced group of vascular surgeons working in ideal conditions. Similar studies have been reported for carotid surgery but it has been difficult to prove their usefulness outside areas of expertise. It is often difficult to generalise the findings in a study group to everyday practice. Efficacy = the effect of something under ideal or laboratory conditions, Effectiveness = the effect of something in the real world.

[Q: 352] OnExamination - Basic Science

Which of the following statements is true regarding statistical interpretation of data?

- 1- The incidence equals the number of newly affected individuals divided by the number

of people at risk for the disease for a given duration.

- 2- The prevalence is readily distinguished from the incidence in relation to cancers.
- 3- The mortality rate is a kind of cumulative prevalence rate.
- 4- The cumulative incidence rate is usually given over a 10 year period.
- 5- The prevalence rate is defined as the total number of cases divided by the total number in the population.

Answer & Comments

Answer: 1- The incidence equals the number of newly affected individuals divided by the number of people at risk for the disease for a given duration.

The incidence can be thought of as the number of new cases occurring in a given time. The cumulative incidence rate is usually reported over a year. Prevalence equals the total number of cases divided by the total number of at risk. In diseases for which the exact onset cannot be determined such as cancers, it may be difficult to distinguish between incidence and prevalence. Mortality rate is a special kind of cumulative incidence rate, with deaths in the numerator and population in the denominator. Case fatality rate, has deaths in the numerator and the number of people with a specific disease in the denominator.

[Q: 353] OnExamination - Basic Science

A trial is proposed to see whether excess alcohol use is a risk factor for osteoporosis. It is decided to perform a case-control study rather than a cohort study.

Which of these is an advantage of a case-control study?

- 1- It can provide information on a wide range of outcomes

- 2- It is possible to measure the incidence of a disease directly
- 3- It is possible to study exposure to factors that are rare
- 4- It is relatively quick, cheap and easy to perform
- 5- The time sequence of events can be assessed

Answer & Comments

Answer: 4- It is relatively quick, cheap and easy to perform

A case-control study compares the characteristics of a group of patients with the disease with a control group of patients who do not have the disease. Other advantages of case-control studies are that they are particularly suitable for rare diseases, a wide range of risk factors can be investigated and there is no loss to follow up. Results are usually quoted as an odds ratio. The incorrect answers are all advantages of cohort studies.

[Q: 354] OnExamination - Basic Science

A new antiplatelet agent has been proven to reduce the risk of stroke in a year from 10% in patients treated with conventional treatment to 6% in patients treated with conventional treatment plus the new agent. The cost of this new drug is ?00 per month.

How much extra would a hospital need to spend to prevent one stroke.

- 1- ?200
- 2- ?000
- 3- ?8000
- 4- ?0000
- 5- ?00000

Answer & Comments

Answer: 4- ?0000

The 'Absolute Risk Reduction' is $10\% - 6\% = 4\%$. The 'Number Needed to Treat' to prevent a stroke therefore equals $100 / 4 = 25$. 25 patients would need to be treated at a cost of ?00/month for 12 months to prevent a stroke which gives the total cost as ?0000.

[Q: 355] OnExamination - Basic Science

In a study of 26000 females, 1300 subjects were found to have either overt or subclinical hypothyroidism. Within this group, the risk of demonstrating either overt or subclinical hypothyroidism was therefore 5%.

What is the best descriptive term of this 5% risk?

- 1- Absolute risk
- 2- Incidence
- 3- Prevalence
- 4- Relative risk
- 5- Specificity

Answer & Comments

Answer: 3- Prevalence

This is the risk of either subclinical or overt hypothyroidism in a female population at any specific time which is the prevalence. This is defined as the rate of a disorder in a specified population at a specified time. Incidence refers to the number of new cases of a disorder developing over a specific time.

[Q: 356] OnExamination - Basic Science

A randomised double-blind placebo controlled study of a cholesterol-lowering drug in the primary prevention of coronary heart disease was conducted over a five-year follow up period. The absolute risk of myocardial infarction in the group-receiving placebo during this time was 10 per cent.

The relative risk of those given the cholesterol lowering medication was 0.8.

What number of patients will need to be treated with active drug for five years to prevent one myocardial infarction?

- 1- 20
- 2- 40
- 3- 50
- 4- 80
- 5- 100

Answer & Comments

Answer: 3- 50

The absolute risk of MI in the treatment group is $10\% \times 0.8 = 8\%$ (as they have a relative risk of 0.8 as compared to the placebo group). $NNT = 1 / \text{absolute relative risk}$. ARR is the risk in control group - risk in treated group. Therefore the ARR is $10\% - 8\%$ and the NNT for that period is $1/0.02 = 50$.

[Q: 357] OnExamination - Basic Science

In a study to find out if concentration of drug X is related to weight, subjects were given 500 mg of the drug and serum levels were measured two hours later.

Which of the following is the best statistical test to evaluate the results?

- 1- Student's paired t-test
- 2- Chi squared test
- 3- Student's unpaired t-test
- 4- Log regression analysis
- 5- Pearsons coefficient

Answer & Comments

Answer: 4- Log regression analysis

Drug concentrations are measured two hours after consumption and the variable of weight is to be factored in on the drugs

pharmacokinetics. Consequently the most appropriate statistical test would be log regression analysis.

[Q: 358] OnExamination - Basic Science

Which of the following would invalidate the use of the unpaired t test in the comparison of mean drug concentrations between two groups of subjects?

- 1- Insufficient statistical power
- 2- Non-normal distribution of data
- 3- small standard error
- 4- small sample size
- 5- unequal sample sizes in both groups

Answer & Comments

Answer: 2- Non-normal distribution of data

The t tests can only be used for parametric (normally distributed) data. Insufficient statistical power a consequence of numbers recruited would not invalidate the results of a t test as it is likely the results would be unlikely to show any difference with too few subjects although it is possible that if the differences were large then irrespective of prior power calculations differences might be seen.

[Q: 359] OnExamination - Basic Science

In a study of 950 subjects with a BMI below 25, a new serological marker for coeliac disease was assessed against the gold standard test of jejunal biopsy. The following results were obtained:

	Test positive	Test negative
Biopsy positive	40	10
Biopsy negative	60	840

What is the sensitivity of this test?

- 1- 40%
- 2- 55%
- 3- 66%
- 4- 80%
- 5- 93%

Answer & Comments

Answer: 4- 80%

Sensitivity relates to the probability that the person with a disease will be correctly identified with the disease. Therefore, in this study, 50 subjects have the disease, of whom 40 are correctly identified with the disease giving a sensitivity of 80%. The specificity is the probability that a person without the disease will be correctly identified by the test. In this case, there are 900 subjects without the disease of whom 840 were identified by the test - giving a specificity of 93%

[Q: 360] OnExamination - Basic Science

A new test is developed for the diagnosis of HIV. Blood from 10,000 patients were analysed by the gold standard technique and by the new method. There were 100 positive results with the gold standard technique but there were 150 positive results using the new technique. *Approximately which of the following values reflects the positive predictive value of the new technique.*

- 1- 33%
- 2- 50%
- 3- 66%
- 4- 75%
- 5- 90%

Answer & Comments

Answer: 3- 66%

The positive predictive value is Number of True Positives/(No of true positives + False

positives). In the new technique there were 100 true positives and 50 False Positives. Thus the positive predictive value is 66%.

[Q: 361] OnExamination - Basic Science

A new rapid test is developed for the screening of Leptospirosis. Blood from 100 patients were analysed by the gold standard laboratory technique and by the new method. There were 20 positive results with the gold standard technique but there were 40 positive results using the new technique.

Approximately which of the following values reflects the positive predictive value of the new technique?

- 1- 33%
- 2- 50%
- 3- 66%
- 4- 75%
- 5- 90%

Answer & Comments

Answer: 2- 50%

The positive predictive value is Number of True Positives/(No of true positives + False positives). In the new technique there were 20 true positives and 20 False Positives. Thus the positive predictive value is $20/(20+20) = 50\%$.

[Q: 362] OnExamination - Basic Science

In a double blind controlled trial assessing the impact of a new antihypertensive in the treatment of stroke versus conventional antihypertensive therapy in the secondary prevention of stroke, the authors report an absolute annual risk reduction in the incidence of stroke of 0.5% and a relative risk reduction of 20% ($p=0.032$). The cost of the new treatment is £100 more expensive per year than conventional therapy.

What would be the cost of implementing the new therapy for each stroke prevented?

- 1- ?000
- 2- ?000
- 3- ?0,000
- 4- ?0,000
- 5- ?0,000

Answer & Comments

Answer: 5- ?0,000

In this case, the annual incidence of stroke is reduced by 0.5% and treatment is £100 more than conventional therapy. The relative risk reduction of 20% means that the annual risk of stroke is 2.5% (0.5% is 1/5 of 2.5%) in the conventionally treated group. Thus for every 200 patients treated 1 less stroke would occur with the new drug versus the conventional therapy. Number Needed to Treat (NNT) is therefore 200 per year to prevent one stroke. Thus the annual cost of this treatment associated with preventing one stroke, despite its significant reduction in stroke reduction ($p=0.032$) would be:

$200 \text{ patients} \times £100 = 20,000.$

[Q: 363] OnExamination - Basic Science

A study of the intellectually handicapped was performed. The 112 subjects, put through program A, showed an increase in their mean IQ score of 6 points. The 115 subjects, put through program B, showed an increase in their mean IQ score of 4. The p value was >0.05 .

Which of the following is true:

- 1- the numbers are too large for a Student t-test
- 2- the study demonstrates the usefulness of program A
- 3- the distribution of individual values is not important

- 4- even though the difference between the means is not significant it would be appropriate to calculate confidence intervals
- 5- the above results would be found by chance in less than 1:20

Answer & Comments

Answer: 4- even though the difference between the means is not significant it would be appropriate to calculate confidence intervals

a-The t-test could be used in the comparison of data and the larger the sample size the more meaningful the data. b-A is no more useful than B or even simply repeating an IQ test? c+d This gives us an idea of the distribution of the data. Confidence intervals may provide more meaningful data concerning the study. e-The chances are greater than 1 in 20 as P is greater than 0.05.

[Q: 364] OnExamination - Basic Science

A publication describes a new diagnostic test for myocardial infarction. You want to know what proportion of patients with a confirmed myocardial infarction will be identified by the test.

Which one of the following measurements would indicate this?

- 1- Accuracy
- 2- Negative predictive value
- 3- Positive predictive value
- 4- Sensitivity
- 5- Specificity

Answer & Comments

Answer: 4- Sensitivity

The specificity of a test is the probability that a test will produce a true negative result when

used on an unaffected population, whereas the sensitivity of a test is the probability that it will produce a true positive result when used on an affected population (as determined by a reference or "gold standard"). The positive predictive value of a test is the probability that a person is affected when a positive test result is observed. The negative predictive value of a test is the probability that a person is not affected when a negative test result is observed. Accuracy is expressed through the above four parameters.

[Q: 365] OnExamination - Basic Science

In a study of 1000 subjects with adrenal incidental tumours, a new serological marker for adrenal carcinoma was assessed against formal histology. The following results were obtained:

	Test positive	Test negative
Histology positive	40	10
Histology negative	50	900

To what does the specificity approximate?

- 1- 50%
- 2- 60%
- 3- 70%
- 4- 80%
- 5- 90%

Answer & Comments

Answer: 5- 90%

Sensitivity relates to the probability that the person with a disease will be correctly identified with the disease. Therefore, in this study, 50 subjects have adrenal carcinoma, of whom 40 are correctly identified with the disease giving a sensitivity of 80%. The specificity is the probability that a person without the disease will be correctly identified by the test. In this case, there are 950 subjects

without adrenal carcinoma of whom 900 were identified by the test (giving a specificity of ~95%.)

[Q: 366] OnExamination - Basic Science

A letter to a medical journal suggested that an established antidepressant may cause photosensitivity. The manufacturer wished to set up a study to determine rapidly and efficiently whether this was a true association.

Which one of the following techniques is most appropriate?

- 1- A case control study
- 2- A dose ranging study
- 3- A double blind, randomised, placebo controlled study
- 4- A meta-analysis
- 5- A sequential trial

Answer & Comments

Answer: 4- A meta-analysis

A sequential trial is one in which the data are analysed after each participant's results become available, and the trial continues until a clear benefit is seen in one of the comparison groups, or it is unlikely that any difference will emerge. The main advantage of sequential trials is that they will be shorter than fixed length trials when there is a large difference in the effectiveness of the interventions being compared. Their use is restricted to conditions where the outcome of interest is known relatively quickly.

In a case control study, patients who have developed a disease are identified and their past exposure to aetiological factors is compared with that of controls who do not have the disease. A double-blind randomized placebo controlled study does not seem appropriate in this case, and a dose-ranging study would be used in the early stages of drug development to identify common side

effects, perhaps toxicity, and threshold efficacy doses. The most appropriate study would probably be a meta-analysis. This is because the drug is in the market place, large studies will have taken place in order for it to obtain its license, the data is available relatively rapidly (compared with the other options in this question), the analysis could be carried out efficiently (cheaply if one were being cynical), and the results of the trial would also be available rapidly.

[Q: 367] OnExamination - Basic Science

In a study of blood pressures in a specific ethnic population, the researcher is concerned that his spread of blood pressures is larger than that described in the general population.

Which of the following terms most appropriately describes the spread of blood pressures?

- 1- Mean
- 2- Median
- 3- Mode
- 4- Standard deviation
- 5- Standard error of the mean

Answer & Comments

Answer: 4- Standard deviation

Standard deviation is a measure of the spread of observations about the mean. It is based on the deviation of each observation from the mean value.

Each value is squared, summed and divided by the total number of observations less one. The standard deviation is the square root of this value.

[Q: 368] OnExamination - Basic Science

A large multi-centre secondary prevention study reports a reduction in the annual

incidence of recurrent subarachnoid haemorrhage from 10% in a medically treated group versus 6% in the group treated with medical therapy plus radiological intervention ($p < 0.005$). The cost of the new treatment is ?000 per patient.

In the first year of treatment, what would be the predicted additional cost of preventing a single recurrent subarachnoid haemorrhage?

- 1- ?000
- 2- ?2000
- 3- ?0000
- 4- ?5000
- 5- ?0000

Answer & Comments

Answer: 4- ?5000

This study shows that annual rate of recurrent subarachnoid haemorrhage is reduced from 10% to 6%. Therefore, if you treated 100 patients for one year you would expect 10 patients with Subarachnoid Haemorrhage in the medically treated group vs 6 patients in the medical plus radiological intervention group - a reduction of 4 patients per hundred. Therefore you would need to treat 25 patients (4/100) to expect one less case of Subarachnoid Haemorrhage. Thus the extra cost of this would be $25 \times 3000 = ?5000$

[Q: 369] OnExamination - Basic Science

In a primary prevention study of stroke comparing a new antihypertensive with conventional antihypertensive therapy, the number of patients who had a stroke over the study period was 200 in group 1 with the new therapy ($n=5200$) versus 250 with conventional therapy ($n=4750$).

Which of the following is the approximate odds ratio for the new therapy?

- 1- 0.25

- 2- 0.5
- 3- 0.75
- 4- 1
- 5- 1.5

Answer & Comments

Answer: 3- 0.75

An odds ratio is calculated by dividing the odds in the treated or exposed group by the odds in the control group. Studies generally try to identify factors that cause harm - those with odds ratios greater than one.

The new therapy odds of an event is $200/5000$ (patients without an event $5200-200$) = 0.04. Group 2's odds event rate is $250/4500$ ($4750-250$) = 0.055. The odds ratio is therefore:

$$0.04/0.055 = 0.73$$

This odds ratio is less than 1, indicating an overall benefit of therapy.

[Q: 370] OnExamination - Basic Science

A clinical investigation examined the effectiveness of a new test for diagnosing Pancreatic carcinoma. The sensitivity was reported as 70%.

Which one of the following statements is correct?

- 1- 70% of people will be correctly classified as having or not having the disease
- 2- 70% of people with an abnormal test result will have the disease
- 3- 70% of people with a normal test result will not have the disease
- 4- 70% of people with the disease will have an abnormal test result
- 5- 70% of people with the disease will have a normal test result

Answer & Comments

Answer: 4- 70% of people with the disease will have an abnormal test result

Sensitivity is the conditional probability that the test will be positive if the condition is present). Specificity is the conditional probability that the test will be negative if the condition is absent. Therefore, interpreting the data there is a 70% probability of the test being positive when tested in a group of patients with the disease.

[Q: 371] OnExamination - Basic Science

A publication assesses a new diagnostic test for thyroid cancer.

Which of the following terms would reflect the number of cases of thyroid cancer correctly identified by this new test?

- 1- accuracy
- 2- negative predictive value
- 3- positive predictive value
- 4- Sensitivity
- 5- Specificity

Answer & Comments

Answer: 4- Sensitivity

The specificity of a test is the probability that a test will produce a true negative result when used on an unaffected population, whereas the sensitivity of a test is the probability that it will produce a true positive result when used on an affected population (as determined by a reference or "gold standard"). The positive predictive value of a test is the probability that a person is affected when a positive test result is observed. The negative predictive value of a test is the probability that a person is not affected when a negative test result is observed. Accuracy is expressed through the above four parameters.

[Q: 372] OnExamination - Basic Science

A study is designed to test the accuracy of faecal occult blood testing in excluding a certain type of bowel cancer. Faecal occult bloods are compared to a gold standard which consists of a battery of tests and pathological diagnosis. In the study 200 prospective patients undergo faecal occult blood testing and are followed up with the other investigations.

The results showed that malignancy was present in 100 patients but the faecal occult blood testing was positive in only 90 patients.

Approximately which of the following values reflects the negative predictive value of the faecal occult blood testing in this study?

- 1- 33%
- 2- 50%
- 3- 66%
- 4- 75%
- 5- 90%

Answer & Comments

Answer: 5- 90%

The Negative Predictive Value is Number of True negatives / (number of true negatives + False negatives). It reflects the proportion of patients with negative test results who are correctly diagnosed.

In the new technique there were 100 true positives who had the disease (i.e. 100 true negatives) and 10 False negatives (where the faecal occult blood test missed the diagnosis). Thus the negative predictive value is $100/(100+10) = 90.9\%$.

[Q: 373] OnExamination - Basic Science

In a study of 1000 patients with autoimmune hepatitis, a new serological test for the disease was assessed against diagnostic liver

biopsy. The following results were obtained:

	Test positive	Test negative
Histology positive	80	20
Histology negative	100	800

To what does the sensitivity of the new test approximate?

- 1- 50%
- 2- 60%
- 3- 70%
- 4- 80%
- 5- 90%

Answer & Comments

Answer: 4- 80%

Sensitivity relates to the probability that the person with a disease will be correctly identified with the disease. Therefore, in this study, 100 subjects have autoimmune hepatitis, of whom 80 are correctly identified with the new test giving a sensitivity of 80%. The specificity is the probability that a person without the disease will be correctly identified by the test. In this case, there are 900 subjects without autoimmune hepatitis of whom 800 were identified by the test - giving a specificity of ~89%.

[Q: 374] OnExamination - Basic Science

Adequate randomisation can be assumed in which of the following circumstances?

- 1- All consecutive patients attending a tertiary referral centre.
- 2- A sample using healthy volunteers.
- 3- A sample of those judged to be appropriate for inclusion in the study.
- 4- A sample based on a family cluster.
- 5- A stratified random sample.

Answer & Comments

Answer: 5- A stratified random sample.

The actual patients included in the study often differ substantially from what was initially intended. This dramatically alters one's interpretation of a study. The target population includes all those with a given disease, and is seldom fully accessible. The accessible population available for study may be biased in time or place. It is important to randomise when selecting a sample which are supposed to represent the target population. In simple randomisation, every member of the population is numbered, and a random sample is selected. In a stratified random sample, groups of interest are identified, and then randomisation occurs within those groups. In systematic sampling a "periodic" approach is used. This is not really random and is open to alteration and bias. In a cluster sample, a natural grouping of population is used (such as a family), but this may well be unrepresentative of the whole population. Classic errors in randomisation are:

" Consecutive sampling, which may well not be representative if the study time is short.

" Convenience sampling: strong potential for bias, with volunteers generally healthier than others.

" Judgmental sample: including those that you want only. The potential for systematic error is enormous.

[Q: 375] OnExamination - Basic Science

A study was performed to assess the usefulness of a new autoantibody test for the detection of suspected Hashimoto's disease. The test was undertaken in 1000 subjects who complained of tiredness and all test results were compared with FNA biopsy results which provided a gold standard for the diagnosis of Hashimoto's disease.

The following table lists the results:

	Antibody +ve	Antibody -ve	Total
Hashimoto's disease confirmed at FNA	35	15	50
No evidence of disease at FNA	30	920	950

Approximately, what is the sensitivity of the antibody test for the detection of Hashimoto's disease?

- 1- 50%
- 2- 60%
- 3- 70%
- 4- 80%
- 5- 90%

Answer & Comments

Answer: 3- 70%

The Sensitivity of a test is the ability of a test to identify those with the condition. In this example, 50 individuals had Hashimoto's disease according to the Gold standard test of biopsy, with 35 of these being identified by the antibody test.

$$35/50 \times 100 = 70\%$$

[Q: 376] OnExamination - Basic Science

A study of an established antihypertensive agent against placebo reports that the risk of death due to cardiac causes is lower on treatment. It gives 5-year mortality due to cardiac causes as 12% on placebo and 8% on treatment. The authors conclude that 'a 33% reduction in cardiac deaths is seen with treatment'.

The figure '33%' represents which of the following?

- 1- Absolute Risk Reduction

- 2- Control Event Rate
- 3- Experimental Event Rate
- 4- Number Needed to Treat
- 5- Relative Risk Reduction

Answer & Comments

Answer: 5- Relative Risk Reduction

An understanding of quantities discussed in 'Evidence-based medicine' is becoming increasingly important for the exam. If a drug reduces the incidence of heart attacks from 10% to 5% then ...

- " the control event rate (CER) is 10%
- " the experimental event rate (EER) is 5%
- " the relative risk reduction (RRR) is 50%
- " the absolute risk reduction (ARR) is 5%
- " the number needed to treat (NNT) is $100\% / 5\% = 20$

[Q: 377] OnExamination - Basic Science

In a trial of statin therapy in the secondary prevention of ischaemic heart disease, therapy is shown to reduce cardiovascular mortality from 12% to 8% over the 5 years duration of the study. In comparison with standard therapy, *what is the number of patients that need to be treated to prevent one death over five years?*

- 1- 5
- 2- 10
- 3- 20
- 4- 25
- 5- 50

Answer & Comments

Answer: 4- 25

The drug has reduced the risk of death post MI by 4% over 5 years. Therefore if 100 people were treated we could expect the prevention of 4 deaths. Therefore in order to prevent 1 death, 25 individuals would need to be treated.

[Q: 378] OnExamination - Basic Science

In a study assessing two different antiplatelet agents in the prevention of stroke, 10,000 subjects were randomised to receive either the standard therapy or the new therapy. Over the study period of five years, the side effect of major gastrointestinal bleeding was 3% in the standard therapy group compared with 2% in the new therapy group.

Which of the following is the absolute risk reduction associated with the new therapy in major GI bleeds?

- 1- 1%
- 2- 3%
- 3- 10%
- 4- 15%
- 5- 33%

Answer & Comments

Answer: 1- 1%

We are not told whether there is a significant difference between the two groups yet in the standard antiplatelet therapy group there is a risk of GI bleed of 3% vs 2% with the new therapy. This is a 1% absolute risk reduction and a 33% relative risk reduction (1/3). The number of people that would need to be treated with the new drug to avert the major effect of bleeding would be 100.

[Q: 379] OnExamination - Basic Science

Suppose you are attempting to find a disease-causing gene, and you have identified a number of families in which the disease is

transmitted. If you have no knowledge of the gene product and no reasonable candidate locus, *which of the following would be the first technique you would be most likely to use?*

- 1- Linkage analysis
- 2- DNA sequencing
- 3- Single strand conformation polymorphism (SSCP) analysis
- 4- Denaturing gradient gel electrophoresis (DGGE)
- 5- Fluorescence in situ hybridization (FISH)

Answer & Comments

Answer: 1- Linkage analysis

Linkage analysis. Southern blotting is a laboratory procedure in which DNA fragments that have been electrophoresed through a gel are transferred to a solid membrane, such as nitrocellulose. The DNA can then be hybridized with a labeled probe and exposed to X-ray film. Somatic cell hybridization is a physical gene mapping technique in which somatic cells from two different species are fused and allowed to undergo cell division. Chromosomes from one species are selectively lost, resulting in clones with only one or a few chromosomes from one of the species. FISH is a molecular cytogenetic technique in which labelled probes are hybridized with chromosomes and then visualized under a fluorescence microscope. SSCP is a technique for detecting variation in DNA sequence by running single-stranded DNA fragments through a non-denaturing gel. Fragments with differing secondary structure (conformation) caused by sequence variation will migrate at different rates.

[Q: 380] OnExamination - Basic Science

Which of the following genetic mutation is responsible for Marfan's syndrome?

- 1- Collagen

- 2- Elastin
- 3- Fibrillin
- 4- Microfilament
- 5- Microtubule

Answer & Comments

Answer: 3- Fibrillin

Marfan's syndrome occurs due to a mutation in the fibrillin gene. Most patients, who are prone to develop an aortic aneurysm as a component of Marfan syndrome, can be identified by detection of mutations in the fibrillin-1 gene. Patients with the rarer form of Marfan's syndrome, which is characterized by contractural arachnodactyly instead of loose joints, can usually be identified by detection of a mutation in the fibrillin-2 gene that is similar in structure to the gene for fibrillin-1. Preliminary data suggest that patients with mutations in the fibrillin-2 gene are not prone to develop aneurysms.

[Q: 381] OnExamination - Basic Science

Which of the following does N-acetylcysteine replenish?

- 1- Cystathionine
- 2- Cytochrome P450
- 3- Glucuronyl transferase
- 4- Glutathione
- 5- Sulfatase

Answer & Comments

Answer: 4- Glutathione

Acetylcysteine, the N-acetyl derivative of the naturally occurring amino acid, L-cysteine, is a mucolytic agent and sulfhydryl donor acting as an antidote for paracetamol overdose.

[Q: 382] OnExamination - Basic Science

In one gene mapping technique, denatured DNA from metaphase chromosomes is hybridized with a radioactively labeled probe. This DNA is then exposed to film to reveal the approximate chromosomal location of the DNA in the probe.

Which technique does this best describe?

- 1- Southern blotting
- 2- In situ hybridization
- 3- Somatic cell hybridization
- 4- Fluorescence in situ hybridization
- 5- Single strand conformation polymorphism (SSCP) analysis

Answer & Comments

Answer: 2- In situ hybridization

The technique described is 'in situ hybridization'.

Southern blotting is a laboratory procedure in which DNA fragments that have been electrophoresed through a gel are transferred to a solid membrane, such as nitrocellulose. The DNA can then be hybridized with a labeled probe and exposed to X-ray film. Somatic cell hybridization is a physical gene mapping technique in which somatic cells from two different species are fused and allowed to undergo cell division. Chromosomes from one species are selectively lost, resulting in clones with only one or a few chromosomes from one of the species. FISH is a molecular cytogenetic technique in which labelled probes are hybridized with chromosomes and then visualized under a fluorescence microscope. SSCP is a technique for detecting variation in DNA sequence by running single-stranded DNA fragments through a non-denaturing gel. Fragments with differing secondary structure (conformation) caused by sequence variation will migrate at different rates.

[Q: 383] OnExamination -
Emergency medicine

Which one of the following is a recognised treatment option in poisoning?

- 1- ethanol for isopropyl alcohol poisoning
- 2- glucagon for cocaine poisoning
- 3- methylene blue for cyanide poisoning
- 4- N-acetylcysteine in paraquat poisoning
- 5- pralidoxime in sarin (nerve gas) poisoning

Answer & Comments

Answer: 5- pralidoxime in sarin (nerve gas) poisoning

Sarin is an organophosphorus. Pralidoxime reactivates acetyl cholinesterase enzyme. Should be used in the first few hours.

Ethanol reduces the formation of toxic metabolites produced after ingestion of methanol and ethylene glycol, but not isopropyl alcohol. Glucagon is used in symptomatic β -blocker overdose. N-acetylcysteine is used in paracetamol overdose. Methylene blue is the antidote for serious methaemoglobinemia.

[Q: 384] OnExamination -
Emergency medicine

You have been called to the ward by the senior nurse, to review a repeat Calcium result. The repeat result is 3.9 mmol/l (2.2 - 2.6), the previous result 4 hours earlier was 3.2. The patient has a disseminated malignancy with an unknown primary.

Which of the following statements is most correct when considering the hypercalcaemia of malignancy?

- 1- NSAIDs are indicated for bone pain in this patient
- 2- Bisphosphonates inhibit osteoblast function thereby lowering calcium

- 3- A prolonged QT interval is associated with hypercalcaemia
- 4- On neurological examination, hyporeflexia may be exhibited
- 5- Calcitonin is of greater benefit than bisphosphonates in the treatment of hypercalcaemia of malignancy

Answer & Comments

Answer: 4- On neurological examination, hyporeflexia may be exhibited

This is an oncological emergency. Hyporeflexia is a common clinical sign in patients with hypercalcaemia. NSAIDs should not be prescribed in patients with hypercalcaemia, as they reduce renal blood flow, thus inhibiting urinary calcium excretion. Bisphosphonates inhibit bone resorption by osteoclasts, and are the first line pharmacological treatment of hypercalcaemia of malignancy, calcitonin use limited by its association with anaphylaxis. ECG changes in hypercalcaemia include bradycardia, prolonged PR, short QT, widened T waves and arrhythmia

[Q: 385] OnExamination -
Emergency medicine

A 64-year-old woman presented 10 hours after ingestion of 12g of Quinine Sulphate.

Which of the following is the most common characteristic clinical feature in this situation?

- 1- Blindness
- 2- Bradycardia
- 3- Hyperacusis
- 4- Hyperglycaemia
- 5- Hypotension

Answer & Comments

Answer: 1- Blindness

A tachycardia is seen in overdose, not a bradycardia. Quinine may cause tinnitus and

deafness, but not hyperacusis. Blindness is a characteristic feature of quinine overdose. Blurred vision may proceed to complete blindness within a few hours.

As vision is lost the pupils become dilated and unresponsive to light. Initially only narrowing of the retinal arterioles may be seen on fundoscopy but after 3 days retinal oedema may appear.

Hypotension may be a feature, especially in the context of dysrhythmia, but I feel that blindness is the "common characteristic feature".

[Q: 386] OnExamination -
Emergency medicine

A 40 year-old man suffers an intracerebral infarction.

Which of the following features in this patient would not be considered as a risk factor for his stroke?

- 1- Blood Pressure 156/72 mmHg
- 2- Cocaine use
- 3- Mitral valve prolapse
- 4- Plasma cholesterol of 6.5 mmol/l
- 5- Smoker of 5 cigarettes per day

Answer & Comments

Answer: 4- Plasma cholesterol of 6.5 mmol/l

Unlike IHD/MI, epidemiological studies do not show an increased risk of stroke associated with hypercholesterolaemia. This contrasts markedly with the risk reduction in stroke associated with statin therapy which suggests that statins reduce stroke through a mechanism independent of cholesterol. Other risk factors for stroke include Isolated systolic hypertension in particular. A previous history of DVT may suggest a coagulation disorder. The remaining stems are all associated with increased risk of intracerebral haemorrhage.

[Q: 387] OnExamination -
Emergency medicine

A 76-year-old woman is admitted with right pleuritic chest pain and breathlessness. She had surgery 2 months previously for fracture of right femur following a fall. She has a pyrexia of 38°C. Her CXR shows a little right basal shadowing. Her serum D-dimers are normal at 120.

White cell count is $14 \times 10^9/L$.

What is the most appropriate next step?

- 1- Blood cultures
- 2- Blood gases
- 3- Spiral CT chest
- 4- Start intravenous antibiotics
- 5- Ventilation-perfusion scan

Answer & Comments

Answer: 4- Start intravenous antibiotics

Although it is not specific for PE, normal D-dimers have a high negative predictive potential and would argue very much against there being a thromboembolic event. Thus, the suggestion is that this patient has a chest infection and hence appropriate antibiotic therapy is required. It could be argued that the other options of ABGs and Blood cultures are appropriate answers for this question. But, blood culture yields from chest infection would be low (although they are recommended in patients admitted to hospital) and arguably we could get as much information from sats as from ABGs. Also as both these options are given they kind of cancel each other out as appropriate choices. Therefore, the author of this question probably wants you to be able to differentiate between PE and pneumonia. Thus, the best answer would probably be treat with antibiotics.

[Q: 388] OnExamination -
Emergency medicine

In most cardiac arrest situations 1mg of adrenaline (epinephrine) is given intravenously every 3 minutes.

What is the correct volume and concentration of the adrenaline?

- 1- 0.1ml of 1 in 100
- 2- 1ml of 1 in 1000
- 3- 10ml of 1 in 1000
- 4- 1ml of 1 in 10,000
- 5- 10ml of 1 in 10,000

Answer & Comments

Answer: 5- 10ml of 1 in 10,000

A 1mg dose of adrenaline (epinephrine) would be administered with answers A, B and E. However, 10 ml of 1 in 10,000 is the recommended dose and concentration and is considered the optimum volume of adrenaline during cardiac arrest, and is recommended by the UK Research Council.

[Q: 389] OnExamination -
Emergency medicine

A 22-year-old female is admitted very distressed and short of breath. Examination reveals a respiratory rate of 35/min, a pulse of 120 beats per min, a blood pressure 110/70 mmHg, oxygen saturations of 90% and a Peak Expiratory Flow rate < 50% predicted. The Emergency Medical Services have administered salbutamol 5mg (twice) and face mask oxygen.

Which of the following is the most appropriate next action in this patient?

- 1- Arterial blood gas analysis
- 2- Intensive care referral
- 3- Oxygen 35%
- 4- Prednisolone 40mg

- 5- Salbutamol 5mg and ipratropium bromide 0.5mg

Answer & Comments

Answer: 5- Salbutamol 5mg and ipratropium bromide 0.5mg

According to British Thoracic Society guidelines addition of ipratropium would be the next step in the case of this lady with acute severe asthma. Prednisolone would be administered shortly thereafter. 35% oxygen is inadequate and a maximal concentration should be used. A blood gas is not essential for management particularly with the oxygen saturations of 90% although these will be performed. Intensive care referral may well be appropriate if this lady does not improve.

[Q: 390] OnExamination -
Emergency medicine

A 25-year-old is admitted on the medical intake. She is 10 weeks post partum and has been generally unwell for 2 weeks with malaise sweats and anxiety. On examination she is haemodynamically stable, and clinically euthyroid. TFTs show the following:

Free T₄ 33 pmol/L (9-23)
Free T₃ 8 nmol/L (3.5-6)
TSH <0.02 mU/L (0.5-5)

What is the appropriate management?

- 1- Carbimazole 40mg/day
- 2- Lugol's Iodine
- 3- Propranolol 20mg tds
- 4- Propylthiouracil 50mg/tds
- 5- Radioactive iodine therapy

Answer & Comments

Answer: 3- Propranolol 20mg tds

The diagnosis here is likely to be post partum thyroiditis which tends to occur within the 3 months of delivery followed by a hypothyroid

phase at 3-6 months, followed by spontaneous recovery in one third of cases. In the remaining two-thirds, a single-phase pattern or the reverse occurs. Management is centred on symptomatic treatment using β -blockers for relief of tremor or anxiety, and observation for the development of persistent hypo- or hyperthyroidism.

[Q: 391] OnExamination -
Emergency medicine

A 52 year-old male is admitted with haematemesis and melaena. Examination reveals that he is icteric, confused with a flapping tremor, has signs of chronic liver disease, a pulse rate of 110 bpm and blood pressure of 100/70 mmHg. Abdominal examination reveals ascites. An urgent endoscopy reveals small oesophageal varices, without evidence of bleeding but an oozing portal hypertensive gastropathy.

Which of the following measures would be the most appropriate treatment for this patient?

- 1- endoscopic banding
- 2- endoscopic injection of adrenaline
- 3- endoscopic injection of ethanolamine
- 4- oral propranolol
- 5- intravenous vitamin K

Answer & Comments

Answer: 2- endoscopic injection of adrenaline

The endoscopy shows small varices with no evidence of bleeding but diffuse oozing of blood. Hence endoscopic measures like banding for small varices will not be useful. There is probably no evidence that vit K is helpful as the coagulation is already likely to be deranged. Oral propranolol is useful as a later prophylaxis of variceal bleed.

[Q: 392] OnExamination -
Emergency medicine

An 80-year-old male presented with acute right-sided weakness. Examination revealed minimal right facial weakness, impaired elevation of the right shoulder, with relatively preserved right hand strength. There was global weakness in the right leg which appeared to be maximal in the foot.

Which of the following arteries is most likely to have been affected?

- 1- Anterior cerebral artery
- 2- Lenticulostriate artery
- 3- Middle cerebral artery
- 4- Posterior cerebral artery
- 5- Posterior communicating artery

Answer & Comments

Answer: 1- Anterior cerebral artery

Unilateral occlusion (distal to Ant. Comm. origin) of Anterior Cerebral Artery produces contralateral sensorimotor deficits mainly involving the lower extremity with sparing of face and hands (think of the humunculus).

The Lateral Lenticulostriate artery is a branch of the middle cerebral artery. Occlusion causes damage to the internal capsule resulting in contralateral hemiparesis and sensory deficit. Speech may be affected (medial temporal lobe) as well as visual function (Meyer's loop: optic radiations affected).

Middle Cerebral Artery: Occlusion at the stem (proximal segment) results in:

- " Contralateral hemiplegia affecting face, arm, and leg (lesser).
- " Homonymous hemianopia - Ipsilateral head/eye deviation.
- " If on left: global aphasia.

Posterior cerebral artery: A variety of neurological syndromes including:-

- " Pure hemisensory loss
- " visual field loss- a variety
- " Visual agnosia
- " Disorders of reading (alexia, dyslexia) and more.....

[Q: 393] OnExamination -
Emergency medicine

Which of the following reactions is involved in the metabolism of paracetamol under normal conditions?

- 1- cytochrome p450 dependent oxidation
- 2- hydrolysis
- 3- conjugation to glucuronic acid
- 4- conjugation to glutathione
- 5- acetylation

Answer & Comments

Answer: 3- conjugation to glucuronic acid

Paracetamol is conjugated to glucuronic acid and sulphate under normal conditions. In overdose these processes become saturated and the drug is then conjugated with glutathione. If the glutathione supply is depleted then a toxic metabolite is formed.

[Q: 394] OnExamination -
Emergency medicine

Which of the following percentages most accurately reflects the mortality associated with the modern management of diabetic ketoacidosis?

- 1- 0.5%
- 2- 1%
- 3- 2-3%
- 4- 5-6%
- 5- 8-10%

Answer & Comments

Answer: 3- 2-3%

Despite the advances in the management of diabetes in general and the improvements in intensive care, studies reveal that the mortality associated with diabetic ketoacidosis remains stubbornly around the 2-5% since the 1970s. Specifically mortality relates to cerebral oedema.

[Q: 395] OnExamination -
Emergency medicine

A 17-year-old girl presents after having ingested fifty of her mother's Fluoxetine tablets, approximately 5 hours previously.

Which one of the following clinical features is compatible with this history?

- 1- Pupillary constriction
- 2- heart rate of 60 beats per minute
- 3- QRS duration of 120 ms (<100)
- 4- respiratory rate of six breaths per minute
- 5- convulsions

Answer & Comments

Answer: 2- heart rate of 60 beats per minute

Unlike the Tricyclic antidepressants, Fluoxetine like many of the SSRIs are safe in overdose causing very few effects. Rarely, reports would suggest that tachycardia can occur together with tremor, drowsiness, nausea and vomiting. Thus, this is a bit of a trick question as normal observations would be expected and so, a heart rate of 60 beats per minute is compatible with the patient having taken an overdose of Prozac. Pupillary constriction suggests opiates as does respiratory depression with prolonged QRS with TCAs.

[Q: 396] OnExamination -
Emergency medicine

A 22-year-old male is admitted wheezing with a respiratory rate of 35/min, a pulse of 120 beats per min, blood pressure 110/70 mmHG, Peak Expiratory Flow rate < 50% predicted. The Emergency Medical Services have administered salbutamol 5mg (twice), Ipratropium 0.5mg and face mask oxygen. His arterial blood gas reveals:

pH 7.42 (7.35-7.45)

paCO₂ 5.0 kPa (4.5-5.9)

paO₂ 22 kPa (10.5-13.2kPa)

Base excess -2

SpO₂ 98

Which of the following is the most appropriate action for this man?

- 1- Chest X-ray
- 2- Intensive care referral
- 3- Ipratropium
- 4- Magnesium 1-2 g
- 5- Oxygen 35 %

Answer & Comments

Answer: 2- Intensive care referral

In this case the patient is showing signs of respiratory decompensation. A normal or raised PaCO₂ in an asthmatic is a warning of impending respiratory failure as the patient becomes too tired to ventilate adequately and ITU need to be notified. Administration of magnesium would be the next therapeutic measure. A chest x-ray will be helpful but should not delay in treatment and referral. 35 % oxygen is inadequate.

[Q: 397] OnExamination -
Emergency medicine

A 70-year-old male presents with haematemesis and malaena. His presenting blood pressure is 80/46 mmHg, with a heart

rate of 114 bpm. He is known to have idiopathic cirrhosis, and there is mild encephalopathy. You fluid resuscitate him with colloid, blood, FFP and dextrose.

Which of the following is the next best step in management?

- 1- Ciproflaxacin
- 2- Oral beta-blockers
- 3- OGD
- 4- Glypressin
- 5- Lactulose

Answer & Comments

Answer: 4- Glypressin

Glypressin causes splanchnic vasoconstriction thereby restricting bleeding from varices, which is the likely cause of bleeding in this patient. In the acute GI bleed described above, glypressin is the best treatment to aid cardiovascular resuscitation. Beta-blockade comes into play later in order to treat portal hypertension chronically. Lactulose should be considered to guard against progression of encephalopathy. OGD should be considered, but full resuscitation and optimal medical management should be attempted in the first instance. In the event of ascites, ciprofloxacin is used as prophylaxis against spontaneous bacterial peritonitis. This is of secondary importance here.

[Q: 398] OnExamination -
Emergency medicine

A 63-year-old female presents with a one day history of confusion with headaches. On examination she is confused, with a Glasgow Coma Scale of 13 and a temperature of 39.5°C. She has nuchal rigidity and photophobia. CSF examination reveals a glucose of 0.5 mmol/l, a white cell count of 2500 per mm and Gram positive Cocci in pairs.

Which of the following is correct?

- 1- The most likely infective organism is *Staphylococcus aureus*
- 2- The organism is likely to be penicillin resistant.
- 3- Rifampicin should be given to close contacts.
- 4- Nerve deafness would be a common complication in this case.
- 5- A characteristic rash would be expected.

Answer & Comments

Answer: 4- Nerve deafness would be a common complication in this case.

This patient has pneumococcal meningitis, caused by the Gram positive coccus *Strep Pneumonia*. This is the second commonest cause of bacterial meningitis (commonest in the elderly) and is associated with the highest mortality (20%) and highest morbidity, such as deafness which may occur in 50%. Contacts do not require treatment and there is no rash associated with pneumococcal meningitis. *Meningococcus* is gram negative.

[Q: 399] OnExamination -
Emergency medicine

Which of the following features would be expected in acute tubular necrosis?

- 1- Heavy proteinuria on urinalysis
- 2- Red cell casts on urinalysis
- 3- Urine plasma osmolality ratio is more than 1:1
- 4- Urinary sodium concentration greater than 30 mmol/l
- 5- Creatinine clearance would be expected to be normal 1 year after the initial insult.

Answer & Comments

Answer: 4- Urinary sodium concentration greater than 30 mmol/l

Proteinuria usually mild is common with granular casts found on urinalysis. The urine sodium concentration is typically above 30 mmol/l and osmolality ratio <1:1. Red cell casts suggest nephritis and normalisation of the creatinine clearance occurs in only 40% of cases one year later.

[Q: 400] OnExamination -
Emergency medicine

A 24-year-old man presents to the Accident & Emergency department and complains of shortness of breath. Before his Chest X-ray is taken he tells the casualty officer that he is known to have an 'azygous lobe'.

What region of the Chest X-ray would expect to see an 'azygous lobe'?

- 1- left lower zone
- 2- left mid zone
- 3- left upper zone
- 4- right lower zone
- 5- right upper zone

Answer & Comments

Answer: 5- right upper zone

An azygous lobe is seen in about 0.5% of routine Chest X-rays and is a normal variant. It is seen as a 'reverse comma sign' behind the medial end of the right clavicle.

[Q: 401] OnExamination -
Emergency medicine

In malignant hyperpyrexia:

- 1- A mortality rate of 20% may be expected
- 2- Elevation of serum creatine kinase and myoglobinuria is diagnostic
- 3- Muscle biopsy may be histologically normal
- 4- The only available specific treatment is sodium dantrolene, which has a neutral pH
- 5- The predisposing gene is thought to be on chromosome 9

Answer & Comments

Answer: 3- Muscle biopsy may be histologically normal

Malignant hyperpyrexia (MH) is characterised by increased temperature and muscle rigidity during anaesthesia, which results from abnormal skeletal muscle contraction and increased metabolism. The predisposing gene is thought to be on chromosome 19, close to the gene for the ryanodine / dihydropyridine receptor complex. Known triggering agents include the volatile anaesthetic agents and suxamethonium. Patients show different sensitivity to the triggering agents and the reaction can be delayed by several hours. Intravenous dantrolene (up to 10mg/Kg) is the only available specific treatment. The solution has a pH of 9 to 10. The prognosis is good when the appropriate treatment is instigated early, mortality being <5% (prior to dantrolene the mortality was 80%). Serum creatine kinase elevation and myoglobinuria are suggestive but not diagnostic of MH. Myoglobin and creatine kinase are both known to increase after giving suxamethonium to normal patients. Contracture tests using caffeine and halothane are the investigations of choice. Muscle biopsies may appear histologically normal.

[Q: 402] OnExamination -
Emergency medicine

A 17-year-old woman presented 6 hours after taking 30g of Paracetamol.

Which of the following factors is most likely to predict an increased risk of hepatotoxicity from the Paracetamol?

- 1- Anorexia nervosa
- 2- Consumption of 20 units of alcohol since taking the Paracetamol
- 3- Gilbert's disease
- 4- Ingestion of Amitriptyline with the Paracetamol

5- Smoking 20 cigarettes per day

Answer & Comments

Answer: 1- Anorexia nervosa

High risk groups in paracetamol overdose include malnourished patients (anorexia nervosa/bulimia nervosa), patients taking enzyme inducing drugs (eg carbamazepine, phenytoin rifampicin and St John's Wort), patients with induced liver enzymes due to chronic ethanol abuse and HIV positive patients. See review in Clinical Medicine Vol 3 No 2 2003.

[Q: 403] OnExamination -
Emergency medicine

A 30-year-old man presents to the Accident and Emergency Department with a history of drug overdose. He is known to be repeatedly admitted with similar episodes of self-harm. On this occasion he is drowsy and has prominent hypersalivation.

Which of the following agents, found on his person, is the likely cause?

- 1- Chlormethiazole
- 2- Cocaine
- 3- Dosulepin
- 4- L-dopa
- 5- Solvent cannister

Answer & Comments

Answer: 1- Chlormethiazole

Hypersalivation is seen with parasympathomimetic agents, insecticides, arsenic, strychnine, chlormethiazole and clozapine and others. Solvent abuse may cause an acneiform rash around the buccal cavity. Cocaine abuse leads to hypertension and nasal septum perforation. The other agents are anticholinergic and would cause dry mouth in overdose.

[Q: 404] OnExamination -
Emergency medicine

A 27-year-old lady collapses in the Emergency Room after being admitted with numerous seizures. You obtain information from her husband that she has a past history of seizures but has not had any of the last two years and is well controlled on valproate. He also informs you that she has been gaining weight recently and has also had erratic menses which the neurology clinic attribute to the valproate.

Her pulse is 110/min, blood pressure is 160/90 mmHg and her urinalysis reveals 3+ proteinuria.

After Airway, Breathing and circulation, the immediate drug therapy should be:

- 1- Diazepam 10mg
- 2- Lorazepam 2mg
- 3- Magnesium 2 grams
- 4- Nil
- 5- Phenytoin 1000mg

Answer & Comments

Answer: 3- Magnesium 2 grams

This lady may well be having an epileptic fit, but why should a young woman have an elevated BP and proteinuria? In a woman of this age with raised blood pressure and proteinuria, a diagnosis of eclampsia has to be considered and the primary treatment of eclampsia is the administration of magnesium.

[Q: 405] OnExamination -
Emergency medicine

An 18 year-old woman presents thirty hours after taking about 50 Paracetamol tablets (25g).

Which of the following tests measured at this time point would be most helpful in determining the outcome?

- 1- ALT concentration

- 2- Bilirubin concentration
- 3- Creatinine concentration
- 4- Paracetamol concentration
- 5- prothrombin time

Answer & Comments

Answer: 1- ALT concentration

The patient has ingested a seriously toxic dose of paracetamol. The best determinant of this risk at thirty hours would be ALT indicating hepatic damage which would be expected prior to alteration in prothrombin time. Paracetamol concentrations would be rather meaningless at this time point and irrespective she would be treated with activated charcoal and N-acetylcysteine.

There are four phases of paracetamol overdose

* Phase 1 (0-24 h) o Asymptomatic o Anorexia o Nausea or vomiting o Malaise o Subclinical rise in serum AST - 12 hours postingestion

* Phase 2 (18-72 h) o Right upper quadrant abdominal pain, anorexia, nausea, vomiting o Continued rise in serum transaminases levels (note this is the time slot for our patient with the ALT rises)

* Phase 3 (72-96 h) o Centrilobular hepatic necrosis with continued abdominal pain o Jaundice o Coagulopathy o Hepatic encephalopathy o Nausea and vomiting o Renal failure o Fatality Rising INR/PT from 3 days.

* Phase 4 (4 d to 3 wk) o Complete resolution of symptoms o Complete resolution of organ failure

[Q: 406] OnExamination -
Emergency medicine

These are the blood gas results obtained from a 20-year-old female admitted to hospital.

hydrogen ion concentration 35 nmol/L (35-45)

pH 7.45 (7.35-7.45)
 pCO₂ 6.8 kPa (4.6-5.9)
 bicarbonate 32 mmol/L (22 - 26)

Which of the following is the most likely cause of this patient's acid-base derangement?

- 1- Amitriptyline overdose
- 2- Cushing's syndrome
- 3- Hepatic failure
- 4- Pregnancy
- 5- Salicylate poisoning

Answer & Comments

Answer: 4- Pregnancy

This patient has a mild metabolic alkalosis with what appears to be respiratory compensation as reflected by the elevated pCO₂. Amitriptyline overdose is associated with acidosis as is salicylate poisoning. Hepatic failure usually presents with acidosis. This type of picture is associated with prolonged vomiting (as in pregnancy), diarrhoea, diuretic therapy and in Cushing's syndrome or in those receiving high dose corticosteroids. With no other information provided for this case, common things being common, one should select pregnancy as the best answer for a 20-year-old female.

[Q: 407] OnExamination -
Emergency medicine

An 18-year-old female presents with an acute exacerbation of asthma associated with a chest infection. She is unable to complete a sentence and her peak flow rate was 35% of her normal level. She is treated with high flow oxygen, nebulised bronchodilators and oral steroids but this is associated with little change in her condition.

Which of the following treatments, given intravenously, would be the most appropriate for this patient?

- 1- Aminophylline

- 2- Augmentin
- 3- Hydrocortisone
- 4- Magnesium
- 5- Salbutamol

Answer & Comments

Answer: 4- Magnesium

This patient has acute severe asthma (PEFR 33-50% predicted/best, unable to complete sentences in one breath, respiratory rate > 25 breaths/min, pulse rate > 110 beats/minute). She has not responded to initial treatment and the treatment of choice now is intravenous magnesium 1.2-2g over 20 minutes. [see: BTS guidelines on the Management of Asthma . Thorax 2003;58 (suppl 1). OR www.sign.ac.uk]

[Q: 408] OnExamination -
Emergency medicine

A 52-year-old woman presents with left loin pain. Past history included hypertension and progressive cognitive decline. On examination she was pyrexial, had livedo reticularis and a blood pressure of 180/100 mmHg.

Examination of the abdomen revealed no masses but there was tenderness in the left flank.

Investigations revealed:

haemoglobin 12.9 g/dL (11.5-16.5)
 white cell count $8.7 \times 10^9/L$ (4-11)
 platelet count $83 \times 10^9/L$ (150-400)
 serum creatinine 106 $\mu\text{mol/L}$ (60-110)
 urine dipstick analysis:
 " blood+++
 " protein+

Which one of the following tests is most likely to be positive?

- 1- anticardiolipin antibody

- 2- antiglomerular basement membrane antibody
- 3- antimitochondrial antibody
- 4- antineutrophil cytoplasmic antibody
- 5- antistreptolysin O antibody

Answer & Comments

Answer: 1- anticardiolipin antibody

This patient has features of to suggest SLE with antiphospholipid syndrome with this presentation possibly due to renal vein thrombosis (flank pain with blood and protein in urine). The diagnosis would be supported by the thrombocytopaenia, history of hypertension and the livedo reticularis. Wegner's with positive ANCA would be a less likely diagnosis. Read more about antiphospholipid syndrome.

[Q: 409] OnExamination -
Emergency medicine

A 58-year-old man presents with a month history of breathlessness. He was a non-smoker. On examination, his temperature was 36.7°C, with a respiratory rate of 20 breaths per minute and normal breath sounds to auscultation and a pulse of 92 bpm. Arterial blood gases on air showed:

pH 7.51 (7.36 - 7.44)

pO₂ 8.4 kPa (11.3 - 12.6)

pCO₂ 4.0 kPa (4.7 - 6.0)

What is the most likely diagnosis?

- 1- atypical pneumonia
- 2- fibrosing alveolitis
- 3- hysterical hyperventilation
- 4- inhaled foreign body
- 5- pulmonary thromboembolism

Answer & Comments

Answer: 5- pulmonary thromboembolism

This patient has a respiratory alkalosis with type 1 respiratory failure as evidenced by low pO₂ and low pCO₂. Chronic venous thromboembolism would be the most likely explanation for this man's presentation. Hyperventilation would be excluded by the type 1 respiratory failure, an inhaled foreign body would not produce such a picture and an atypical pneumonia would be associated with pyrexia and some clinical signs. The differential diagnosis here is pulmonary fibrosis but basal crackles may be expected and the history is somewhat short.

[Q: 410] OnExamination -
Emergency medicine

A 17-year-old male presents to A+E after an overdose of alcohol and paracetamol. He complained of abdominal discomfort and an intravenous infusion of N-Acetylcysteine was commenced. *15 minutes later he developed breathlessness, reported feeling flushed and developed a tachycardia.*

- 1- A disulfiram-like (antabuse) reaction has occurred
- 2- The patient has had a panic attack
- 3- The patient has developed pulmonary oedema
- 4- The patient has received an overdose of N-Acetylcysteine
- 5- The patient has received N-Acetylcysteine previously

Answer & Comments

Answer: 5- The patient has received N-Acetylcysteine previously

This patient is having an acute hypersensitivity reaction the most common, dose independent adverse drug reaction. It is caused by previous exposure and being sensitised to the drug. The initial exposure induces the production of antibodies of Ig E class, subsequent exposure induces an immunological reaction

hypoxylaxis. Some drugs can produce an similar pseudoallergic reaction on first exposure.

[Q: 411] OnExamination -
Emergency medicine

A 19-year-old woman became breathless while travelling on an aeroplane.

Which one of the following features most strongly supports a diagnosis of acute hyperventilation related to a panic disorder?

- 1- Carpal spasm.
- 2- Finger paraesthesiae.
- 3- Hypotension.
- 4- Light-headedness.
- 5- Loss of consciousness

Answer & Comments

Answer: 1- Carpal spasm.

We need to distinguish between the signs that may be expected in the tachypnoea associated with the hypoxia from a PE or any other serious respiratory problem and the hyperventilation with increased pO₂ in a panic attack. A carpal spasm would be most likely to reflect this. Finger paraesthesiae can occur with PE, as can hypotension, light-headedness and loss of consciousness. Carpal spasm is found in association with hyperventilation due to the respiratory alkalosis which results in a reduction in ionised calcium concentration.

[Q: 412] OnExamination -
Emergency medicine

A 28-year-old female, three days post-partum develops severe headache associated with seizures. During her pregnancy her blood pressure had been mildly elevated in the third trimester. On examination, she had a GCS of 15 but was slightly confused and drowsy. Her temperature was 37.5°C, she had mild nuchal

rigidity but neurological examination was otherwise normal.

What is the most likely diagnosis?

- 1- Bacterial meningitis
- 2- Cortical vein thrombosis
- 3- Eclampsia
- 4- Intracerebral haemorrhage
- 5- Subarachnoid haemorrhage

Answer & Comments

Answer: 2- Cortical vein thrombosis

Post-partum period is a risk factor of cortical vein and sinus thrombosis. It typically presents with headache, seizures and focal neurological deficit 2-3 weeks postpartum (but is also seen earlier). Other clinical presentations include a BIH type of picture (papilloedema, visual disturbances and headaches) or a subacute encephalopathic picture. Thrombophilia screen should be performed. Eclampsia typically improves following delivery. The seizures can occur prepartum, intrapartum, or postpartum. If the seizure occurs postpartum, it usually occurs within the first 24 hours after delivery.

[Q: 413] OnExamination -
Emergency medicine

A 78-year-old male is brought to A+E and has a witnessed seizure in the resuscitation room. His blood glucose is recorded as 1.0mmol/l. He is not diabetic, and has no other significant past medical history. He is given 50ml of 50% dextrose and he slowly recovers over the next 1 hour. A serum cortisol concentration later returns as 800nmol/l (120-600).

Which of the following would be the most relevant investigation for this man?

- 1- Chest x-ray
- 2- CT head scan
- 3- Electrocardiogram

4- Prolonged 72 hour fast

5- Short synacthen test

Answer & Comments

Answer: 4- Prolonged 72 hour fast

The historical and biochemical evidence here suggests a diagnosis of spontaneous hypoglycaemia and the most likely cause would be an insulinoma. However, one would wish to exclude possible drug administration and although not mentioned here, a sulphonylurea screen should be undertaken. He has presented with symptomatic hypoglycaemia, is not diabetic therefore should not have received insulin or a sulphonylurea. There is nothing to suggest alcohol or drug misuse. Similarly, there is nothing to suggest sepsis. However, to prove a diagnosis of spontaneous hypoglycaemia a prolonged fast is required and should be develop hypoglycaemia, measurement of insulin and C-peptide will be needed to confirm the diagnosis. The appropriate cortisol response during his hypoglycaemic episode (cortisol 800) excludes hypoadrenalism.

[Q: 414] OnExamination -
Emergency medicine

A 30-year-old man is admitted three hours after taking an overdose of amitriptyline and diazepam. On examination he was drowsy with a Glasgow Coma Scale of 8, he had a pulse of 140 beats per minute, a blood pressure of 114/88 mmHg and dilated pupils. His oxygen saturation was 90% on room air.

What is the most appropriate initial action for this patient?

- 1- activated charcoal
- 2- CT head scan
- 3- ECG
- 4- IV atenolol
- 5- IV flumazenil

Answer & Comments

Answer: 3- ECG

Daft question really. The most appropriate initial action would be to get the investigations done as quickly as possible ?arterial blood gases and ECG as the latter may show QRS widening and merit treatment. Then, the next step would be gastric decontamination with lavage and activated charcoal. Treatment with bicarbonate is also advocated as this patient displays features of severe TCA overdose. He doesn't need a CT scan as the symptoms are typical of tricyclic overdose. Flumazenil is not appropriate for this patient as the symptoms are mostly of TCA overdose nor is IV atenolol appropriate for the arrhythmias ?bretylium, phenytoin or lidocaine.

[Q: 415] OnExamination -
Emergency medicine

A 41-year-old female is brought into A&E after taking an uncertain quantity of paracetamol two hours previously and trying to hang herself. She becomes agitated and insists that she wants to go home immediately. You judge that she is at high risk of suicide.

Which of the following is the most appropriate course of action for this patient?

- 1- Call the duty psychiatrist, and with other staff in the A&E department attempt to restrain her under Common Law until they arrive.
- 2- Ask her to sign a 'discharge against medical advice' form and let her go.
- 3- Call the duty psychiatrist, but let the patient go if she insists and the duty psychiatrist does not arrive in time to see her.
- 4- Detain her under section 5(2) of the Mental Health Act.
- 5- Call the hospital security services, restrain her and sedate her.

Answer & Comments

Answer: 1- Call the duty psychiatrist, and with other staff in the A&E department attempt to restrain her under Common Law until they arrive.

In an A&E department the suicidal patient who declines to be admitted for observation and treatment should be managed as follows:

- Ensure that a member of staff stays with them at all times
- Call the duty psychiatrist
- If they attempt to abscond before or during psychiatric assessment, the staff of the A&E department have a duty under Common Law to restrain the patient. If a patient who is already being nursed on medical, surgical or obstetric ward, or in a high dependency or intensive care unit, develops a mental illness (or has an exacerbation of a pre-existing disorder), their physician or surgeon can authorise their compulsory detention for up to 72 hours under section 5(2) of the Mental Health Act.

[Q: 416] OnExamination -
Emergency medicine

A 65-year-old man is admitted from home with a community acquired pneumonia. He has a history of skin rash to Penicillin documented in his medical notes. He has adverse prognostic features and a CURB score of 4.

What would be an appropriate empirical antibiotic choice?

- 1- Augmentin and Clarithromycin
- 2- Augmentin and Gentamycin
- 3- Cefotaxime and Erythromycin
- 4- Cefuroxime and Metronidazole
- 5- Ciprofloxacin and Clarithromycin

Answer & Comments

Answer: 3- Cefotaxime and Erythromycin

Community acquired pneumonia is most commonly caused by strep pneumonia, hence, the use of a beta lactam antibiotic because of the increased incidence of atypical organismc such as mycoplasma. A macrolide such as Erythromycin is also recommended. Augmentin is contraindicated as it is Penicillin based. Ciprofloxacin has poor cover against strep pneumonia and Metronidazole is used for anaerobic infections.

The issue of cross-reactivity of hypersensitivity reactions between beta-lactam antibiotics is a concern and isn't fully addressed in the British Thoracic Society guidelines for CAP of 2001 or the update in 2004 for severe hospitalised CAP. They state that alternatives would be a macrolide for non-severe CAP or levofloxacin or possibly moxifloxacin (but in combination with benzylpenicillin in severe cases). The difficulty with the BTS guidelines is that a lot of the available evidence is of a very low level such as consensus view rather than randomised controlled trials. An interesting article in the NEJM discusses more generally the topic of cephalosporin cross-reactivity. NEJM 2001;345(11):804-809.

In this case a credible alternative for beta-lactam sensitivity is not mentioned and the best choice, because of clinical necessity since severe pneumonia can be fatal if treated with antibiotics that are not effective, is to go with the only cephalosporin and macrolide combination that is offered.

[Q: 417] OnExamination -
Emergency medicine

A 54-year old woman was admitted with acute breathlessness. On examination she had a temperature of 37°C, a respiratory rate of 32 breaths per minute, a pulse of 120 beats per minute, a blood pressure of 100/60 mmHg, and a peak expiratory flow rate of 250 litres per minute. Auscultation of the heart and chest was normal. The Chest X-ray was normal and blood gases on air showed:

pH 7.35 (7.36 - 7.44)
 PaO₂ 6.0kPa (11.3 - 12.6)
 PaCO₂ 3.9 kPa (4.7 - 6.0)
 Serum bicarbonate 20 mmol/l (20 - 28)
 She was started on high flow oxygen.

What is the most important next treatment?

- 1- amoxicillin intravenously
- 2- aminophylline intravenously
- 3- intravenous fluids
- 4- low molecular weight heparin
- 5- nebulised salbutamol

Answer & Comments

Answer: 4- low molecular weight heparin

This patient has features of a Type 1 respiratory failure with mixed acid-base disturbances. The differential diagnosis here lies between PE and acute severe asthma. On the basis of the reasonable PEFR of 250, the tachycardia and hypotension, PE seems the most likely explanation and LMWH would be the treatment of choice.

IV fluids are potentially harmful since the cause of the shock is an obstructed right ventricle. Fluids may dilate the ventricle further and reduce cardiac output. There is a role for fluids in those patients with rapidly falling BP but this should preferably be done (if there is time) with central pressure monitoring.

[Q: 418] OnExamination -
Emergency medicine

A 50-year-old male presented with acute respiratory failure during an episode of acute pancreatitis and was thought to have developed adult respiratory distress syndrome (ARDS).

Which of the following would support a diagnosis of ARDS?

- 1- High pulmonary capillary wedge pressure
- 2- High protein pulmonary oedema
- 3- Hypercapnia
- 4- Increased lung compliance
- 5- Normal chest X-ray

Answer & Comments

Answer: 2- High protein pulmonary oedema

ARDS is characterised by hypoxaemia, reduced lung compliance, pulmonary hypertension and pulmonary infiltrates on the chest X-ray. There is damage to the capillary and endothelial cell linings resulting in oedema and leakage of proteins and cells into the interstitial and alveolar spaces at normal pulmonary capillary hydrostatic pressures. Wedge pressure unlike the high pressures seen with LVF and pulmonary oedema is often normal. Hypercapnia often a late feature of ARDS does not distinguish from any other cause of type 2 respiratory failure.

[Q: 419] OnExamination -
Emergency medicine

A 52-year-old schoolteacher attends with weight loss and sweats. She is clinically thyrotoxic with a diffuse goitre. Subsequent investigations show:

Free T₄ 40 pmol/L (9-23)
 Free T₃ 9.8 nmol/L (3.5-6)
 TSH 6.1 mU/L (0.5-5)

A repeat TFT is similar.

What is the most appropriate investigation for this patient?

- 1- FNA of thyroid gland
- 2- MRI scan pituitary gland
- 3- Radio-isotope uptake scan of thyroid gland
- 4- Repeat TFT checking for antibody interference
- 5- Thyroid auto antibodies

Answer & Comments

Answer: 2- MRI scan pituitary gland

This patient is thyrotoxic, however the non suppressed TSH suggests that this is due to excessive TSH production by the pituitary gland the possibility of a Thyrotroph adenoma must be pursued. In primary hyperthyroidism the TSH should always suppressed by negative feedback, which is NOT the case here. TSHomas are indeed very rare but the giveaway would be the normal or elevated TSH with thyrotoxicosis.

[Q: 420] OnExamination -
Emergency medicine

A 53-year-old man with a known history of Grave's disease presents to the Emergency department with palpitations, anxiety and fine tremor of both hands. ECG shows rapid atrial fibrillation with ventricular rate of 160 to 180/min. His blood pressure was 110/80 mmHg. TSH was 0.01 mIU/L (N0.17-4.2) and Free T₄ 60.3 pmol/L (N13-23).

What is the immediate management for this patient?

- 1- Carbimazole
- 2- DC cardioversion
- 3- Digoxin
- 4- Propranolol
- 5- Warfarin

Answer & Comments

Answer: 4- Propranolol

AF occurs in 10% to 25% of patients with hyperthyroidism, more commonly in men and the elderly than in women or patients less than 75 years old. In a patient with hyperthyroidism and AF, initial therapy should focus on ventricular rate control with β blockers but conversion to sinus rhythm frequently occurs spontaneously with treatment of hyperthyroidism. AF in

thyrotoxicosis is characterized by rapid ventricular response, typically resistant to Digoxin therapy. Electric or pharmacologic cardioversion should be attempted only in euthyroid patients who are haemodynamically unstable. If AF persists, consideration should be given to anticoagulation in patients who are at risk of embolic events.

[Q: 421] OnExamination -
Emergency medicine

A 16-year-old girl with obesity was referred with abdominal swelling and mild ankle oedema. On examination the blood pressure was 140/90 mmHg. Investigations revealed: Haemoglobin 10.5g/dL (11.5-16.5), Serum biochemistry normal, Serum albumin 34 g/L (37-49), Urine dipstick proteinuria +

Which is the most appropriate investigation that you would request next for this patient?

- 1- 24 hour urinary protein estimation.
- 2- Abdominal ultrasound.
- 3- Plasma protein electrophoresis.
- 4- Urinary albumin: creatinine ratio.
- 5- Urinary B-human chorionic gonadotrophin test (B-HCG)

Answer & Comments

Answer: 5- Urinary B-human chorionic gonadotrophin test (B-HCG)

This young girl has been 'gaining weight', has abdominal swelling and ankle oedema. She is hypertensive and has a mild anaemia with proteinuria. These signs should 'ring a bell' suggesting a concealed pregnancy with pre-eclampsia. The most relevant investigation would be a pregnancy test ?urinary B-HCG.

[Q: 422] OnExamination -
Emergency medicine

A 45-year-old male with a long history of alcohol abuse presents with a two day history

of deteriorating confusion. On examination he is drowsy, has a temperature of 39°C, a pulse of 110 beats per minute, a small amount of ascites and has features of a left side hemiparesis.

What is the most likely diagnosis?

- 1- Cerebral abscess
- 2- Cerebro-vascular accident
- 3- Hepatic encephalopathy
- 4- Wernicke's encephalopathy
- 5- Sub-dural haematoma

Answer & Comments

Answer: 1- Cerebral abscess

This man with chronic alcohol abuse now presents with a fever and left hemiparesis. The most likely diagnosis would therefore be cerebral abscess. The fever would not itself be explained by a subdural haematoma nor would a simple CVA explain this. Similarly, delirium tremens or encephalopathy would not be associated with the hemiparesis.

[Q: 423] OnExamination -
Emergency medicine

A 54-year-old male with Child's grade C hepatic encephalopathy presents with haemetemesis.

Which of the following is the most appropriate immediate therapy?

- 1- IV Desmopressin
- 2- IV Isoket
- 3- IV Omeprazole
- 4- IV Propranolol
- 5- IV Somatostatin

Answer & Comments

Answer: 5- IV Somatostatin

The answer here is octreotide/Somatostatin. Nitrates are never used as monotherapy but

used in conjunction with vasopressin not desmopressin. Propranolol is used only as prophylaxis and not in an emergency. Omeprazole is useful only in peptic ulcerations.

[Q: 424] OnExamination -
Emergency medicine

A 19-year-old female type 1 diabetic is admitted with diabetic ketoacidosis.

Which of the following is most appropriate concerning the use of a bicarbonate infusion?

- 1- No benefit from using a bicarbonate infusion.
- 2- Commence a bicarbonate infusion at pH less than 7.
- 3- Commence a bicarbonate infusion with a standard bicarbonate concentration below 5 mmol/l (NR 22-26).
- 4- Commence bicarbonate infusion with a potassium concentration above 6 mmol/l.
- 5- Commence a bicarbonate infusion with a ketone concentration above 5 mmol/l (NR less than 1)

Answer & Comments

Answer: 2- Commence a bicarbonate infusion at pH less than 7.

The use of bicarbonate in DKA is controversial. However, most authorities agree that a bicarbonate infusion may be used in subjects with a severe metabolic acidosis (pH less than 7).

[Q: 425] OnExamination -
Emergency medicine

A 42-year-old female presents following an episode of confusion associated with vomiting and abdominal pain. She had a one month history of weight loss and receives thyroxine for hypothyroidism which was diagnosed five years ago. On examination she appeared

unwell, with a temperature of 37.5°C and her blood pressure was 100/50 mmHg. Investigations revealed:

sodium	130 mmol/L (137-144)
potassium	4.8 mmol/L (3.5-4.9)
urea	7.6 mmol/L (2.5-7.5)
glucose	2.7 mmol/L (3.0-6.0)
freeT4	9 pmol/l (10-22)
TSH	1 mu/l (0.5-5)

Which one of the following given intravenously would be the most appropriate initial management?

- 1- Cefuroxime
- 2- 10% Dextrose infusion
- 3- Glucagon
- 4- Hydrocortisone
- 5- Tri-iodothyronine

Answer & Comments

Answer: 4- Hydrocortisone

This young female presents with classical features of Addison's disease and the most appropriate and life-saving therapy is steroids given intravenously. The abnormal TFTs are often encountered in association with acute hypoadrenalism. Giving thyroxine may actually exacerbate the condition.

[Q: 426] OnExamination -
Emergency medicine

A 31-year-old female with pulmonary hypertension complains of increasing shortness of breath. She is 36 weeks gestation in her first pregnancy.

Which of the following statements is correct?

- 1- Chest X-ray is contraindicated
- 2- Elevated D-dimers rule out PE
- 3- Enoxaparin dose should be halved in pregnancy

- 4- Nifedipine is contraindicated in pregnancy
- 5- Risk of maternal mortality in patients with pulmonary hypertension is 30%

Answer & Comments

Answer: 5- Risk of maternal mortality in patients with pulmonary hypertension is 30%

A chest X-ray is not contraindicated in pregnancy. Any pregnant female presenting with shortness of breath should be reviewed by a senior member of the obstetric team, advice which comes from the RCOG. Enoxaparin dose should be doubled in pregnancy, due to the increased GFR in pregnancy. D-dimers are always elevated in pregnancy, and are not helpful as a diagnostic aid, unless of course they are low (very unlikely), thereby making the clinical suspicion of PE low. Nifedipine is not contraindicated in pregnancy, but should be used judiciously. Labetalol and Methyldopa are the commonest antihypertensives used in pregnancy. Patients with pulmonary hypertension have a high mortality of at least 30% - some authors put it at 50% - seemingly highest immediately after delivery.

[Q: 427] OnExamination -
Emergency medicine

A patient has just received intravenous ceftazidime. They immediately become flushed and wheezy, with a blood pressure of 80/40 mmHg.

Which of the following is the most appropriate immediate management for this patient?

- 1- Chlorphenamine 10mg IV
- 2- Epinephrine 0.2mls of 1:1000 IV
- 3- Epinephrine 0.5mg IV
- 4- Epinephrine 0.5mg i.m.
- 5- Hydrocortisone 100mg i.v.

Answer & Comments

Answer: 4- Epinephrine 0.5mg i.m.

Immediate treatment of anaphylaxis includes cessation of whatever caused it. Oxygen, fluids and adrenaline/epinephrine 0.5mg i.m or subcutaneously. (checking concentrations of adrenaline is very important especially in high pressure situations). Intravenous adrenaline is potentially hazardous unless diluted appropriately.

[Q: 428] OnExamination -
Emergency medicine

A 76-year-old with a recent history of cerebral haemorrhage is admitted with a cough, worsening breathlessness and right pleuritic chest pain. He is also mildly pyrexial. His ventilation-perfusion scan reveals several areas of ventilation/perfusion mismatches in the right lower zone.

What is the most appropriate line of management?

- 1- aspirin therapy
- 2- antibiotics
- 3- inferior vena cava filter
- 4- low molecular weight heparin treatment
- 5- warfarin treatment

Answer & Comments

Answer: 3- inferior vena cava filter

This patient has PE following a recent haemorrhagic stroke. The risk of rebleeding into the stroke area is too high with anticoagulation. The best action would be percutaneous insertion of IVC filter which may be as effective as anticoagulation. It is used in cases where anticoagulation is a contraindication or in those in whom anticoagulation alone fails.

[Q: 429] OnExamination -
Emergency medicine

A 17-year-old girl presents following an overdose of Paracetamol, her parents having found her with empty packets of paracetamol. She states that she has taken 100 tablets, three hours earlier.

Which is the most appropriate step in this patient's management?

- 1- administer oral activated Charcoal 50g
- 2- give N-Acetylcysteine intravenously
- 3- Measure plasma Paracetamol concentration
- 4- Transfer to young person's psychiatric unit immediately
- 5- take no immediate action

Answer & Comments

Answer: 2- give N-Acetylcysteine intravenously

This patient has taken a huge paracetamol overdose only three hours previously so the paracetamol level would be pointless until after 4hrs. Also we know that she has taken a huge dose and that she needs urgent treatment. As absorption of paracetamol can be prevented by activated charcoal if given within 2 hours of ingestion it may be too late to use in this case. But generally algorithms suggest using NAC as early as possible. However, you would usually give activated charcoal as well particularly if taken with alcohol which may delay absorption.

[Q: 430] OnExamination -
Emergency medicine

A 38-year-old man experiences sudden deterioration after being admitted to the Intensive Care Unit because of severe pneumococcal pneumonia and septic shock. Arterial blood gas analysis reveals pH of 7.2, pO_2 of 90mmHg, pCO_2 of 35mmHg and HCO_3^- of 16mEq/L.

Which one of the following changes will be found in this patient?

- 1- Hyperventilation leading to the increase in CO₂ concentration
- 2- Increase production of HCO₃⁻
- 3- Increased renal excretion of HCO₃⁻
- 4- Raised hydrogen ions level in the blood
- 5- Respiratory acidosis

Answer & Comments

Answer: 4- Raised hydrogen ions level in the blood

This patient has metabolic acidosis with low HCO₃⁻ level while PaCO₂ level is normal.

The answer to this question is so simple for the scenario that in a patient with low pH, increased hydrogen ion concentration will be found.

[Q: 431] OnExamination -
Emergency medicine

A 18-year-old female is brought to A+E unconscious after having taken an overdose. On examination she has a Glasgow coma score of 6, a respiratory rate of 8 breaths per minute, a heart rate of 52 beats per minute and her blood pressure was 84/62 mmHg. Her pupils are small but are reactive to light, muscle tone is reduced and plantar responses are flexor.

Which of the following is she most likely to have taken in overdose?

- 1- Diazepam
- 2- Dihydrocodeine
- 3- Diphenhydramine
- 4- Ecstasy (MDMA)
- 5- Methanol

Answer & Comments

Answer: 2- Dihydrocodeine

Dihydrocodeine is an opiate analgesic and when taken in overdose has a number of toxic effects. It acts as a respiratory depressant leading to reduced respiratory rate. It can cause bradycardia and hypotension in large doses, papillary constriction is a diagnostic feature in opiate overdose it is also a CNS depressant and therefore causes coma in overdose. Benzodiazepines and antihistamines tend not to have the same cardiorespiratory effects as opiates, MDMA is a stimulant and can cause delirium, convulsions and ventricular arrhythmias. Diazepam would be less likely here due to the bradycardia and the hypotension.

[Q: 432] OnExamination -
Emergency medicine

A 50-year-old male who is well known to the casualty department attends inebriated. He has an alcoholic encephalopathy with a Glasgow Coma Scale of 13. He is jaundiced, describes no symptoms, but is mildly short of breath.

You are presented with his blood results:

Haemoglobin 7.4 g/dl (12 - 16 g/dl)
 White cell count 10.1 x 10⁹/L (4 - 10 x 10⁹/L)
 Platelets 137 x 10⁹/L (140-400 x 10⁹/L)
 Sodium 133 mmol/l (133 - 144 mmol/L)
 Potassium 3.7 mmol/l (3.5 - 5 x 10⁹/L)
 Urea 12 mmol/l (3 - 8 x 10⁹/L)
 Creatinine 113 micromol/l (50–100 µmol/L)
 AST 124 (5 - 40)
 Alkaline Phosphatase 224 (50 - 110)
 Total Protein 54 g/l (60 - 80g/L)
 Bilirubin 63 micromol/l (3- 18 µmol/L)
 Cholesterol 15.3 mmol/l (<5.5 mmol/L)
 Triglycerides 7.2 mmol/l (<2.2mmol/L)
 Blood film Profound spherocytosis

Which of the following is the most appropriate treatment for this patient?

- 1- IV Steroids
- 2- Oesophago-gastro-duodenoscopy
- 3- MRI pancreas
- 4- Supportive therapy
- 5- Urgent laparotomy

Answer & Comments

Answer: 4- Supportive therapy

A combination of jaundice, alcoholic hepatitis, hyperlipidaemia, and haemolysis is known as Zieve's syndrome. There is no specific treatment for Zieve's syndrome, but supportive therapy is indicated- correction of clotting abnormalities, treatment of haemolysis, treating alcohol withdrawal, preventing further alcohol intake and adequate nutrition. The spherocytosis is the result of the haemolysis. Pancreatitis is a possible differential diagnosis here, but in the first instance one would request an amylase rather than an MRI of the pancreas.

[Q: 433] OnExamination -
Emergency medicine

A 62-year-old male attends A+E with a severe nose bleed. He is known to have alcoholic cirrhosis. His investigations reveal:

haemoglobin 10.9 g/dL (13.0-18.0)
white cell count $5 \times 10^9/L$ (4-11)
platelet count $60 \times 10^9/L$ (150-400)
prothrombin time 17.5s (11.5-15.5)
APPT 42s (30-40)
fibrinogen 0.7 g/L (1.8-5.4)

What is the most appropriate blood product for this patient?

- 1- Cryoprecipitate
- 2- Factor VIII
- 3- Platelets
- 4- Prothrombin complex concentrate
- 5- whole blood

Answer & Comments

Answer: 1- Cryoprecipitate

The most significant abnormality is the low Fibrinogen. Therefore the best product to correct the fibrinogen out of those given is cryoprecipitate.

To correct a coagulopathy you need to aim for Fibrinogen $> 1.0g/L$, Platelets $>50 \times 10^9/L$, PT and APTT < 1.5 upper range of normal- so from the results you can see the most significant abnormality is the low fibrinogen, the platelets are low and APTT/PT prolonged but not really sufficient to cause bleeding.

[Q: 434] OnExamination -
Emergency medicine

A 70-year-old female is admitted 12 hours after taking an overdose of aspirin.

Investigations revealed:

Serum sodium 138 mmol/L (137-144)
Serum potassium 5.9 mmol/L (3.5-4.9)
Serum bicarbonate 14 mmol/L (20-28)
Serum urea 18.1 mmol/L (2.5-7.5)
Serum creatinine 238 $\mu\text{mol/L}$ (60-110)
Serum salicylate 1120 mg/L (8 mmol/L)

What is the most appropriate treatment of this patient?

- 1- Haemodialysis
- 2- Haemofiltration
- 3- Intravenous sodium bicarbonate.
- 4- Peritoneal dialysis.
- 5- Urine alkalinization.

Answer & Comments

Answer: 1- Haemodialysis

This patient is at major risk of aspirin toxicity as reflected by the excessive aspirin concentration and appears to have developed acute renal failure ?s acidotic with an elevated

potassium. Bicarbonate is recommended as a supportive therapy but in this patient, Haemodialysis is the treatment of choice. The latter is advised when the plasma-salicylate concentration is greater than 700 mg/litre (5.1 mmol/litre) or in the presence of severe metabolic acidosis as recommended within the BNF poisons section.

There is nothing wrong with haemofiltration it just removes the toxin more slowly.

[Q: 435] OnExamination -
Emergency medicine

A precordial thump:

- 1- Can be given following an unwitnessed cardiac arrest
- 2- Should be administered after a warning has been given to the patient
- 3- Can be delivered up to twice during a cardiac arrest
- 4- Delivers approximately 10 Joules of energy
- 5- Should be aimed at the position of V4 on the anterior chest wall

Answer & Comments

Answer: 4- Delivers approximately 10 Joules of energy

The precise indication for performing a precordial thump is following a witnessed or monitored cardiac arrest. Warning a patient who has arrested will serve little purpose! Only one thump should be delivered (before the first 200J defibrillatory shock) over the lower third of the sternum. Approximately 7 to 10 Joules of energy is delivered with an appropriately weighted thump (potential energy to mechanical energy to electrical energy).

[Q: 436] OnExamination -
Emergency medicine

A 51-year-old lady presented to hospital with

a two-day history of malaise and headache. On the day of admission the headache had become more intense and was associated with pain in her neck. Her husband reported that she had also been febrile and confused at times. She had previously been well and had no significant past medical history.

On examination, she was febrile 38.1°C, looked unwell and was photophobic. Kernig's and Brudzinski's signs were positive. The fundi were normal with no evidence of papilloedema.

Following a normal CT scan a lumbar puncture was performed and CSF analysis showed:

White cells	200/mm ³
Red cells	2/mm ³
CSF protein	0.9 g/L
CSF glucose	1.6 mmol/L
Plasma glucose	5.3 mmol/L

What is the most likely causative organism?

- 1- Escherichia coli
- 2- Listeria monocytogenes
- 3- Mycobacterium tuberculosis
- 4- Streptococcus pneumoniae
- 5- Streptococcus pyogenes

Answer & Comments

Answer: 4- Streptococcus pneumoniae

The most common causes of bacterial meningitis in persons over 50 years of age are:

1. Streptococcus pneumoniae
2. Neisseria meningitidis
3. Listeria monocytogenes
4. "Gram-negative bacilli"

Although this question tries to establish whether candidates are aware of the most common cause of meningitis in this group, some questions in the exam give additional clues as to the cause of meningitis.

Physical examination may provide clues to the aetiology of meningitis in affected patients:

(i) Morbilliform rash with pharyngitis and lymphadenopathy may suggest a viral etiology (EBV, CMV, adenovirus, HIV).

(ii) Macules and petechiae that rapidly evolve into purpura suggest meningococemia (with or without meningitis).

(iii) Vesicular lesions in a dermatomal distribution suggest varicella zoster virus.

(iv) Genital vesicles suggest HSV-2 meningitis.

(v) Sinusitis or otitis suggests direct extension into the meninges, usually with *Streptococcus pneumoniae* and *Haemophilus influenzae*.

(vi) Rhinorrhea or otorrhea suggest a CSF leak from a basilar skull fracture, with meningitis most commonly caused by *Streptococcus pneumoniae*.

(vii) Hepatosplenomegaly and lymphadenopathy suggest a systemic disease, including viral (eg, mononucleosis-like syndrome in EBV, CMV, and HIV) and fungal (eg, disseminated histoplasmosis) disease.

(viii) The presence of a murmur suggests infective endocarditis with secondary bacterial seeding of the meninges.

(ix) Evidence of parotitis is observed in some cases of mumps meningitis.

Kernig's sign In a supine patient, flex the hip to 90° while the knee is flexed at 90°. An attempt to further extend the knee produces pain in the hamstrings and resistance to further extension.

Brudzinksi sign: Passively flex the neck while the patient is in a supine position with extremities extended. This maneuver produces flexion of the hips in patients with meningeal irritation.

[Q: 437] OnExamination -
Emergency medicine

A youth worker, aged 40, presents to Accident and Emergency with vomiting. On detailed questioning, he states that he has taken about 36 paracetamol tablets 2 hours previously. He is vomiting profusely with a BP of 90/60 mmHg.

Which of the following measures would be the most appropriate immediate step in the management of this patient?

- 1- Paracetamol levels
- 2- Oral methionine
- 3- IV N-acetyl cysteine
- 4- IV fluids
- 5- Coagulation screen

Answer & Comments

Answer: 4- IV fluids

The most pressing issue in this patient is resuscitation as he is vomiting and is hypotensive. It is too early to carry out paracetamol levels as these should be carried out at 4 hours. Although he states that he has taken 18g of paracetamol this may NOT be the case and he may not require NAC. You can wait. An elevated INR gives an indication of hepatocellular damage and again this will not be seen at presentation of paracetamol overdose.

[Q: 438] OnExamination -
Emergency medicine

A 16-year-old girl presents with bilateral cervical lymphadenopathy. Her lymph node biopsy reveals a nodular sclerosing Hodgkin's disease.

Which one of the following features indicates a poorer prognosis?

- 1- Fatigue
- 2- Mediastinal mass of 3cm

- 3- Night sweats
- 4- Pruritis
- 5- Recent Epstein-Barr virus infection

Answer & Comments

Answer: 3- Night sweats

Important prognostic features in HD are Stage

- B symptoms- Fever/ night sweats and weight loss

- Mass > 10 cm

Therefore although fatigue and pruritus common, have no prognostic significance.

EBV infection commonly associated with HD but has no prognostic significance.

[Q: 439] OnExamination -
Emergency medicine

A 16-year-old girl presented with fever, headache and photophobia. Investigations revealed:

Cerebrospinal fluid examination

Opening pressure 260 mm H₂O (50-180)

Total protein 0.8 g/L (0.15-0.45)

Glucose 4.2 mmol/L (3.3-4.4)

White cell count 60 per ml (<5)

Lymphocytes 90% (60-70)

" Plasma glucose 6.4 mmol/L (3.0-6.0)

What is the most likely diagnosis?

- 1- Bacterial meningitis
- 2- Cryptococcal meningitis
- 3- Tuberculosis meningitis
- 4- Viral encephalitis
- 5- Viral meningitis

Answer & Comments

Answer: 5- Viral meningitis

A normal Cerebrospinal fluid (CSF) glucose together with a CSF lymphocytosis, an increased opening pressure, and a raised CSF protein is typical of a viral meningitis, which would be high on the list of differentials in patients of this age group (together with bacterial meningitis).

A handy guide to CSF findings

[Q: 440] OnExamination -
Emergency medicine

A 70 year-old male is admitted with haematemesis. He is currently being treated with warfarin for atrial fibrillation and his INR returns as 10.

Which of the following is the most appropriate immediate treatment of his INR?

- 1- cryoprecipitate
- 2- fresh frozen plasma
- 3- intravenous vitamin K
- 4- oral vitamin K
- 5- recombinant Factor VIII concentrate

Answer & Comments

Answer: 2- fresh frozen plasma

This patient has had a bleed related to a grossly elevated INR. Consequently the INR needs correction as rapidly as is possible. Vitamin K will correct the INR over a few days whereas, fresh frozen plasma will correct the bleeding time rapidly.

[Q: 441] OnExamination -
Emergency medicine

An 81 year-old female is admitted following a seizure although her relatives state that prior to this she had been increasingly confused, unsteady and unable to look after herself over the last 2-3 weeks.

On examination she was drowsy and had a temperature of 37.5°, and a blood pressure of

192/108 mmHg. She had a mixed aphasia, with a mild right hemiparesis.

What is the most likely diagnosis?

- 1- Acute cerebral infarction
- 2- Acute intracerebral hemorrhage
- 3- Cerebral abscess
- 4- Chronic subdural haematoma
- 5- Glioblastoma

Answer & Comments

Answer: 4- Chronic subdural haematoma

The history of variable "confusion" and unsteadiness for some weeks followed by an acute exacerbation is a typical presentation of a subdural haematoma in the elderly population.

Cerebral abscess is unlikely due to the absence of significant fever. Acute infarction or acute intracerebral hemorrhage would not explain the two weeks history of confusion and unsteadiness. Astrocytoma usually causes symptoms over months to years.

Mixed aphasia (or transcortical mixed aphasia) is, simply, not a complete 'global aphasia'. In global aphasia there is receptive and expressive dysphasia. Further reading on dysphasias Patients can often repeat words but not understand commands, name objects or have intelligible spontaneous speech. 'Mixed aphasia' is not specific for stroke, although it can be caused by it. It may be caused by Alzheimer's disease, bilateral cerebral damage, tumours, thalamic lesions and so on. It is an excellent choice of language defect for a Best of Five question since it is a good distractor.

[Q: 442] OnExamination -
Emergency medicine

Which of the following is currently recommended as the drug of choice in treating refractory ventricular fibrillation or pulseless

ventricular tachycardia?

- 1- Adenosine
- 2- Amiodarone
- 3- Bretyllium
- 4- Lidocaine
- 5- Magnesium

Answer & Comments

Answer: 2- Amiodarone

300mg of amiodarone made up to 20ml with 5% dextrose given as an intravenous bolus is the drug of choice. 100mg of lidocaine may be given intravenously when amiodarone is unavailable. Historically 5mg / Kg of Bretyllium was given, but it is no longer recommended.

[Q: 443] OnExamination -
Emergency medicine

A 22-year-old female develops a wheeze and extensive rash whilst eating a Chinese take-away. On examination, she has extensive wheeze and stridor, with urticaria covering her upper and lower limbs and trunk. Her BP is 80/45 mmHg.

What is the likely diagnosis?

- 1- C1 Esterase Deficiency
- 2- Food poisoning
- 3- Idiopathic urticaria
- 4- Monosodium glutamate syndrome
- 5- Peanut allergy

Answer & Comments

Answer: 5- Peanut allergy

Chinese cooking uses cashew nuts in many dishes, and patients with peanut allergy may also experience an anaphylactic reaction with cashew nuts. Chinese chefs also use peanut oil in the stir fry, and this may also precipitate an allergic reaction. An acute hypersensitivity reaction to monosodium glutamate (MSG) a

preservative common in Chinese food, may give rise to the "MSG syndrome". This is characterized by a sudden onset of headache, heartburn, palpitations, sweating, swelling, and flushing of the face. Patients may report a sense of increased facial pressure or tingling in the face. Symptoms generally start within 2 hours of eating foods rich in MSG. This condition is generally self-limited and will resolve. Antihistamines can be helpful in some cases. It is extremely unlikely that this syndrome will cause shock- which is what this patient presents with given the hypotension.

[Q: 444] OnExamination -
Emergency medicine

A 65 year-old male presents with acute severe headache, ataxia and vomiting. Six hours later he became drowsy. On examination he had left horizontal nystagmus, a partial left sixth cranial nerve palsy and extensor plantar responses. His blood pressure was 188/110 mmHg.

What is the most likely cause for this deterioration?

- 1- brain stem herniation
- 2- cerebral oedema
- 3- dehydration
- 4- malignant hypertension
- 5- non-convulsive status epilepticus

Answer & Comments

Answer: 1- brain stem herniation

The most likely explanation of the sudden deterioration will be brain stem herniation. The acute onset of symptoms with headache and vomiting indicating an acute intracranial haemorrhage. Mass effect created the brain stem herniation. Intravenous mannitol, intubation/ventilation, urgent CT brain and neurosurgical referral are indicated.

[Q: 445] OnExamination -
Emergency medicine

A 60-year-old man presents with an episode of memory loss. Three days earlier he had become confused. His wife led him into the house - he apparently sat down at her request, and had a cup of tea. He then wandered around the house, confused, but remained conscious and able to have some conversation with his wife, though continuing to ask similar questions repeatedly. After three hours, he abruptly returned to normal and had no recollection of the events.

What is the most likely diagnosis?

- 1- alcohol related amnesia
- 2- chronic subdural haematoma
- 3- complex partial status epilepticus
- 4- hysterical fugue state
- 5- transient global amnesia

Answer & Comments

Answer: 5- transient global amnesia

This is the typical clinical description of transient global amnesia which represent a transient vascular insufficiency of both hippocampi.

[Q: 446] OnExamination -
Emergency medicine

A 60-year-old male is brought to casualty in the early hours of the morning after being found unconscious in the street. On examination, he was drowsy but localised to painful stimuli. There was no evidence of head injury or meningism. Investigations revealed:

sodium 134 mmol/L (137-144)
potassium 4.0 mmol/L (3.5-4.9)
urea 4.0 mmol/L (2.5-7.5)
creatinine 80 micromol/L (60-110)
glucose 4.5 mmol/L (3.0-6.0)
chloride 100 mmol/L (95 - 107)

bicarbonate 25 mmol/L (20 - 28)

plasma osmolality 385 mosmol/Kg (278 - 305)

What is the most likely explanation for his presentation?

- 1- diazepam poisoning
- 2- ethanol poisoning
- 3- methanol poisoning
- 4- phenobarbitone poisoning
- 5- Phenytoin poisoning

Answer & Comments

Answer: 2- ethanol poisoning

This gent is intoxicated. He has a normal acid base balance slight hyponatraemia reflecting dilution and very high osmolality reflecting the presence of ethanol. Methanol would produce an acidosis. Diazepam is not an osmolyte nor would the other agents produce this picture.

[Q: 447] OnExamination -
Emergency medicine

A 40-year-old farmer presented to Casualty with a 24-hour history of fever and increasing confusion. On examination he was febrile 39.5°. A generalized erythematous rash, covering most of his body, was observed. He also had a paronychia infection of his right index finger, with lymphangitis extending caudally and with axillary lymphadenopathy. His heart rate was measured at 120 beats per minute with a blood pressure of 80/60 mmHg.

What is the most likely diagnosis?

- 1- Hantavirus infection
- 2- Leptospirosis
- 3- Orf
- 4- Staphylococcal toxic shock syndrome
- 5- Stevens-Johnson syndrome

Answer & Comments

Answer: 4- Staphylococcal toxic shock syndrome

The history is typical of staphylococcal toxic shock syndrome (TSS) ?shock, fever, confusion and rash. The primary source of infection in this case is the paronychia of his right index finger. Hantavirus infections (viral zoonoses transmitted via rodents) typically have two distinct presentations: either as a haemorrhagic fever with renal failure or as an acute pulmonary syndrome. The former manifestation is commonest in the far east and eastern Europe, while the latter is the predominant form in the southwestern United States and South America. Leptospirosis does not typically cause a rash and is often associated with jaundice; leptospirosis would not explain the lesion on his finger. Orf, a zoonotic infection caused by a pox virus, presents with painless ulcerated lesions on the hands of farmers, but does not fully explain this clinical picture. Stevens-Johnson syndrome typically starts with an erythema multiforme-type rash that spreads widely and involves the buccal mucosa and conjunctivae; often caused by antibiotic therapy, but does not fit the clinical picture presented here.

[Q: 448] OnExamination -
Emergency medicine

A 35-year-old lady presented with left sided weakness. She has a young family with a 5-year-old son and a 2-year-old daughter. Previously she had two spontaneous abortions. After the birth of her last child she developed a Deep Vein Thrombosis and received three months of anticoagulation with warfarin.

On examination she has left sided weakness with pyramidal signs. A CT head scan showed a right middle cerebral artery territory infarct.

Which of the following is the most likely diagnosis?

- 1- Hypertension
- 2- Kawasaki syndrome
- 3- Patent foramen ovale
- 4- Systemic lupus erythematosus
- 5- Thrombotic thrombocytopenic purpura

Answer & Comments

Answer: 4- Systemic lupus erythematosus

This patient has a prothrombotic tendency suggestive of the lupus anticoagulant with recurrent abortions, previous DVT and now she has developed a left hemiparesis.

[Q: 449] OnExamination -
Emergency medicine

A 16-year-old man is brought to the Accident and Emergency department with a GCS (Glasgow Coma Scale) rating of 3/15. Within 10 minutes he regained consciousness with a GCS of 15/15, is sitting up and talking.

What is he likely to have taken?

- 1- Inhaled solvent glue
- 2- Smoked heroine
- 3- Smoked marijuana
- 4- Snorted cocaine
- 5- Taken ecstasy

Answer & Comments

Answer: 1- Inhaled solvent glue

This patient was markedly comatose on arrival but quickly regains consciousness. This suggests a short acting (probably) inhaled anaesthetic like agent ?Glue. Marijuana would not be expected to produce this level of coma and the effects of cocaine would last much longer. The inhaled solvents, due to their lipophilicity, are rapidly absorbed through the lungs and then quickly distributed to the brain and other organs. The effects therefore appear within minutes of inhalation. Typical

substances that are inhaled include 'Toluene aromatic hydrocarbons' and Butane.

[Q: 450] OnExamination -
Emergency medicine

A 26-year-old woman presented in acute shock at 35 weeks of pregnancy with profuse vaginal bleeding. She had suffered two previous miscarriages. She had a pulse of 110 beats per minute, blood pressure of 110/84 mmHg and no foetal heart sounds were audible.

Investigations revealed:

Haemoglobin 9.5 g/dL

Platelets $66 \times 10^9/L$

Prothrombin time 21 sec (Control 11.5 - 15.5)

APTT 52 sec (Control 30 - 40)

Fibrinogen 0.5 g/L (NR 2 - 4)

What is the most appropriate next step in management?

- 1- antithrombin III infusion
- 2- fibrinogen replacement infusion (cryoprecipitate)
- 3- intravenous heparin
- 4- platelet transfusion
- 5- transfusion of two units group O Rhesus D negative blood

Answer & Comments

Answer: 2- fibrinogen replacement infusion (cryoprecipitate)

The clinical picture is disseminated intravascular coagulation. When bleeding is the major problem, the aim is to maintain the prothrombin and activated thromboplastin time at a ratio of 1.5 times of the control and the fibrinogen level above 1g/L. Platelet transfusion is recommended if the count is less than $50 \times 10^9 /L$. Anaemia is not very severe so in this case fibrinogen replacement

would be the appropriate choice. (Ref: Oxford textbook of Medicine)

[Q: 451] OnExamination -
Emergency medicine

A 70-year-old man was admitted with pallor, light-headedness and loss of energy. On the day prior to admission he had reported loose dark stools. Examination revealed a pulse of 110 per minute and a blood pressure of 106/70 mmHg.

Investigations revealed:

Haemoglobin 7.2 g/dL (14-18)

MCV 72 fL (78-96)

White cell count $11.3 \times 10^9/L$ (4-11)

Platelet count $480 \times 10^9/L$ (150-400)

What is the most appropriate next step in his management?

- 1- Barium meal
- 2- Blood transfusion
- 3- Endoscopy
- 4- Parenteral iron infusion
- 5- Proton pump inhibitor therapy

Answer & Comments

Answer: 2- Blood transfusion

There is only one answer here and that is blood transfusion. He has clearly had a major GI bleed since he presents with symptoms of shock with a high resting heart rate and lowish blood pressure the day after what sounds like melaena. What is more he has a significant microcytic anaemia. He should be resuscitated with blood transfusion and then send for upper GI endoscopy. A barium meal will not help a bleeding vessel. Parenteral iron is for chronic anaemia not acute bleeds and proton pump inhibitors, although widely used, have no supportive evidence and are nowhere near as important as giving blood to this man.

[Q: 452] OnExamination -
Emergency medicine

A 70-year-old man underwent emergency surgery for an acute abdomen. Following surgery he was noted to have become oliguric. Investigations revealed the following:

sodium 121 mmol/L (137-144)

potassium 6.6 mmol/L (3.5-4.9)

chloride 92 mmol/L (95-107)

Urea 17.2 mmol/l (3-8)

Creatinine 250 micromol/L (60-110)

Arterial blood gas pH 7.16

Standard Bicarbonate 15.6 (21-27)

What is the calculated anion gap for this patient?

- 1- 5 mmol/L
- 2- 10 mmol/L
- 3- 15 mmol/L
- 4- 20 mmol/L
- 5- 25 mmol/L

Answer & Comments

Answer: 4- 20 mmol/L

Anion gap is calculated as $(Na+K) - (Cl+HCO_3)$. Therefore in this patient, the calculated value is 20 mmol/l. The normal anion gap is between 8-16 mmol/l, the excessive value reflecting the presence of other acidic anions and in this case with the metabolic acidosis the constituents may be lactate etc.

[Q: 453] OnExamination -
Emergency medicine

These are the blood gas results obtained in a 20-year-old female admitted to hospital.

hydrogen ion concentration 35 nmol/L (35-45)

pH 7.45 (7.35-7.45)

pCO₂ 6.8 kPa (4.6-5.9)

bicarbonate 32 mmol/L (22 - 26)

Which one of the following is a recognised cause of this acid-base disorder?

- 1- Amitriptyline overdose
- 2- Cushing's syndrome
- 3- hepatic failure
- 4- pregnancy
- 5- salicylate poisoning

Answer & Comments

Answer: 4- pregnancy

This patient has a mild metabolic alkalosis with what appears to be respiratory compensation as reflected by the elevated pCO₂. Amitriptyline overdose is associated with acidosis as is salicylate poisoning. Hepatic failure usually presents with acidosis. This type of picture is associated with prolonged vomiting (as in pregnancy), diarrhoea, diuretic therapy and in Cushing's syndrome or in those receiving high dose corticosteroids. With no other information provided for this case, common things being common, one should select pregnancy as the best answer for a 20-year-old female.

[Q: 454] OnExamination -
Emergency medicine

A 32-year-old female smoker presents with acute severe asthma. The SaO₂ are 80% on 15L of Oxygen and the pO₂ is 8.2kPa (10.5-13). There is widespread expiratory wheeze throughout the chest. She is given IV Hydrocortisone, 100% oxygen and 5mg of nebulised salbutamol.

What is the next best option?

- 1- Oral prednisolone
- 2- IV Augmentin
- 3- IV Magnesium
- 4- IV Potassium
- 5- IV Theophylline

Answer & Comments

Answer: 3- IV Magnesium

This question focuses on acute treatment of asthma. Your initial approach should be SOS salbutamol, oxygen and steroids (IV). In the meantime a CXR should be organised to rule out pneumothorax. You should then consider further efforts to treat bronchoconstriction- a silent chest, or a tiring patient should suggest ITU review

The recommended dose of Magnesium is 2g over 30 minutes. The mechanism by which it has its effect is not fully understood, but it is thought that low Magnesium levels in bronchial smooth muscle favour bronchoconstriction. IV theophylline may be considered, but Magnesium would be higher on the list. IV antibiotic may be indicated, but your initial focus should be promoting bronchodilation. IV Potassium may be required as the beta agonists push down the potassium. Oral Prednisolone can wait, as you have already given IV hydrocortisone as part of your SOS approach.

[Q: 455] OnExamination -
Emergency medicine

An anxious 22-year-old female with a high respiration rate has the following arterial blood gas results:

pH	7.27 (7.35-7.45)
pCO ₂	2.6 KPa (3.5-5.5)
Base excess	-12 mmol/l

What is the interpretation of the acid-base status?

- 1- Combined metabolic and respiratory acidosis
- 2- Combined metabolic and respiratory alkalosis
- 3- Metabolic acidosis with some compensatory respiratory alkalosis

- 4- Respiratory acidosis with some compensatory metabolic alkalosis
- 5- Respiratory alkalosis with some compensatory metabolic acidosis

Answer & Comments

Answer: 3- Metabolic acidosis with some compensatory respiratory alkalosis

This patient has a metabolic acidosis as evidence by a pH of 7.27 and a negative base excess, which is a marker of the extent of acidosis. The low CO₂ is a reflection of the physiological respiratory compensation which is attempting to normalize pH by clearing the acidic gas CO₂.

[Q: 456] OnExamination -
Emergency medicine

A 20-year-old man presented after ingesting a drug at a party. Investigations revealed:

serum creatine kinase 10,000 IU/L (24-195)

Which one of the following drugs is most likely to have been responsible?

- 1- "Ecstasy" (MDMA)
- 2- Cannabis
- 3- Diazepam
- 4- Gamma hydroxybutyrate (GHB)
- 5- Ketamine

Answer & Comments

Answer: 1- "Ecstasy" (MDMA)

Symptoms of an acute MDMA toxic reaction include agitation, tachycardia, hypertension, dilated pupils, trismus, and sweating, whereas the more severe cases may be characterized by hyperthermia, disseminated intravascular coagulation (DIC), rhabdomyolysis, and acute renal failure. In more severe cases, elevated creatine kinase levels are often present, with levels as high as 555,000 IU/L being reported. Neither GHB nor Ketamine are associated with

elevated CK levels. PCP (Phencyclidine) is another drug which may cause an elevated CK in overdose.

[Q: 457] OnExamination -
Emergency medicine

A 17-year-old girl underwent emergency splenectomy after a domestic accident.

Which one of the following organisms is most likely to cause life-threatening infection in the future?

- 1- Actinomyces
- 2- Haemophilus influenzae
- 3- Pseudomonas aeruginosa
- 4- Staphylococcus aureus
- 5- Streptococcus pneumoniae

Answer & Comments

Answer: 5- Streptococcus pneumoniae

Following splenectomy a person is at risk of Streptococcus pneumoniae, Haemophilus influenzae, Neisseria meningitidis, Escherichia coli and Pseudomonas aeruginosa.

By far the most common is Streptococcus pneumoniae- which can cause life threatening infection.

[Q: 458] OnExamination -
Emergency medicine

A 44-year-old male with Child's grade C cirrhosis presented with haematemesis.

Which one of the following drugs, administered intravenously, would be the most appropriate, immediate, treatment?

- 1- Isosorbide dinitrate.
- 2- Omeprazole.
- 3- Propranolol
- 4- Somatostatin
- 5- Tranexamic acid.

Answer & Comments

Answer: 4- Somatostatin

The suggestion is that this patient is at particularly high risk of oesophageal varices. Child's classification of cirrhosis is a points scale based upon ascites/bilirubin etc reflecting prognosis. Graded depending upon the points scored from A-C with C reflecting greatest risk. Somatostatin acts to reduce portal pressures and has been demonstrated to be as effective as endoscopy at controlling variceal bleeding in the acute setting. B-blockers can be used as oral prophylaxis for oesophageal varices. IV Omeprazole has also been shown to be effective in reducing mortality in GI haemorrhage of any cause (NEJM 2002) but somatostatin may be expected to be superior for the above patient.

[Q: 459] OnExamination -
Emergency medicine

Which of the following would be expected features of a LEFT Posterior cerebral artery occlusion :

- 1- a right homonymous hemianopia
- 2- internuclear ophthalmoplegia
- 3- Wernicke's aphasia
- 4- pure aphasia (i.e. without alexia)
- 5- decerebrate state

Answer & Comments

Answer: 1- a right homonymous hemianopia

b- typical of multiple sclerosis. c+d-Middle cerebral artery. e-False? Pontine lesion. Other possible findings in posterior left cerebral artery occlusion: cortical blindness, visual hallucinations, thalamic syndrome, Claude's and Weber's syndromes.

[Q: 460] OnExamination -
Emergency medicine

A 19-year old girl has been brought to A & E

by her friends following a night out at a party. Her friends comment that she has been talking by herself about 'irrelevant things'. She seems agitated and restless. On examination, her reflexes are increased and an ECG demonstrates ventricular ectopics.

What kind of substance abuse do you suspect at this point?

- 1- Alcohol
- 2- Barbituate
- 3- Cannabis
- 4- Ecstasy
- 5- Glue sniffing

Answer & Comments

Answer: 4- Ecstasy

This is a case of Ecstasy overdose. Ecstasy (3,4-methylenedioxymethamphetamine, MDMA) stimulate the central nervous system. It causes increased alertness and self-confidence, euphoria, extrovert behaviour, increased talkativeness with rapid speech, lack of desire to eat or sleep, tremor, dilated pupils, tachycardia, and hypertension. More severe intoxication is associated with excitability, agitation, paranoid delusions, hallucinations with violent behaviour, hypertonia, and hyperreflexia. Convulsions, rhabdomyolysis, hyperthermia, and cardiac arrhythmias may also develop. In severe cases of MDMA poisoning, hyperthermia, disseminated intravascular coagulation, rhabdomyolysis, acute renal failure, and hyponatraemia are observed. Hepatic damage has also been reported. Rarely, poisoning due to amphetamines may result in intracerebral and subarachnoid haemorrhage and acute cardiomyopathy; these complications may be fatal. Hyperthyroxinaemia may be found in chronic amphetamine users.

[Q: 461] OnExamination -
Emergency medicine

A 35-year-old woman with a five year history of treated hypothyroidism, presented following an episode of vomiting and collapse. There was a short history of weight loss. On examination she had a temperature of 37.7C, a blood pressure of 80/40 mmHg and vitiligo.

Which one of the following, given intravenously, would be the most appropriate initial management?

- 1- 10% dextrose infusion
- 2- Cefotaxime
- 3- Fludrocortisone
- 4- Hydrocortisone
- 5- tri-iodothyronine

Answer & Comments

Answer: 4- Hydrocortisone

This patient is likely to have Addison's disease based upon her history, autoimmune disease, and presentation. She requires treatment with IV hydrocortisone which can be a life saving manoeuvre in acute hypoadrenalism.

[Q: 462] OnExamination -
Emergency medicine

A 22-year-old man suffers a deep laceration to the forearm resulting in transection of the median nerve.

Following this injury, the nerve will undergo which of the following pathological processes?

- 1- Chronic inflammation
- 2- Coagulative necrosis
- 3- Fibrinoid necrosis
- 4- Segmental demyelination
- 5- Wallerian degeneration

Answer & Comments

Answer: 5- Wallerian degeneration

Degeneration of the portion of the nerve distal to the injury. Segmental demyelination is a feature seen in axons in the central nervous system with multiple sclerosis.

[Q: 463] OnExamination -
Emergency medicine

A 51-year-old policewoman presents with a long history of watering of her left eye. Over the preceding 3 days she had developed facial pain and swelling. On examination she is well, afebrile, has a watering left eye, and a red, tense, tender swelling between the side of the nose and just below the left inner canthus.

What is the diagnosis?

- 1- Acute dacrocystitis
- 2- Orbital cellulitis
- 3- Sinusitis
- 4- Erysipelas
- 5- Epiphora

Answer & Comments

Answer: 1- Acute dacrocystitis

The long history of eye watering suggests long-standing obstruction of the nasolacrimal duct. This predisposes to acute infection of the lacrimal sac (acute dacrocystitis) which has the clinical features described above. Epiphora is another name for eye watering. The causes of eye watering are: Iritis, Corneal foreign body, Acute glaucoma, Obstruction to the lacrimal passageways (including VIIth nerve palsy) and Chronic eye inflammation.

[Q: 464] OnExamination -
Emergency medicine

A 19-year-old girl presents with an overdose of Paracetamol.

Which of the following statements is correct?

- 1- Acetylcystine should routinely be given if the presentation is within the first 12 hours of overdose.

- 2- Because she is over the age of 6, she is unlikely to develop significant toxicity.
- 3- Liver function tests should be monitored.
- 4- The mortality in those with an AST of >350 IU/L is 4%.
- 5- Hospitalisation will be needed for at least 5 days.

Answer & Comments

Answer: 3- Liver function tests should be monitored.

Treatment with N-acetyl cysteine (NAC) is given according to a standard nomogram. NAC may be useful up to 36 hours following ingestion. Children under the age of 6 are unlikely to develop significant toxicity, but adolescents have a higher incidence of toxic plasma levels following ingestion, and a higher incidence of abnormal AST >1000/U/L. Even after serious hepatotoxicity, the mortality rate is under 0.5%. The occasional patient may require liver transplantation.

[Q: 465] OnExamination -
Emergency medicine

A 21-year-old man, who has a past history of IV drug abuse, presents 12 hours after taking an overdose of 480 mg of codeine and 30 g of paracetamol. His blood pressure is 100/60 mmHg and he has pin-point pupils.

What is the most appropriate management for this patient?

- 1- 500ml 10% glucose IV over 4 hours
- 2- 1 litre normal saline IV over 6 hours
- 3- IV naloxone
- 4- IV flumazenil
- 5- start N-acetylcysteine

Answer & Comments

Answer: 5- start N-acetylcysteine

This patient presents 12 hours after taking a potentially fatally toxic dose of paracetamol. Under the circumstances provided in this question where there is an absence of data relating to pulse rate (as he is probably not in shock), respiratory rate (reflecting respiratory depression) or blood glucose, the most appropriate intervention at this 12 hour time point would be N-acetylcysteine.

The urgency of treatment is underlined by the fact that the incidence of hepatotoxicity is worse if treatment is delayed. Trials of N-acetylcysteine suggest that the incidence of hepatotoxicity is 1% in those treated within 8 hours v 46% in those treated after 16 hours.

[Q: 466] OnExamination -
Emergency medicine

A 42-year-old female is admitted following an overdose of Diazepam and alcohol. On examination she was unconscious with a core temperature of 34.5°C and a blood pressure of 110/80 mmHg.

Investigations reveal:

Creatinine 242 micromol/L (60-100)

AST 500 U/L (0-40)

Gamma GT 35 U/L (<50)

" urine microscopy no cells or organisms

" urine dipstick analysis blood+++

" Ultrasound abdomen normal

Which one of the following is the most likely cause of these findings?

- 1- Associated Paracetamol poisoning
- 2- Chronic renal failure
- 3- Dehydration
- 4- Hypothermia
- 5- Rhabdomyolysis

Answer & Comments

Answer: 5- Rhabdomyolysis

This patient has taken an overdose of diazepam and has collapsed for an indeterminate period. She is now seen with renal impairment. The features together with the elevated AST (from muscle) suggest a diagnosis of rhabdomyolysis.

[Q: 467] OnExamination -
Emergency medicine

A 55-year-old male presented six hours after taking an overdose of Lithium tablets which had been prescribed for a bipolar affective disorder.

On examination he was tremulous, had suffered a convulsion and had a Glasgow coma scale of 12/15. His serum lithium concentration was 5.0 mmol/L (0.5 - 1.0)

What is the most appropriate management of this patient?

- 1- Activated charcoal
- 2- Forced alkaline diuresis
- 3- Furosemide 100 mg intravenously twice daily
- 4- Haemodialysis
- 5- Measure lithium concentration in 2 hours

Answer & Comments

Answer: 4- Haemodialysis

The patient has a severe lithium overdose as reflected by markedly elevated Lithium concentrations and features of impaired consciousness, tremor and seizures. This needs urgent management. Activated charcoal does not bind Lithium effectively and is therefore ineffective except where co-ingestion of other poisons is suspected. Haemodialysis is the mainstay of treatment for acute Lithium toxicity.

[Q: 468] OnExamination -
Emergency medicine

A 24-year-old man presented twelve hours

after an overdose of dihydrocodeine 1.2 g and paracetamol 30 g. He had pinpoint pupils, a Glasgow Coma Scale score of 14 and a blood pressure of 100/60 mmHg.

Which one of the following is the most appropriate management?

- 1- 500ml of 10% glucose intravenously over four hours.
- 2- Intravenous Flumazenil.
- 3- Intravenous Naloxone.
- 4- Intravenous N-acetylcysteine.
- 5- Oral activated charcoal.

Answer & Comments

Answer: 4- Intravenous N-acetylcysteine.

This patient's GCS is reasonable and the opiate-like effects seem minimal (no evidence of respiratory depression). However, this patient has received a hefty dose of paracetamol conferring a high risk of hepatic toxicity. The 12 hour delay makes the absorptive effects of charcoal limited and although it would be useful as gastric emptying may be delayed it is not as important in this patient as the paracetamol antidote. Even though the paracetamol level is not provided, he should be treated with N-acetylcysteine without delay.

[Q: 469] OnExamination -
Emergency medicine

A 35-year-old male with a long history of ulcerative colitis is treated for an acute exacerbation which settles following an alteration of his medication. 6 weeks after discharge he is re-admitted with sepsis and his results show:

haemoglobin 10.5 g/dL (11-16)

white cell count $2.0 \times 10^9/L$ (4-11)

platelets $90 \times 10^9/L$ (150-400)

Which one of the following drugs is most likely to be the cause of his pancytopenia?

- 1- Azathioprine
- 2- Mesalazine
- 3- Metronidazole
- 4- Pamidronate
- 5- Prednisolone

Answer & Comments

Answer: 1- Azathioprine

The answer could be either A or B as both cause a pancytopenia although azathioprine is the more common cause. Hence it is a toss up but one would have to go for A.

[Q: 470] OnExamination -
Emergency medicine

A 55-year-old nurse developed bronchospasm and urticaria twenty minutes into surgery under general anaesthesia. The mast cell tryptase concentration confirmed an acute allergic reaction. Later, it transpired that she had developed allergic reactions at her dentist and had developed frequent episodes of wheezing when assisting at sterile procedures.

What is the most likely diagnosis?

- 1- allergy to anaesthetic induction agents
- 2- allergy to local anaesthetic agents
- 3- Latex allergy
- 4- pressure urticaria
- 5- systemic mastocytosis

Answer & Comments

Answer: 3- Latex allergy

This patient developed anaphylaxis during a surgical procedure and it appears that she had problems with allergies during dental treatment and whilst assisting during sterile procedures. This would suggest that she is allergic to latex rather than induction agents or local anaesthesia as latex would be present in all three of the above procedures. Systemic

mastocytosis is a disease which usually affects the elderly and is associated with urticaria pigmentosa, diarrhoea, hypotension, sclerotic bone changes and mast cell infiltration of organs such as spleen, liver kidneys.

[Q: 471] OnExamination -
Emergency medicine

Seventeen of twenty-four passengers on a Nile cruise develop bloody diarrhoea on the third day.

Which of the following organisms is the likely cause?

- 1- Giardia lamblia
- 2- Vibrio cholerae
- 3- Shigella dysenteriae
- 4- Schistosoma mansoni
- 5- Entamoeba histolytica

Answer & Comments

Answer: 3- Shigella dysenteriae

Dysentery is characterised by the passing of frequent (sometimes very frequent) stools, that may contain blood, mucus or pus. Shigella dysenteriae is responsible for bacillary dysentery, a disease most often associated with crowded, unsanitary conditions. Other species of Shigella may produce milder forms of diarrhoeal disease. Dysentery is an oral infection transmitted via faecal contamination of water or food. During the 1-4 day incubation period, penetration of bacteria into the mucosal epithelial cells of the intestine causes an intense irritation of the intestinal wall, producing cramps and a watery, bloody diarrhoea.

[Q: 472] OnExamination -
Emergency medicine

A 40-year-old man presents with acute weakness and palpitations. Investigations reveal:

Sodium	143 mmol/L (137 - 144)
Potassium	8.0 mmol/L (3.5-4.9)
Urea	35 mmol/L (2.5 - 7.5)
Creatinine	450 umol/L (60 - 110)
Bicarbonate	5 mmol/L (20 - 28)

What is the best immediate therapy?

- 1- intravenous calcium gluconate
- 2- intravenous dextrose and insulin
- 3- intravenous sodium bicarbonate
- 4- nebulised salbutamol
- 5- rectal calcium resonium

Answer & Comments

Answer: 1- intravenous calcium gluconate

This patient appears to have acute renal failure with severe acidosis, hyperkalaemia and has palpitations. The patient should be rehydrated, treated with insulin and given bicarbonate, but the immediate treatment particularly in the context of a life threatening arrhythmia would be Calcium gluconate.

[Q: 473] OnExamination -
Emergency medicine

A 24-year-old law student attends with visual loss affecting the right eye. She reports a constant headache for the last 3 months, and absence of menses for 6 months.

On examination her visual acuity in the right eye is 6/24, with slight constriction of the temporal field in that eye but she has no other neurological deficit. She is afebrile and haemodynamically stable.

What is the diagnosis?

- 1- Glaucoma
- 2- Migraine
- 3- Multiple sclerosis
- 4- Pituitary tumour
- 5- Pregnancy

Answer & Comments

Answer: 4- Pituitary tumour

This patient has a pituitary lesion; the history of headache and amenorrhoea suggests a prolactinoma or non functioning tumour. This has been complicated by involvement of the visual pathway, which has precipitated her visual loss. She needs urgent assessment of her pituitary function, imaging of the pituitary gland by MRI scanning. One of the most important investigations to perform would be a serum prolactin. The amenorrhoea would argue against this being retrobulbar neuritis associated with MS and similarly the peripheral visual field constriction would be unusual as a central scotoma and fluctuating visual loss would be more typical.

[Q: 474] OnExamination -
Emergency medicine

An 18 year-old woman presents with an acute pulmonary embolism in the ninth week of pregnancy.

What is the most appropriate treatment for this patient throughout her pregnancy?

- 1- Aspirin
- 2- Intravenous unfractionated heparin
- 3- Subcutaneous low molecular weight heparin
- 4- Subcutaneous unfractionated heparin
- 5- Warfarin

Answer & Comments

Answer: 3- Subcutaneous low molecular weight heparin

Anticoagulation with subcutaneous heparin is recommended in most guidelines with LMWH being a suitable alternative. The latter has the advantage of requiring no monitoring but is a less well established therapy in pregnancy.

She cannot be treated with IV heparin throughout her pregnancy and Warfarin is also contra-indicated due to teratogenicity. Aspirin provides no demonstrable prophylactic value for venous thromboembolism.

[Q: 475] OnExamination -
Emergency medicine

A 40-year-old male presents with a 6 hour history of profuse vomiting and over the last two hours had developed left sided chest pain and dyspnoea. On examination he had a pulse of 110 beats per minute regular and a blood pressure of 168/90 mmHg. On palpation, he had crepitus over the left supraclavicular region and neck, reduced heart sounds and left basal sided crackles plus some dullness to percussion over the right base of the chest.

What is the most likely diagnosis?

- 1- Aortic dissection
- 2- Aspiration pneumonia
- 3- Oesophageal rupture
- 4- Perforated peptic ulcer
- 5- Pneumothorax

Answer & Comments

Answer: 3- Oesophageal rupture

This man has a history of vomiting which had then progressed to chest pain. The most relevant finding on examination is the crepitus over the chest indicating surgical emphysema. The most probable cause is therefore spontaneous rupture of the oesophagus. Mackler's triad (vomiting, chest pain and cervical emphysema) is almost pathognomonic but absent in almost half the cases. The CXR may reveal the surgical emphysema and a gastrografin swallow is diagnostic.

[Q: 476] OnExamination -
Emergency medicine

Which of the following forms of pulmonary embolism is the commonest cause of secondary pulmonary hypertension?

- 1- Air embolism (Caisson's disease)
- 2- Fat embolism
- 3- Massive pulmonary embolism (e.g., saddle embolism)
- 4- Multiple small recurrent pulmonary embolism
- 5- Paradoxical embolism

Answer & Comments

Answer: 4- Multiple small recurrent pulmonary embolism

[Q: 477] OnExamination -
Emergency medicine

A 75-year-old man was admitted after been found collapsed in a garden shed surrounded by a number of empty containers. On clinical examination the patient had small pupils, a heart rate of 50 beats per minute, and was frothing at the mouth.

What is the most likely diagnosis?

- 1- Creosote poisoning.
- 2- Glyphosate poisoning.
- 3- Organophosphorus poisoning.
- 4- Paraquat poisoning.
- 5- Pyrethroid poisoning.

Answer & Comments

Answer: 3- Organophosphorus poisoning.

The patient has cholinergic features with a relative bradycardia, small pupils and increased salivation. This is highly suggestive of organophosphorus poisoning which as an anticholinesterase inhibitor, thus prolonging the effects of acetylcholine. Paraquat is

associated with nausea vomiting and diarrhoea with ulceration. Creosote is a petroleum based substance and would not have such an effect. Glyphosate herbicides produces nausea, vomiting and diarrhoea with a caustic effect in the mouth. Pyrethroid is an insecticide and poisoning is rare but associated with coma, convulsions and pulmonary oedema.

[Q: 478] OnExamination -
Emergency medicine

An 18-year-old woman is admitted after taking drugs at a night-club.

Which of the following features suggest she had taken Ecstasy (MDMA)?

- 1- A pyrexia of 40°C
- 2- hypernatraemia
- 3- hypokalaemia
- 4- metabolic acidosis
- 5- respiratory depression

Answer & Comments

Answer: 1- A pyrexia of 40°C

Hyponatraemia, tachycardia, hyperventilation and hyperthermia are features of the amphetamine MDMA abuse.

[Q: 479] OnExamination -
Emergency medicine

A 27-year-old female presents to the surgical intake with abdominal pain and 5 day history of vomiting. Over the last 3 months she has also been aware of a 6kg weight loss. On examination, she is pale, has a temperature of 38.5 C, blood pressure of 90/60 mmHg and pulse rate of 130 in sinus rhythm. The chest is clear on auscultation but she has a diffusely tender abdomen with no guarding.

Her BM reading is 2.5.

Initial biochemistry is as follows:

Sodium	124 mmol/l	(134 - 144 mmol/L)
Potassium	6.0 mmol/l	(3.5 - 5.5 mmol/L)
Urea	7.5 mmol/l	(3 - 8 mmol/L)
Creatinine	78 µmol/l	(50 - 100 µmol/L)
Glucose	2.0 mmol/l	(3.5 - 6 mmol/L)

What is the probable diagnosis?

- 1- Abdominal migraine
- 2- Acute appendicitis
- 3- Acute cholecystitis
- 4- Addison's disease
- 5- Insulinoma

Answer & Comments

Answer: 4- Addison's disease

This patient has clinical features of hypoadrenal crisis with abdominal pain and vomiting and shock with hypoglycaemia, hyponatremia and hyperkalaemia in keeping with hypoadrenalism. She needs emergency fluid resuscitation, steroid administration, (prior to this urgent cortisol measurement), and careful search for occult infection. One may expect to find features of addison's disease such as oral pigmentation or other autoimmune disease.

[Q: 480] OnExamination -
Emergency medicine

A 70-year-old female who has a history of chronic anxiety presents with a 3 day history of severe left temporal headache radiating from the eye to the scalp. She had also experienced discomfort during eating.

Which one of the following drugs should be given to this patient while awaiting the results of diagnostic tests?

- 1- Acyclovir
- 2- Carbamazepine
- 3- Diclofenac
- 4- Prednisolone

5- Sumatriptan

Answer & Comments

Answer: 4- Prednisolone

The history suggests temporal arteritis irrespective of the history of anxiety and in view of the sight threatening nature of the disease, the patient should be commenced on steroids. Although the differential diagnosis is also trigeminal neuralgia steroids should be used here whilst awaiting diagnostic investigations as temporal arteritis may be sight threatening if left untreated.

[Q: 481] OnExamination -
Emergency medicine

A 16 year-old girl is brought to A+E after having taking drugs at a rave.

Which of the following suggests that she has taking Ecstasy (MDMA)?

- 1- hypernatraemia
- 2- metabolic acidosis
- 3- Pin-point pupils
- 4- Pyrexia
- 5- respiratory depression

Answer & Comments

Answer: 4- Pyrexia

The features of ecstasy overdose include hyperthermia, hypertension, hyponatraemia due to polydipsia associated with SIADH and respiratory alkalosis. Pin-point pupils suggest opiates.

[Q: 482] OnExamination -
Emergency medicine

A 16-year-old girl presents with an acute exacerbation of asthma.

On examination her respiratory rate was 30 per minute, her heart rate was 120 beats per

minute and a peak expiratory flow rate (PEFR) was 30% of the predicted value.

Her blood gas analysis on air shows:

paO₂ 9 kPa (11.3-12.6)

paCO₂ 3.5 kPa (4.7-6.0)

After the administration of oxygen and corticosteroids what is the most appropriate next step in management?

- 1- Intravenous Aminophylline
- 2- Intravenous Salbutamol
- 3- Ipratropium Bromide via oxygen-driven nebuliser
- 4- Salbutamol via oxygen-driven nebuliser
- 5- Salmeterol via breath-actuated inhaler

Answer & Comments

Answer: 4- Salbutamol via oxygen-driven nebuliser

This patient has severe asthma as revealed by the low PEFR, low P02 and signs.

The next stage in the management is the administration of nebulised beta 2 agonists with supplementation of high flow oxygen (minimum of 6L/minute).

Beta 2 agonists can be administered in 15-30 minute intervals if required. Intravenous therapy with beta 2 agonists should only be used if inhaled therapies cannot be reliably administered.

[Q: 483] OnExamination -
Emergency medicine

In adult basic life support the correct ratio of chest compressions to ventilations is:

- 1- 5 to 1
- 2- 8 to 1
- 3- 10 to 1
- 4- 15 to 2
- 5- 30 to 2

Answer & Comments

Answer: 5- 30 to 2

15 compressions to 2 breaths was the recommended ratio regardless of the number of rescuers performing basic life support, but the recent guidelines now suggest 30:2.

[Q: 484] OnExamination -
Emergency medicine

A 45-year-old male is seen in the Emergency Department complaining of cough and dyspnoea. On examination he is disorientated and febrile at 38.5°C. He has a pulse of 100/min and his blood pressure is 85/55 mmHg. He has oxygen saturations of 89% on air and has a respiratory rate of 36/min. Chest x-ray shows left basal consolidation. Results show:

Sodium	140 mmol/l	(133-144)
Potassium	4.0 mmol/l	(3.5-5.5)
Urea	10.2 mmol/l	(3-8)
Creatinine	96 micromol/l	(50-100)

Which of the following is not part of the CURB score?

- 1- Blood urea concentration
- 2- Confusion
- 3- Consolidation on chest-x-ray
- 4- Hypotension
- 5- Tachypnoea

Answer & Comments

Answer: 3- Consolidation on chest-x-ray

The CURB score is calculated by assessment of Core Adverse Prognostic Features which are used in assessment of severity of pneumonia. Two from 4 features indicate a severe pneumonia and hospital admission is advised.

The CURB score is calculated using

1. Confusion abbreviated mental test score < 8

2. Urea > 7mmol/l

3. Respiratory rate > 30/min

4. Blood Pressure Systolic BP < 90 or diastolic BP < 60.

[Q: 485] OnExamination -
Emergency medicine

Which of the following would be expected to reduce maternal mortality when given in eclampsia?

- 1- Insulin and dextrose infusion
- 2- Low dose dopamine infusion
- 3- Magnesium infusion
- 4- Phenytoin infusion
- 5- Salbutamol infusion

Answer & Comments

Answer: 3- Magnesium infusion

Magnesium has been shown to significantly reduce maternal mortality in eclampsia and a favourable outcome may also be expected in pre-eclampsia. None of the other agents has been associated with a reduced mortality in eclampsia.

[Q: 486] OnExamination -
Emergency medicine

A 45-year-old man attends Emergency Department with symptoms suggestive of community acquired pneumonia. On examination he is pyrexial at 38.0°C and has a respiratory rate of 32/min, with a blood pressure of 85/55mmHg.

Which of the following combination of features are not necessarily an indication for urgent hospital admission?

- 1- BP of 85/55 mmHg and respiratory rate of 32/min
- 2- Confusion and BP of 85/55mmHg

- 3- Pyrexia of 38.0oC and serum urea of 7.5 mmol/l
- 4- Respiratory rate of 32 and blood urea of 7.5 mmol/l
- 5- BP of 85/55 mmHg and urea of 7.5 mmol/l

Answer & Comments

Answer: 3- Pyrexia of 38.0oC and serum urea of 7.5 mmol/l

This patient has community acquired pneumonia. The CURB score can be used in the assessment of severity using Core Adverse Prognostic Features which are 2 from 4 of:

- 1. Confusion abbreviated mental test score < 8
- 2. Urea > 7mmol/l
- 3. Respiratory rate > 30/min
- 4. Blood Pressure Systolic BP < 90 or diastolic BP < 60.

Clinical judgement must still however be used particularly if only one feature is present or if there is co-morbidity such as age >50 years, chronic cardiac, respiratory or renal disease.

[Q: 487] OnExamination - Emergency medicine

A known case of chronic obstructive pulmonary disease presents to A & E, distressed and cyanosed. Arterial blood gases reveal a pH 7.2, pO_2 55 mmHg and pCO_2 60 mmHg. He is given high concentration oxygen together with a salbutamol nebulizer. Intravenous hydrocortisone is also given. The patient becomes even worse with poorer breathing effort although pulse oximetry showed SaO_2 of 93%.

What is the cause of patient deterioration?

- 1- Constriction of bronchioles in response to salbutamol nebulizer
- 2- High concentration oxygen administration

- 3- Pulmonary artery relaxation causing mismatch between perfusion and ventilation
- 4- Pulmonary vein relaxation causing mismatch between perfusion and ventilation
- 5- Reaction to IV hydrocortisone

Answer & Comments

Answer: 2- High concentration oxygen administration

Obviously the patient was suffering from hypoxia and hypercapnia as a result of acute exacerbation of COPD. His respiratory centre was solely stimulated by hypoxia. That is why his respiratory effort became less and the condition worsened when he was given high concentration oxygen, depriving him of hypoxic drive.

[Q: 488] OnExamination - Emergency medicine

A 50-year-old lady presented to the Emergency Department with cough and dyspnoea for the past two days. She is previously well. She smokes 20 cigarettes per day.

She has a temperature of 38.3oC and is agitated and confused. Her pulse is 110/min and her blood pressure is 88/60 mmHg. Her oxygen saturation is 89% on air and she has a respiratory rate of 40/min. Chest x-ray shows left basal consolidation. Results show:

Sodium	143 mmol/l	(133-144)
Potassium	3.8 mmol/l	(3.5-5.5)
Urea	9.2 mmol/l	(3-8)
Creatinine	85 micromol/l	(50-100)

Her CURB score is documented and she is admitted to hospital with severe pneumonia.

Which of the following would count towards her CURB score?

- 1- Consolidation on Chest X-Ray

- 2- Oxygen saturation
- 3- Peak expiratory flow rate
- 4- Raised blood urea
- 5- Temperature

Answer & Comments

Answer: 4- Raised blood urea

The CURB score is calculated by assessment of Core Adverse Prognostic Features which are used in assessment of severity of pneumonia. Two from 4 features indicate a severe pneumonia and hospital admission is advised.

The CURB score is calculated using

- 1. Confusion abbreviated mental test score < 8
- 2. Urea > 7mmol/l
- 3. Respiratory rate > 30/min
- 4. Blood Pressure Systolic BP < 90 or diastolic BP < 60.

[Q: 489] OnExamination -
Emergency medicine

In considering the management of convulsions select the correct statement from the list below.

- 1- If the fit lasts longer than 5 minutes, then PR diazepam should be given.
- 2- Phenobarbitone is a useful therapy in school age children.
- 3- Paraldehyde is best given intramuscularly.
- 4- Hypoglycaemia should always be considered.
- 5- When associated with fever, antibiotics should always be given to cover the possibility of meningitis.

Answer & Comments

Answer: 4- Hypoglycaemia should always be considered.

Status epilepticus is defined as continuous convulsion lasting greater than 30 minutes, or the occurrence of serial convulsions between which there is no return of consciousness. It may be generalised (tonic clonic, absent) or partial (simple, complex, or with secondary generalisation). Generalised tonic clonic seizures predominate. There are 3 major sub-types:

- " Prolonged febrile seizures.
- " Idiopathic status epilepticus (no underlying CNS lesion or insult).
- " Symptomatic (long-standing neurological disorder or metabolic abnormality).

The commonest cause in a child less than 3 years is a prolonged febrile seizure. Sleep deprivation and drug withdrawal can also precipitate it. The relationship between neurological outcome and duration of status epilepticus is unknown in children and adults. In the animal model, 60 minutes of constant seizure activity is associated with pathological changes, even when metabolic homeostasis is maintained. Cell death thus results in increased metabolic demands from continually discharging neurones. Vulnerable areas include the hippocampus, the mid to low cerebellum, middle cortical areas, and thalamus. Approximately, 20 minutes of status epilepticus produces regional oxygen sufficiency promoting cell damage and necrosis. This is, therefore, used as the threshold in children. Initial management begins with ABC. Hypoglycaemia should be excluded (if present 5ml/kg of 10% dextrose is given by IV infusion), and blood obtained for full blood count, electrolytes including calcium and magnesium, glucose, creatinine, anticonvulsant levels. Blood and urine may be obtained for toxicology. Arterial blood gases should be done, and consideration given to lumbar puncture.

First line anticonvulsant therapy would be diazepam given IV if possible. If seizures persist then phenytoin may be given as a loading dose followed by an infusion. Phenobarbitone may be used as first line in infants. Paraldehyde can be given as a dilute solution intravenously, or administered rectally or IM. The latter 2 routes can produce tissue damage and sloughing, so these should be reserved for exceptional circumstances.

[Q: 490] OnExamination -
Emergency medicine

A 29-year-old woman presents with a 4 month history of malaise, diarrhoea and a 6kg weight loss. On examination there is lymphadenopathy and oesophageal candidiasis.

What is the likely diagnosis?

- 1- Infectious mononucleosis
- 2- HIV
- 3- Hodgkins lymphoma
- 4- Sarcoid
- 5- Toxoplasmosis

Answer & Comments

Answer: 2- HIV

The absence of night sweats makes a diagnosis of lymphoma unlikely. Toxoplasmosis is not associated with diarrhoea. IM would normally be associated with sore throat, often in a younger patient. Lymphadenopathy is very common in HIV, oesophageal candidiasis results from immunosuppression, weight loss is clearly consistent with the diagnosis, and diarrhoea may result from any number of pathogens in HIV.

[Q: 491] OnExamination -
Emergency medicine

A 55-year-old homeless male was found

stuporose and smelling of alcohol.

Observations in A&E reveal a core temperature of 34°C, a pulse of 50 bpm and blood pressure of 116/80 mmHg. Dipstick urine analysis shows Blood +++. Some of his investigations are listed:

Creatinine 320 µmol/L (60-110)

Gamma GT 40 U/L (10-40)

AST 550 U/L (1-40)

LDH 1500 U/L (10-250)

" Urine microscopy no cells or organisms

What is the most likely cause of the raised serum creatinine concentration?

- 1- Chronic renal failure
- 2- Dehydration
- 3- Hypothermia
- 4- Paracetamol poisoning
- 5- Rhabdomyolysis

Answer & Comments

Answer: 5- Rhabdomyolysis

The elevated serum creatinine is most likely due to Rhabdomyolysis as the patient was found unconscious hypothermic and is likely to have sustained muscle injury. The latter is confirmed by an elevated aspartate aminotransferase and LDH but the normal GGT argues against these being released from the liver.

Rhabdomyolysis is strongly suggested by the fact that urinalysis is strongly positive for blood whereas urine microscopy is negative for red blood cells. The positive urinalysis is caused by myoglobin a muscle protein released during muscle damage this appears in the urine and can cause acute renal failure.

[Q: 492] OnExamination -
Emergency medicine

A 70-year-old woman presented with an acute, severe occipital headache, unsteadiness of her gait and vomiting. She had a history of poorly controlled hypertension. On examination there was nystagmus to the left, ataxia of the left limbs and gait ataxia.

What is the most likely diagnosis?

- 1- acute cerebellar haemorrhage
- 2- basal ganglia haemorrhage
- 3- pontine haemorrhage
- 4- subdural haemorrhage
- 5- temporal lobe haemorrhage

Answer & Comments

Answer: 1- acute cerebellar haemorrhage

Cerebellar hemorrhage: The most common symptoms are of severe nausea and vomiting and ataxia. Headache may be severe. Patients with cerebellar hemorrhage can rapidly become comatose within hours after the onset from herniation, because of its limited space in the posterior fossa

Pontine hemorrhage: There are numerous nuclei located within the pons. Rapidly deteriorating level of consciousness, impaired extraocular movement and extensive sensorimotor deficits are clinical clues to pontine hemorrhage.

Basal Ganglia haemorrhage: Contralateral hemiparesis, hemisensory loss, or hemi-inattention. Aphasia, especially nonfluency and impaired comprehension, is frequently seen if haemorrhage occurs in the posterior limb of the left internal capsule.

[Q: 493] OnExamination -
Emergency medicine

A 42-year-old woman presents with an acute attack of asthma. She is able to speak in short

sentences.

Her respiratory rate is 28 breaths per minute and the peak expiratory flow rate 120L/min (predicted 480 L/min).

What is the most appropriate treatment for this patient?

- 1- Intravenous aminophylline.
- 2- Intravenous salbutamol
- 3- Nebulized salbutamol
- 4- Oral salbutamol
- 5- Oral theophylline

Answer & Comments

Answer: 3- Nebulized salbutamol

This patient has features of acute severe asthma, and should be given oxygen, steroids and nebulised salbutamol as immediate treatment. Although the PFR is less than 33% of predicted normal (feature of life threatening attack), we do not know what her previous best is. It could be low eg 240L/min. If it had been a life threatening attack, nebulised ipratropium and iv aminophylline, salbutamol or terbutaline should be given. The guidelines do not specify a preference. This is another clue that the answer should be nebulized salbutamol.

[Q: 494] OnExamination -
Endocrinology

A 20-year-old man with asthma was found to be hypertensive. Investigations revealed:

Serum sodium 144 mmol/L (137-144)

Serum potassium 2.4 mmol/L (3.5-4.9)

Serum bicarbonate 30 mmol/L (20-28).

Which one of the following is the most likely diagnosis?

- 1- Bartter's syndrome
- 2- Coarctation of the aorta
- 3- Congenital Adrenal Hyperplasia
- 4- Conn's Syndrome
- 5- Inhaled Salbutamol therapy

Answer & Comments

Answer: 4- Conn's Syndrome

This is a tough question as a number of answers are possible. This young asthmatic has a hypokalaemic hypertension and I'm assuming that his hypertension is sustained. This would therefore suggest a secondary cause which may be either hyperaldosteronism or pseudohyperaldosteronism. A rare CAH (11-beta hydroxysteroid dehydrogenase (11-BHSD) deficiency) may be responsible for hypokalaemic hypertension and the presentation is variable ranging from birth to adulthood but typically birth. Bartter's syndrome is not associated with hypertension. Conn's syndrome is usually found in middle aged patients and would be unusual in a patient of this age but even so is probably the best answer here. Liquorice ingestion could again fit this picture but would again be somewhat unusual in this patient. Salbutamol may cause hypokalaemia particularly when given via nebuliser or particularly iv but should not produce hypertension.

[Q: 495] OnExamination -
Endocrinology

A 33-year-old female presents with a one year history of galactorrhoea and amenorrhoea. She informs you that she does not want to become pregnant. On examination there is galactorrhoea to expression and visual fields are normal to confrontation.

Investigations confirm the diagnosis of a macroprolactinoma, with a prolactin concentration of 10,500 mu/l (50-500) and MRI of the pituitary revealing a 1.5 cm tumour with some suprasellar extension.

What is the most appropriate treatment for this woman?

- 1- Cabergoline therapy
- 2- Combined oral contraceptive
- 3- Pituitary surgery
- 4- Somatostatin analogue therapy
- 5- Stereotactic pituitary irradiation

Answer & Comments

Answer: 1- Cabergoline therapy

This young woman has a macroprolactinoma and these are exquisitely sensitive to dopamine agonist therapy and rapid tumour reduction with restoration of menses and cessation of galactorrhoea expected. Pituitary surgery is rarely required in prolactinomas and is generally reserved for patients intolerant or resistant to dopamine agonist therapy. Even with large tumours that compress the chiasm, these can be treated with dopamine agonists with rapid reduction in size and relief of pressure. The fact that she does not want to become pregnant is a bit of an irrelevance. One would still treat her with dopamine agonist therapy and suggest use of appropriate contraception which could include the OCP.

[Q: 496] OnExamination -
Endocrinology

Which of the following statements concerning transferrin is correct?

- 1- Transferrin levels fall during pregnancy
- 2- Transferrin binds ferrous iron
- 3- In the absence of anaemia, transferrin is 80% saturated with iron
- 4- Levels are elevated in haemochromatosis
- 5- Levels are elevated in patients on the oral contraceptive pill

Answer & Comments

Answer: 5- Levels are elevated in patients on the oral contraceptive pill

Pregnancy and the OCP both increase transferrin levels. Iron is carried in the blood bound to transferrin. Fe²⁺ (ferrous iron) is oxidised to Fe³⁺ (ferric iron) by caeruloplasmin to bind to transferrin which is about one third saturated with iron. The saturation of TIBC (plasma iron concentration/TIBC x 100) is used as a measure of iron stores. A value below 16% is indicative of iron deficiency. The transferrin level and the TIBC rise in iron deficiency. Pregnancy and the OCP both increase transferrin levels. Whereas transferrin and TIBC fall in iron overload, percentage saturation is increased in haemochromatosis.

[Q: 497] OnExamination -
Endocrinology

A 55-year-old male presents with anorexia and weight loss of 12 months duration. Over this year he has had two deep vein thromboses and had the last whilst his INR was 2. He remains on long-term warfarin therapy with an INR above 2.6. Examination reveals that he is pigmented and has a postural drop in his blood pressure of 15 mmHg.

Investigations are as follows:

sodium concentration 131 mmol/l

potassium 5.0 mmol/l

INR 3.0

A Short synacthen test reveals a baseline cortisol concentration at time 0 of 120 nmol/l which rises to 155 nmol/l after 30 minutes (Normal response >550 nmol/l).

Which single diagnosis would explain this patient's illness?

- 1- Addison's disease
- 2- Anti-phospholipid syndrome
- 3- Autoimmune Polyendocrine Syndrome (Schmidt's disease)
- 4- Protein S deficiency
- 5- Pituitary infarction

Answer & Comments

Answer: 2- Anti-phospholipid syndrome

With a history of recurrent DVT and confirmed hypoadrenalism this patient is likely to have the antiphospholipid syndrome. Antiphospholipid syndrome is a primary diagnosis or may co-exist with SLE. Anti-Cardiolipin antibodies or Lupus anticoagulant may be present. It is associated with arterial and venous thrombosis and has a predilection for the adrenal veins causing adrenal infarction with consequent hypoadrenalism. Addison's disease is an autoimmune phenomenon and is not associated with DVT. The pigmentation (due to increased ACTH in hypoadrenalism) would exclude pituitary infarction as the cause of the hypoadrenalism. Hypoadrenalism is not associated with protein S deficiency. Autoimmune Polyendocrine syndrome is associated with hypothyroidism, type 1 diabetes, addison's disease.

[Q: 498] OnExamination -
Endocrinology

A 21-year-old woman is known to suffer from anorexia nervosa.

Which of the following metabolic disturbances would be a characteristic finding?

- 1- a decrease in Cortisol levels
- 2- an increase in LH levels
- 3- hyperkalaemia
- 4- impaired glucose tolerance
- 5- raised androgen levels

Answer & Comments

Answer: 4- impaired glucose tolerance

Malnutrition is another cause of diabetes. (Can you name the others? ... Type 1 and Type 2 OK ... but what about gestational or post pancreatitis / pancreatectomy ... do you know the others?)

Cortisol and growth hormone levels are elevated.

LH and FSH would be low and LH response to LHRH is impaired when weight loss is severe.

Hypokalaemia (not hyperkalaemia may be seen). Also there may be hypoalbuminaemia, anaemia, leukopenia, and raised serum carotene.

[Q: 499] OnExamination - Endocrinology

Causes of hypoadrenalism include:

- 1- Hughes' syndrome (anti-phospholipid antibody)
- 2- MEN type 2a
- 3- VonHippel-Lindau
- 4- Pendred's syndrome
- 5- McArdle's syndrome

Answer & Comments

Answer: 1- Hughes' syndrome (anti-phospholipid antibody)

The anti-phospholipid syndrome is one of the commoner causes of Hypoadrenalism and

may precipitate adrenal infarction and haemorrhage through adrenal vein thrombosis.

[Q: 500] OnExamination - Endocrinology

Which ONE of the following concerning Insulin is correct?

- 1- acts via a similar mechanism as steroid receptors
- 2- causes an increased glucose-protein transport on the endoplasmic reticulum
- 3- can be detected in the lymph
- 4- interacts with the nuclear membrane
- 5- is synthesised in the alpha cells of islets of Langerhans

Answer & Comments

Answer: 3- can be detected in the lymph

a-Cell surface receptors.

Insulin binding to its receptor results in receptor autophosphorylation on tyrosine residues and the tyrosine phosphorylation of insulin receptor substrates (IRS-1, IRS-2 and IRS-3) by the insulin receptor tyrosine kinase.

[Q: 501] OnExamination - Endocrinology

Which of the following is not a feature of Zinc deficiency?

- 1- dwarfism
- 2- geophagia
- 3- hepatosplenomegaly
- 4- hypertelorism
- 5- hypogonadism

Answer & Comments

Answer: 4- hypertelorism

Zinc deficiency is associated with dwarfism, hypogonadism, hepatosplenomegaly, rough and dry skin, mental lethargy and geophagia. Zn supplementation has also been shown to improve neuropsychological function in Chinese children, and Zn deficiency is associated with adverse pregnancy outcomes.

[Q: 502] OnExamination - Endocrinology

Which of the following is correct concerning Nitric Oxide:

- 1- Is synthesised principally by the vascular smooth muscle
- 2- Acts via cAMP as the second messenger
- 3- Is manufactured from Glycine
- 4- Is inactivated by superoxide dismutase
- 5- Inhibits platelet aggregation

Answer & Comments

Answer: 5- Inhibits platelet aggregation

Nitric Oxide is a free radical that is produced from L-arginine by nitric oxide synthase in the vascular endothelium. It is anti-atherogenic, causing vasorelaxation, inhibiting platelet aggregation and foam cell formation.

[Q: 503] OnExamination - Endocrinology

Primary hyperparathyroidism may occur in association with the following conditions

- 1- Chronic renal failure
- 2- Vitamin D deficiency
- 3- Gastrinoma
- 4- Autoimmune polyendocrine syndrome
- 5- Sjogren's syndrome

Answer & Comments

Answer: 3- Gastrinoma

The association of primary hyperparathyroidism and a gastrinoma would suggest a diagnosis of multiple endocrine neoplasia type 1. CRF causes secondary or tertiary hyperparathyroidism, with vit D deficiency causing secondary hyperparathyroidism. There is no association with Sjogren's.

[Q: 504] OnExamination - Endocrinology

Which of the following techniques would be most useful in the differential diagnosis between ectopic Cushing's syndrome and pituitary dependent Cushing's disease.

- 1- Urine free cortisol
- 2- High dose Dexamethasone suppression test
- 3- ACTH concentrations
- 4- Inferior petrosal sinus sampling
- 5- CRF test

Answer & Comments

Answer: 4- Inferior petrosal sinus sampling

Inferior petrosal sinus sampling with an elevated central ACTH concentration compared with the peripheral value is the most valuable test in the differential diagnosis of either Cushing's disease or ectopic Cushing's syndrome. The other tests are far less useful in comparison.

[Q: 505] OnExamination - Endocrinology

Which of the following suggests a poorer prognosis for thyroid cancer.

- 1- Papillary thyroid cancer with cervical node involvement.
- 2- Male sex.
- 3- Age less than 30.
- 4- Cold nodule on thyroid uptake scan
- 5- High TSH concentration

Answer & Comments

Answer: 2- Male sex.

Factors that suggest a poor prognosis in thyroid cancer include increasing age, male sex, poorly differentiated histological features and distant spread.

[Q: 506] OnExamination - Endocrinology

A 40-year-old man is undergoing investigation for acromegaly. MRI of the pituitary fossa is normal, but a routine chest x-ray reveals a large centrally based mass. The patient is a non-smoker.

What is the most likely type of this lung tumour?

- 1- Squamous cell
- 2- Small cell
- 3- Carcinoid
- 4- Large cell
- 5- Adenocarcinoma

Answer & Comments

Answer: 3- Carcinoid

A central based mass in a non-smoker showing clinical evidence of neuroendocrine cell origin is consistent with a carcinoid and surgery offers a very high chance of cure.

[Q: 507] OnExamination - Endocrinology

During routine investigation of a healthy couple for primary subfertility, semen analysis reveals azoospermia. On examination of the male there are no abnormalities on general examination and testicular examination shows a normal testicular volume.

Investigations reveal:

LH 5.1 iu/l (2-10)

FSH 4.3 iu/l (2-10)

Testosterone 15.3 nmol/l (9-30)

Which of the following is the most likely cause of his azoospermia?

- 1- Androgen insensitivity
- 2- Genital tract obstruction
- 3- Idiopathic testicular failure
- 4- Kallman's Syndrome
- 5- Sperm autoimmunity

Answer & Comments

Answer: 2- Genital tract obstruction

The normal FSH, testosterone would exclude a primary testicular cause of the azoospermia and therefore would suggest obstruction such as agenesis of the vas as seen in cystic fibrosis.

[Q: 508] OnExamination - Endocrinology

A 36-year-old male with insulin-dependent diabetes mellitus of three years duration presented with decreased libido and erectile dysfunction since diagnosis. No abnormalities were noted on genital examination. Investigations revealed:

plasma testosterone 6.0 nmol/L (9 - 35)

plasma follicle stimulating hormone 1.0 u/L (1-8)

Which of the following investigations is most appropriate next step?

- 1- autonomic function testing
- 2- Doppler studies of penile artery
- 3- Nerve conduction studies
- 4- Serum ferritin
- 5- Serum prolactin

Answer & Comments

Answer: 4- Serum ferritin

This IDDM patient appears to have hypogonadotropic hypogonadism (HH) as

reflected by low testosterone and low FSH. The combination is compatible with a diagnosis of haemochromatosis and measuring ferritin would be a reasonable investigation. Haemochromatosis typically causes hypogonadotrophic hypogonadism as a consequence of the ferritin deposition within the pituitary rather than primary testicular dysfunction. Autonomic nerve dysfunction is one of the commoner causes of impotence in a diabetic but in this case is not the cause of his HH. For similar reasons, both nerve conduction studies and dopplers are irrelevant. Prolactin would be a sensible measurement but probably if you were looking to confirm a diagnosis that incorporates the diabetes as well, Ferritin would be the investigation of choice.

[Q: 509] OnExamination - Endocrinology

A 55-year-old female undergoes a DEXA scan which reveals a bone mineral density T score of -2.55 at the hip and lumbar spine.

Which of the following may contribute to such a result?

- 1- Acromegaly
- 2- Delayed menopause
- 3- Hypothyroidism
- 4- Myeloma
- 5- Obesity

Answer & Comments

Answer: 4- Myeloma

This patient has osteoporosis as defined by her abnormally low T score. Endocrine diseases associated with osteoporosis are Cushing's disease, vitamin D deficiency, thyrotoxicosis and hypogonadism. Myeloma and lymphoma are also associated with reduced BMD. Other associates include rheumatoid arthritis, renal failure, corticosteroids, early menopause, slender

habitus, smoking, lack of exercise, family history, age/sex and excess alcohol.

[Q: 510] OnExamination - Endocrinology

Which of the following is NOT associated with hyponatraemia and hyperkalaemia?

- 1- Acute hypoadrenalism
- 2- Carbenoxolone therapy
- 3- Co-Amilorfruse therapy
- 4- Congestive cardiac failure.
- 5- Type IV renal tubular acidosis

Answer & Comments

Answer: 2- Carbenoxolone therapy

Carbenoxolone therapy may be associated with hypokalaemia and salt retention due to pseudohypoaldosteronism through inhibition of the enzyme 11 beta Hydroxysteroid dehydrogenase. Type IV renal tubular acidosis is associated with hyporeninaemic hypoaldosteronism and both hyponatraemia and hyperkalaemia can occur. Hypoadrenalism is associated with hyperkalaemia and hyponatraemia as is Cardiac failure, hepatic and renal failure. Co-amilofruse the combination of amiloride and furosemide may also produce this biochemical picture.

[Q: 511] OnExamination - Endocrinology

Which of the following is a glycoprotein hormone?

- 1- Growth hormone releasing hormone
- 2- Cortisol
- 3- Thyrotropin releasing hormone (TRH)
- 4- Thyrotropin (TSH)
- 5- Oxytocin

Answer & Comments

Answer: 4- Thyrotropin (TSH)

Thyrotropin is glycosylated, cortisol is a steroid hormone and the others are peptide hormones/neuropeptides which as a group are rarely glycosylated.

[Q: 512] OnExamination - Endocrinology

A 25-year-old nurse presents with fatigue, tremulousness and a 7kg weight loss over the past one month. On examination she has a tachycardia but no other abnormal findings. Thyroid function tests show:

free thyroxine 40 pmol/L (10-23)

TSH <0.01 mU/L (0.5-5.0)

Which one of the following would confirm the diagnosis of thyroiditis?

- 1- Elevated free T3 concentration
- 2- Failure of TSH to rise following IV TRH
- 3- High titre of thyroid peroxidase antibodies
- 4- Negligible 4 hour radioiodine thyroid uptake
- 5- Raised ESR

Answer & Comments

Answer: 4- Negligible 4 hour radioiodine thyroid uptake

This test result and symptoms may be consistent with thyroiditis such as DeQuervain's and an elevated ESR with negligible uptake of RAI (as thyroid cells are attacked and hence release stored T4 but fail to synthesise T4) would be expected. In Graves disease you would expect homogenous uptake whereas a toxic nodule would show a solitary area of high uptake. Antibodies such as TPO, and TSH receptor antibodies are found in autoimmune thyroid disease. The TRH test is seldom used except in thyroid oncology.

[Q: 513] OnExamination - Endocrinology

A 24-year-old female presents with a two week history of polyuria and polydipsia together with frequent nocturia.

Investigations show

Serum Sodium 144 mmol/l (133-144)

Serum Potassium 3.3 mmol/l (3.5-5)

Serum Calcium 2.6 mmol/l (2.2-2.6)

Plasma glucose 6.8 mmol/l (3.5-5.5)

Serum Osmolality 310 mosmol/l (275-295)

What is the diagnosis?

- 1- Diabetes Insipidus
- 2- Diabetes Mellitus
- 3- Drug abuse
- 4- Primary hyperparathyroidism
- 5- Primary polydipsia

Answer & Comments

Answer: 3- Drug abuse

This patient has polyuria and polydipsia of relative recent onset and has an elevated plasma osmolality with a high calcium and glucose concentration. These features would be unlikely in DI and are more in keeping with thiazide diuretic abuse - high calcium, glucose and hypokalaemia. Similarly, the serum osmolality would be low in association with primary polydipsia. There may be plenty of variations purely by alteration of the biochemistry of this question in the exam.

[Q: 514] OnExamination - Endocrinology

Which of the following is true of radioactive iodine (¹³¹I) therapy?

- 1- Causes hypothyroidism in 90% of treated patients within 3 months
- 2- Causes a deterioration in ophthalmopathy in patients with Graves disease

- 3- Is associated with a subsequently increased risk of infertility
- 4- Is associated with an increased risk of thyroid lymphoma
- 5- Is the preferred treatment in amiodarone induced thyrotoxicosis

Answer & Comments

Answer: 2- Causes a deterioration in ophthalmopathy in patients with Graves disease

RAI is associated with the induction of hypothyroidism in the majority of subjects by 3 months (70%) with 10% failing at the first dose at about 18 months. It may precipitate deterioration in ophthalmopathy in patients with Graves. There is no evidence of either increased risk of infertility or lymphoma after RAI with evidence suggesting that it is quite safe. Withdrawing amiodarone is the preferred treatment in amiodarone induced thyrotoxicosis and often the iodine uptake would be low in these patients making ¹³¹I therapy unhelpful.

[Q: 515] OnExamination - Endocrinology

A 17-year-old boy is brought to clinic as his parents are concerned regarding possible delayed puberty. He was otherwise well, played sports regularly and academic performance was good. His height was 1.7m and weight was 70kg.

On examination he had small penis and testes, absent pubic hair, but no other abnormalities. Investigations revealed:

Serum testosterone 4 nmol/L (9-35)
 Plasma follicle stimulating hormone (FSH) 1 U/L (1-7)
 Plasma luteinising hormone (LH) 1 U/L (1-10)
 Plasma prolactin 300 mU/L (<450)
 Plasma TSH 2 mU/L (0.5-5)

Which one of the following is the most likely cause?

- 1- Constitutional delay
- 2- Hypopituitarism
- 3- Hypothyroidism
- 4- Kallman's syndrome
- 5- Klinefelter's syndrome

Answer & Comments

Answer: 4- Kallman's syndrome

The low FSH and LH, together with the low testosterone, suggests a hypogonadotrophic hypogonadism. We know that there is no mental retardation, and we are told that physical examination is normal and sense of smell would usually not be tested.

Consequently a diagnosis of Kallman's is suggested. We are not told of a family history of growth delay, thus this is unlikely to be constitutional delay. The TSH is normal, making hypothyroidism unlikely and this together with the normal prolactin make hypopituitarism most unlikely.

[Q: 516] OnExamination - Endocrinology

A 29-year-old female presents with headaches. She is noted to be hypertensive with a blood pressure of 180/100 mmHg and initial investigations reveal a hypokalaemia of 2.9 mmol/l. On closer questioning she is found to consume a large quantity of licquorice.

Inhibition of which enzyme is responsible for the pseudohyperaldosteronism associated with Liquorice.

- 1- 5 alpha-reductase
- 2- 21 Hydroxylase
- 3- 11 betaHydroxysteroid dehydrogenase (11 bHSD)
- 4- 17 alpha hydroxylase (17aOH)
- 5- 11 beta hydroxylase (11 bOH)

Answer & Comments

Answer: 3- 11 betaHydroxysteroid dehydrogenase (11 bHSD)

11bHSD is responsible for the conversion of cortisol to the inactive cortisone, preventing activation of the mineralocorticoid receptor by cortisol but permitting activation by aldosterone. Both Liquorice and carbenoxolone inhibit 11bHSD and produce pseudohyperaldosteronism with hypertension and hypokalaemia yet appropriately low renin and aldosterone concentrations. Much research is focussed upon this enzyme of late.

[Q: 517] OnExamination - Endocrinology

A 60-year-old man is admitted with a productive cough with flecks of blood in his sputum. Chest X-ray reveals a mass lesion in the right mid zone.

Investigations reveal:

sodium 110 mmol/L (137-144)

potassium 4.0 mmol/L (3.5-4.9)

bicarbonate 24 mmol/L (20-28)

urea 3.0 mmol/L (2.5-7.5)

creatinine 80 umol/L (60-110)

Which of the following findings suggest a diagnosis of the syndrome of inappropriate ADH (SIADH) secretion?

- 1- Presence of ascites
- 2- Plasma osmolality 236 mosmol/kg (278-305)
- 3- urine flow rate 20 mL/hour
- 4- urine osmolality 250 mosmol/kg (350-1000)
- 5- urine sodium 110 mmol/L

Answer & Comments

Answer: 5- urine sodium 110 mmol/L

The serum osmolality associated with hyponatraemia is generally low and so would

not in itself suggest SIADH. However, in the context of the low plasma osmolality a high urine osmolality (2x that of the plasma osmolality) with an elevated urine sodium (above 20 mmol/l) is suggestive of this diagnosis.

[Q: 518] OnExamination - Endocrinology

A 54-year-old male who is a HGV driver and has a 10 year history of type 2 diabetes is seen on annual review. His glycaemic control is poor with a HBA1c of 10.5% on maximal oral hypoglycaemic therapy. You suggest switching to insulin but he refuses to do this as he would lose his HGV licence.

He also refuses to inform the DVLA himself, what is the most appropriate action in this case?

- 1- Continue to review patient in clinic and accept that he continues to drive.
- 2- Discharge him from clinic as there is nothing more that you can do.
- 3- Inform the DVLA even if the patient withholds his consent.
- 4- Inform his employer that he must stop driving and suggest administrative work.
- 5- Tell his next of kin that they should inform the DVLA that he is no longer fit to drive.

Answer & Comments

Answer: 1- Continue to review patient in clinic and accept that he continues to drive.

In this particular case, the patient has poor glycaemic control but otherwise has no features whatsoever that preclude him from driving such as retinopathy, neuropathy or hypoglycaemic episodes. You cannot therefore force this patient to switch to insulin and neither can you stop him driving. He will continue to regular a medical every three years for his continued HGV licence.

[Q: 519] OnExamination -
Endocrinology

Which of the following features would be expected on lipid analysis in a 57-year-old female with two year history of primary biliary cirrhosis?

- 1- A lipaemic appearance of the serum would be expected.
- 2- is treated with clofibrate therapy
- 3- is characteristically associated with tendon xanthomas
- 4- is characteristically associated with palmar xanthomas
- 5- No evidence of a dyslipidaemia would be expected with this short a duration of disease

Answer & Comments

Answer: 4- is characteristically associated with palmar xanthomas

In prolonged cholestasis features include: increased serum cholesterol, a moderate increase in triglyceride, the serum is not lipaemic, and reduced HDL levels. Clinical features include: palmar xanthomas; tuberous xanthomas (particularly on extensor surfaces); tendinous xanthomas are rare. Xanthomas usually only occur if cholestasis has persisted for more than 3 months sometimes fat deposits may involve bone and peripheral nerves.

[Q: 520] OnExamination -
Endocrinology

Which of the following statements is correct concerning the relationship between Type 2 Diabetes and colonic cancer?

- 1- The increased risk of colorectal cancer in diabetes is related to BMI
- 2- The increased risk of colorectal cancer in diabetes is related to total cholesterol

- 3- Increased concentrations of C-peptide are a marker of increased colorectal cancer risk
- 4- Insulin treatment increases recurrence-free survival after treatment of colonic cancer
- 5- Type 1 diabetes has similar risks of colonic cancer as does type 2 diabetes

Answer & Comments

Answer: 3- Increased concentrations of C-peptide are a marker of increased colorectal cancer risk

Type 2 diabetes is associated with a 40-60% increase in the risk of cancer of the large bowel. This increase is linked to changes in HbA1c. Type 2 diabetes is associated with significantly higher rates of overall mortality and reduced disease free and recurrence free survivals after chemotherapy/radiotherapy, and insulin has not been shown to have any effects on mortality. No association has been found between colonic malignancy and type 1 diabetes, nor gestational diabetes. For a discussion see BMJ 2005;330:551-2.

[Q: 521] OnExamination -
Endocrinology

A 25-year-old female presents with weight gain, oligomenorrhoea and primary infertility. She has a history of bipolar disorder for which she takes Lithium. On examination she has a BMI of 32 kg/m².

Investigations reveal:

Free T₄ 6.4 nmol/l (9-23)

TSH 42 mu/l (0.5 - 5)

Prolactin 980 mu/l (50-450)

What is the most appropriate treatment for this patient?

- 1- Cabergoline
- 2- Cabergoline plus thyroxine
- 3- Metformin
- 4- Thyroxine

5- Stop Lithium

Answer & Comments

Answer: 4- Thyroxine

This patient has primary hypothyroidism which would explain the increasing weight and the associated hyperprolactinaemia. The latter occurs as a consequence of reduced dopaminergic tone. The most appropriate treatment for her would be thyroxine which would through euthyroidism be expected to normalise prolactin concentration. In turn this may improve weight, menstrual function and fertility.

[Q: 522] OnExamination - Endocrinology

A 60 year female presents with vague aches and pains and has a family history of osteoporosis. She is 10 years post-menopausal but has not taken any female HRT. Dual energy X-ray absorptiometry (DEXA) is requested.

Which of the following values of bone mineral density measured by DEXA would signify osteopaenia at a measured site?

- 1- A T score of -2.6
- 2- A T score of -1.8
- 3- A Z score of -2.0
- 4- A z score of -1.5
- 5- A T score of -0.9

Answer & Comments

Answer: 2- A T score of -1.8

Osteopaenia is defined as a T score of between -1 and -2.5 standard deviations below the bone mineral density of a young female. Osteoporosis is defined as <-2.5 SD. These measurements are important as they signify a greatly increased risk of fracture. Z scores refer to the bone mineral density

compared with that of a 'normal' age matched subject.

[Q: 523] OnExamination - Endocrinology

A 60 year female presents with vague aches and pains and has a family history of osteoporosis. She is 10 years post-menopausal but has not taken any female HRT. Dual energy X-ray absorptiometry (DEXA) is requested.

Which of the following values of bone mineral density measured by DEXA would signify osteopaenia at a measured site?

- 1- A T score of -2.6
- 2- A T score of -1.8
- 3- A Z score of -2.0
- 4- A z score of -1.5
- 5- A T score of -0.9

Answer & Comments

Answer: 2- A T score of -1.8

Osteopaenia is defined as a T score of between -1 and -2.5 standard deviations below the bone mineral density of a young female. Osteoporosis is defined as <-2.5 SD. These measurements are important as they signify a greatly increased risk of fracture. Z scores refer to the bone mineral density compared with that of a 'normal' age matched subject.

[Q: 524] OnExamination - Endocrinology

Which ONE of the following is true concerning Antidiuretic hormone (ADH)?

- 1- Carbamazepine potentiates its release
- 2- Ethanol potentiates its release
- 3- It circulates in the blood bound to neurohypophysin
- 4- It is a cyclic octapeptide

5- It is synthesised in the posterior pituitary

Answer & Comments

Answer: 1- Carbamazepine potentiates its release

ADH is a nonapeptide manufactured in the paraventricular and supra-optic nuclei of the hypothalamus and released from the posterior pituitary. It acts on the collecting ducts improving water permeability and hence water retention. Carbamazepine as well as other agents such as thiazides and SSRIs may potentiate its release. Ethanol usually inhibits release.

[Q: 525] OnExamination - Endocrinology

A 47-year-old schoolteacher presents to her GP with fatigue. The GP noted her to be hypercalcaemic with an albumin of 39 g/l, globulin 28g/l and Ca ++ of 2.80.

Which of the following statements is true?

- 1- 24 hour urinary calcium assay is of no use at all.
- 2- Primary hyperparathyroidism will be diagnosed only if the PTH is at least three times the normal range.
- 3- Modern assays for PTH and PTHrP should may cross-react so that assays are unreliable.
- 4- The patient could have surgery if renal stones are found on ultrasound
- 5- The most likely diagnosis is myeloma.

Answer & Comments

Answer: 4- The patient could have surgery if renal stones are found on ultrasound

24hr urinary calcium may be useful if used in comparison to the serum calcium in order to distinguish familial hypocalciuric hypercalcaemia from primary hyperparathyroidism. PTH may be less than

twice the upper limit of normal in primary hyperparathyroidism. Several indications for surgery exist including calcium >1mg/dl above upper normal limit, greater than 30% decline in renal function, renal stones, Age<50, unwillingness of patient to follow advice of medical surveillance. Myeloma is unlikely given the normal immunoglobulins.

[Q: 526] OnExamination - Endocrinology

Osteomalacia may be expected in

- 1- Sarcoidosis
- 2- Auto-immune adrenalitis
- 3- Pseudo-hypoparathyroidism
- 4- Pernicious anaemia
- 5- Mercury poisoning

Answer & Comments

Answer: 5- Mercury poisoning

Osteomalacia may occur with vitamin D deficiency. Mercury poisoning or any heavy metal poisoning causes an acquired Fanconi syndrome with distal renal tubular acidosis.

[Q: 527] OnExamination - Endocrinology

A 73-year-old female is diagnosed with Cushing's disease.

Which of the following is correct?

- 1- Adrenalectomy would be the treatment of choice.
- 2- op-DDD is a treatment if unfit for surgery
- 3- Ketoconazole may be used as a treatment if unfit for surgery
- 4- Recurrence of Cushing's disease after transphenoidal surgery is less than 5%
- 5- yttrium implantation is an effective treatment

Answer & Comments

Answer: 3- Ketoconazole may be used as a treatment if unfit for surgery

Transphenoidal hypophysectomy/adenomectomy would be the initial treatment of choice. Laparoscopic adrenalectomy would be advised where pituitary surgery has failed. Ketoconazole may be an effective treatment for patients unfit for surgery. opDDD is used for adrenal carcinomas. Yttrium implantation has been abandoned even for acromegaly as is pretty useless. The recurrence rate for Cushing's disease after surgery is of the order of 20-30% in most series and depends on the size of the tumour with macroadenomas having a higher rate of relapse.

[Q: 528] OnExamination - Endocrinology

A 28-year-old female is referred with a three month history of tiredness and weakness. On examination, pulse is 82 bpm and blood pressure is 128/72 mmHg. No specific abnormalities are evident on examination of the cardiovascular, respiratory, abdominal or neurological systems. Investigations reveal:

Serum Sodium 142 mmol/l (134-144)

Serum Potassium 3.0 mmol/l (3.5-5)

Serum Urea 4.2 mmol/l (3-8)

Serum Creatinine 82 µmol/l (50-100)

Serum Chloride 73 mmol/l (95-107)

Plasma Glucose 5.5 mmol/l (3.5-5.5)

Urinary chloride 60 mmol/l (20 - 350)

Which of the following is the likely diagnosis?

- 1- Bartter's syndrome
- 2- Conn's syndrome
- 3- Drug ingestion
- 4- Liddle's syndrome
- 5- Non classical Congenital adrenal hyperplasia

Answer & Comments

Answer: 3- Drug ingestion

This young woman has hypokalaemia and hypochloraemia. The normal blood pressure would exclude a diagnosis of Conn's, CAH, or Liddle's syndrome (apparent mineralocorticoid excess). Similarly, drug ingestion associated with hypokalaemia - licquorice/carbenoxolone - is again associated with hypertension (and low urinary chloride < 20 mmol/L). Bartter's syndrome is a rare, recessive condition associated with weakness, lethargy and growth retardation and is found in youngsters. Hypokalaemic hypochloareamic alkalosis is seen in the condition but symptoms would be more apparent at a much younger age than this woman. If Gitelman's syndrome were offered then that would be a better option. Therefore, the most likely diagnosis as the symptoms have arisen only over the last three months and no other features are apparent on examination is diuretic abuse.

[Q: 529] OnExamination - Endocrinology

A previously fit 47-year-old male presents with lower back pain from a vertebral collapse due to osteoporosis.

Which of the following investigations would be the most appropriate for this man?

- 1- oestrogen concentration
- 2- prostate-specific antigen concentration
- 3- prolactin concentration
- 4- testosterone concentration
- 5- thyroid function tests

Answer & Comments

Answer: 4- testosterone concentration

Osteoporosis in a young male would be unusual. Any symptoms or features of hypogonadism or hypercalcaemia should be

elicited. Hyperprolactinaemia causes hypogonadism so a testosterone concentration would be far more relevant. Hyperthyroidism would need to be present for a considerable length of time before producing osteoporosis. Hypogonadism often goes unnoticed. Prostate malignancy does not cause osteoporosis.

[Q: 530] OnExamination - Endocrinology

The thyroid hormone receptor is:

- 1- A gated ion channel
- 2- A cell surface receptor
- 3- A cytoplasmic protein
- 4- A G-protein coupled receptor
- 5- A nuclear receptor

Answer & Comments

Answer: 5- A nuclear receptor

The thyroid hormone receptor is a nuclear receptor. When it binds T3 it is able to bind to the thyroid hormone response element (TRE) in the promoter region of thyroid hormone responsive genes and initiates transcription.

[Q: 531] OnExamination - Endocrinology

Which ONE of the following is a recognised feature of achondroplasia?

- 1- Autosomal recessive inheritance
- 2- May be diagnosed radiologically at birth
- 3- Increased liability to pathological fractures
- 4- Shortened spine
- 5- Subfertility

Answer & Comments

Answer: 2- May be diagnosed radiologically at birth

ACHONDROPLASIA is an autosomal dominant condition and one of the commonest forms of inherited dwarfism. Epiphyseal dysplasia - thin zone of cartilage cells, diminished columnar arrangement short thick bones, spinal length almost always normal. Features - short limbs, normal trunk, large head, saddle nose, exaggerated lumbar lordosis normal mental and sexual development, spinal problems. Homozygotes - neonatal death (Harrisons)

[Q: 532] OnExamination - Endocrinology

A 70-year-old woman is referred by a with a breast lump. She was asymptomatic but her investigations reveal:

Corrected calcium 2.72 mmol/L (2.2 - 2.6)

Phosphate 0.80 mmol/L (0.8-1.4)

Alkaline phosphatase 110 U/L (20 - 95)

PTH concentration 5.1 pmol/L (0.9-5.4)

What is the most likely diagnosis?

- 1- bony metastases
- 2- chronic vitamin D excess
- 3- ectopic PTH related peptide (PTHrp) secretion
- 4- multiple myeloma
- 5- primary hyperparathyroidism

Answer & Comments

Answer: 5- primary hyperparathyroidism

This patient has hypercalcaemia with a lowish phosphate concentration but an inappropriately normal PTH concentration suggesting hyperparathyroidism which is a relatively common disorder amongst elderly females. The story of the breast lump in this case is endeavouring to throw the candidate. Vitamin D excess would be expected to cause an elevated Phosphate.

[Q: 533] OnExamination -
Endocrinology

Which of the following is true concerning a 68-year-old male with type 2 diabetes diagnosed with type IV renal tubal acidosis?

- 1- Aminoaciduria would be expected.
- 2- Fludrocortisone treatment is effective
- 3- Increased Glomerular filtration rate is expected.
- 4- Increased urinary bicarbonate would be expected.
- 5- Normal renal handling of K⁺ and H⁺

Answer & Comments

Answer: 2- Fludrocortisone treatment is effective

H⁺ secretion, sodium reabsorption and ammonia production diminishes. RTA 4 is in effect hyporeninaemic hypoaldosteronism or failure of aldosterone action and thus helped treated with mineralocorticoids. It is usually seen in chronic renal disease and hence low GFR and particularly. Aminoaciduria and increased urine bicarbonate are features of RTA types 1 and 2.

[Q: 534] OnExamination -
Endocrinology

Adult growth hormone deficiency is confirmed by:

- 1- A low IGF-1 concentration
- 2- An undetectable random Growth hormone concentration.
- 3- Suppression of GH below 2 mU/l (1.3 microg/l) with an oral glucose tolerance test
- 4- A peak growth hormone concentration of 6 mU/l (2 microg/l) with insulin induced hypoglycaemia
- 5- A low IGF binding protein-3 (IGFBP3) concentration

Answer & Comments

Answer: 4- A peak growth hormone concentration of 6 mU/l (2 microg/l) with insulin induced hypoglycaemia

The diagnosis of adult GHD depends on a peak GH response of less than 9 mU/l to insulin induced hypoglycaemia.

[Q: 535] OnExamination -
Endocrinology

Which of the following concerning Diabetic retinopathy is correct?

- 1- Is unusual in type 2 diabetic patients
- 2- Improved glycaemic control is more effective than hypertensive control in reducing progression of disease.
- 3- Normal visual acuity is seen in Proliferative retinopathy.
- 4- Progression may be reduced statin therapy
- 5- Soft exudates are a feature of background retinopathy.

Answer & Comments

Answer: 3- Normal visual acuity is seen in Proliferative retinopathy.

Diabetic retinopathy occurs in both type 1 and 2 DM and may be a presenting feature in Type2 as the condition may have existed for many years prior to diagnosis. Progression may be slowed with improved glycaemic and hypertensive control but the latter has been shown to be more effective at reducing progression (UKPDS). There are no data at present to suggest that Statin therapy reduces disease progression. Soft exudates are a feature of pre-proliferative Rn and despite quite marked new vessel disease the visual acuity may be normal.

[Q: 536] OnExamination -
Endocrinology

A 65-year-old male undergoes a CT headscan

after falling from a ladder and knocking himself out. The CT report reveals that he has a 1.3 cm macroadenoma which does not encroach upon the optic chiasm. On recovery he is perfectly well and examination is entirely normal, including full visual fields to confrontation.

Investigations reveal normal thyroid function, testosterone concentration and short synacthen test results. His prolactin concentration is 550 $\mu\text{U/L}$ (NR 50-450).

What is the most appropriate treatment for this patient?

- 1- Advise trans-sphenoidal hypophysectomy
- 2- Arrange pituitary radiotherapy
- 3- Arrange serial imaging
- 4- No further investigation/treatment required
- 5- Treat with Cabergoline

Answer & Comments

Answer: 3- Arrange serial imaging

This man has a co-incidentally detected pituitary macroadenoma. The small elevation in prolactin probably reflects stalk compression and does not indicate that this is a prolactinoma. In macroprolactinomas, the prolactin concentration is greater than 2000 $\mu\text{U/L}$. In this man's case, with no visual field defects and the tumour being distant from the chiasm, the most appropriate treatment would be observation with serial scanning to assess for any change in size that would then merit surgical intervention. However, this man who is eupituitary may never encounter any growth in this co-incidentally detected non-functional pituitary tumour.

[Q: 537] OnExamination - Endocrinology

A 30-year-old female who is 24 weeks pregnant presents with a blood pressure on

three separate occasions of approximately 160/110 mmHg. Her liver function tests show:

Aspartate transaminase 150 U/L (5-45)

Alkaline Phosphatase 213 U/L (50-120)

Bilirubin 31 $\mu\text{mol/L}$ (0-18)

Which antihypertensive is indicated?

- 1- Atenolol
- 2- Irbesartan
- 3- Labetalol
- 4- Methyldopa
- 5- Ramipril

Answer & Comments

Answer: 3- Labetalol

ACEIs are contraindicated in pregnancy, as they cause renal dysgenesis in the foetus. For this reason A2RBs are also not recommended for use in pregnancy. There is a theoretical risk of IUGR with the use of atenolol in pregnancy, although the studies which showed this effect were done with very large doses of atenolol. One would not utilise Methyldopa in a patient with abnormal LFTs.

[Q: 538] OnExamination - Endocrinology

A 73-year-old woman presented with thirst and polyuria of six months duration. She had suffered several episodes of lower back pain. She was on no medication. On examination she looked well, had a dorsal kyphosis and a blood pressure of 170/95 mmHg.

Investigations revealed:

erythrocyte sedimentation rate 15 mm/1st hour (0-30)

serum urea 11.9 mmol/L (2.5-7.5)

serum creatinine 175 $\mu\text{mol/L}$ (60-110)

serum albumin 40 g/L (37-49)

serum total calcium 2.98 mmol/L (2.2-2.6)

What is the most likely cause of this lady's hypercalcaemia?

- 1- Metastatic breast cancer
- 2- Myeloma
- 3- Osteoporosis
- 4- Primary hyperparathyroidism
- 5- Sarcoidosis

Answer & Comments

Answer: 4- Primary hyperparathyroidism

The prevalence of hyperparathyroidism is said to be 4 per 1000 in women over 60, and is 2-3 times more common in women than men. The lower back pain may be loin pain due to renal colic caused by renal calculi or due to osteoporosis. The renal impairment may be associated with renal calculi, perhaps due to calculi-induced hydronephrosis in extreme cases. Renal impairment in hyperparathyroidism is not uncommon. Chronic hypercalcaemia can compromise the renal concentrating ability, leading to polydipsia and polyuria.

The kyphosis may be due to osteoporosis, which is commonly seen in conjunction with hyperparathyroidism. Classically, hypertension has been associated with hyperparathyroidism. Associated with myeloma one would expect a drop in albumin concentration together with a markedly elevated ESR.

[Q: 539] OnExamination - Endocrinology

Which of the following is a cause of the syndrome of inappropriate ADH secretion:

- 1- Bumetanide
- 2- Fluoxetine
- 3- Dexamethasone
- 4- Carbenoxolone
- 5- Lithium

Answer & Comments

Answer: 2- Fluoxetine

SSRIs are a recognised cause of SIADH. Bumetanide would cause excess renal Na losses. Carbenoxolone would cause apparent mineralocorticoid excess with hypokalaemia and salt retention as would dexamethasone. Lithium causes diabetes insipidus.

[Q: 540] OnExamination - Endocrinology

The peroxisome proliferator activated receptor gamma (PPAR gamma)

- 1- Is a G-protein coupled receptor
- 2- Is activated by free fatty acid as the endogenous ligand
- 3- Is antagonised by thiazolidinediones
- 4- Is a member of the Cytokine receptor superfamily
- 5- Is antagonised by Low density Lipoprotein (LDL).

Answer & Comments

Answer: 2- Is activated by free fatty acid as the endogenous ligand

PPAR gamma is an intra-cellular receptor that is activated by free fatty acids (which are the natural endogenous ligands) and the Thiazolidinediones such as Rosiglitazone and Pioglitazone. On ligand binding it associates with the Retinoid X receptor and couples with DNA producing downstream gene activation with protein synthesis that controls adipocyte differentiation and function, and is also related to cellular anti-inflammatory effects.

[Q: 541] OnExamination - Endocrinology

A 19-year-old female is concerned following exposure to meningococcal meningitis. Her flatmate contracted meningococcal meningitis and she now wants preventative treatment.

She is generally well without any past medical history. She takes Logynon as a contraceptive agent and uses a salbutamol inhaler infrequently.

Which prophylactic anti-microbial treatment would you select?

- 1- Clarithromycin
- 2- Ciprofloxacin
- 3- Augmentin
- 4- Doxycycline
- 5- Rifampicin

Answer & Comments

Answer: 2- Ciprofloxacin

Rifampicin is a reasonable choice as prophylaxis against meningococcal infection but in this 19-year-old sexually active student may be expected to reduce the efficacy of the oral contraceptive through liver enzyme induction. Therefore Ciproxin would be the most appropriate agent from the above list as it does not induce Cytochrome p450.

[Q: 542] OnExamination - Endocrinology

A 60-year-old patient with metastatic breast carcinoma for attends the clinic. She complains of pain in the jaw and ulceration within the oral cavity, which has persisted for 4 weeks following a dental extraction. She has had a course of antibiotic therapy for suspected secondary infection of the ulceration. On examination there is ulceration within the oral cavity, which extends as far as the underlying mandible.

Which of the following drugs is likely to be responsible for her presentation?

- 1- Anastrozole
- 2- Diclofenac.
- 3- Prednisolone
- 4- Tamoxifen

5- Zoledronic acid

Answer & Comments

Answer: 5- Zoledronic acid

The likely causative agent is the nitrogen containing bisphosphonate Zoledronic acid. The clinical scenario suggests a diagnosis of Bisphosphonate associated osteonecrosis of the jaw. This is a recently recognised adverse effect of bisphosphonate therapy. This is a consequence of potent antiresorptive action of the nitrogen containing bisphosphonates. Most cases have been associated with Zoledronic acid and Pamidronate given Intravenously for metastatic bone disease. The reported incidence in patients with malignancy treated with these drugs is between 1.3-4.0%. Dental disease is a recognised predisposing factor. The lesions usually heal with minimal surgical debridement, chlorhexidine mouthwashes, antibiotics and analgesia.

[Q: 543] OnExamination - Endocrinology

Which of the following is a feature of pseudohypoparathyroidism?

- 1- Increased urinary phosphate and cAMP with PTH infusion
- 2- Low serum PTH
- 3- Low serum calcium and low serum phosphate
- 4- Low serum calcium and high serum phosphate
- 5- Shortened 2nd and 3rd metacarpals

Answer & Comments

Answer: 4- Low serum calcium and high serum phosphate

The biochemistry shows a hypocalcaemia with hyperphosphataemia being usual but elevated PTH due to resistance to parathormone (PTH).

This is due to mutation of the PTH receptor with abnormality of the G α subunit with reduced cAMP production following a PTH infusion. There are associated phenotypic signs including short stature, low IQ and shortened 4th and 5th metacarpals.

[Q: 544] OnExamination - Endocrinology

A 22-year-old woman presented with a 5-year history of hirsutism with her having noticed coarse dark hair under her chins. Being a teacher in a primary school, these symptoms are very distressing for her. She has tried local measures such as shaving and applying depilatory creams but without lasting success. Her periods are irregular with oligomenorrhea. She attained menarche at the age of 14-years. She has not yet conceived and has had a coil fitted for contraception. She takes 5mg diazepam at night. On examination, she had a BMI of 24. She had coarse, dark hair over her chin, lower back and inner thighs. She does not have galactorrhea to expression and there were no other clinical features to suggest cushings.

Investigations during the follicular phase:

serum androstenedione 10.1 nmol/L (0.6-8.8)

serum dehydroepiandrosterone sulphate 11.6 μ mol/L (3-12)

serum 17-hydroxyprogesterone 18.6 nmol/L (1-10)

serum oestradiol 380 pmol/L (200-400)

serum testosterone 2.6 nmol/L (0.5-3)

plasma luteinising hormone 3.3 U/L (2.5-10)

plasma follicle-stimulating hormone 3.6 U/L (2.5-10)

What is the next most appropriate investigation?

- 1- 24 hour urinary free cortisol
- 2- CT scan of adrenals
- 3- GnRH test

- 4- short synacthen test with 17 hydroxy progesterone
- 5- ultrasound scan of ovaries

Answer & Comments

Answer: 4- short synacthen test with 17 hydroxy progesterone

In this case the patient has features that would suggest PCOS yet the 17OHP concentration is elevated and is compatible with non classical CAH yet just below the threshold off 33 to confidently make the diagnosis. Thus a short synacthen test would be the most appropriate investigation with measurement of 17OHP. A rise in 17OHP above 33 nmol/l suggests non-classical CAH.

[Q: 545] OnExamination - Endocrinology

Which of the following hormones acts through cyclic AMP as the second messenger?

- 1- insulin
- 2- Oestradiol
- 3- PTH
- 4- TRH
- 5- tri-iodothyronine

Answer & Comments

Answer: 3- PTH

Unlike steroids (progesterone, testosterone, oestradiol and cortisol) other ionic hormones such as Adrenaline, GHRH, glucagon, LH, FSH, PTH, and TSH are unable to pass the plasma membrane acting upon cell surface receptors and then through cAMP as the second messenger. Insulin acts through MAP kinase pathway, as does GH and Prolactin. TRH, GnRH and ADH act through calcium/Phosphoinositide. Nitric oxide and ANP act through cGMP. T3 acts by binding to intracellular receptors.

[Q: 546] OnExamination -
Endocrinology

A 42-year-old male presents with tiredness and central weight gain, two years after having undergone pituitary surgery for a non-functional pituitary tumour. He has otherwise recovered from his pituitary surgery well, has been found to have complete anterior hypopituitarism and is receiving stable replacement therapy with testosterone monthly injections, thyroxine and hydrocortisone.

On examination there are no specific abnormalities, his vision is 6/9 in both eyes and he has no visual field defects. From his notes you see that he has gained 8kg in weight over the last six months and his BMI is 31 kg/m². His blood pressure is 122/72 mmHg. Thyroid function tests and testosterone concentrations have been normal. A post-operative MRI scan report shows that the pituitary tumour has been adequately cleared with no residual tissue.

Which of the following is the likely cause of his current symptoms?

- 1- Aldosterone deficiency
- 2- Depression
- 3- DDAVP deficiency
- 4- Growth hormone deficiency
- 5- Somatisation disorder

Answer & Comments

Answer: 4- Growth hormone deficiency

This young patient presents with deteriorating tiredness and weight gain after having had pituitary surgery for a non-functioning pituitary tumour. He has associated anterior hypopituitarism but is receiving appropriate and stable replacement therapy. However, these symptoms are typical of an untreated adult growth hormone deficiency and reductions in quality of life, reduced energy and detrimental changes in body composition

are well recognised. Recent evidence would suggest that GH replacement therapy in addition to his current replacement therapy does improve symptoms and quality of life and is endorsed by NICE guidance.

The renin-aldosterone system is independent of the hypothalamo-pituitary axis and therefore aldosterone is not necessary. The patient does not have any symptoms of thirst or polyuria and therefore vasopressin deficiency is also an unlikely cause of his problems. Whilst depression or somatisation are possibilities it is important to recognise that the symptoms of tiredness and the weight gain is more in keeping with GH deficiency and no other features of either of the former diagnoses are suggested.

[Q: 547] OnExamination -
Endocrinology

Which of the following is true of IGF-1 concentrations

- 1- Concentrations are reduced in pregnancy
- 2- Concentrations are elevated in hepatic cirrhosis
- 3- Concentrations are usually elevated in adult growth hormone deficiency
- 4- Concentrations are reduced in starvation
- 5- Concentrations are elevated in diabetes mellitus

Answer & Comments

Answer: 4- Concentrations are reduced in starvation

IGF-1 concentrations are often increased in pregnancy. Reduced IGF-1 is typically found in adult GHD, Cirrhosis of the liver due to reduced synthesis, diabetes mellitus and starvation.

[Q: 548] OnExamination -
Endocrinology

A 50-year-old man presents with a diagnosis of acromegaly but has normal visual fields.

Which of the following is the most appropriate treatment for this patient?

- 1- Bromocriptine
- 2- Cabergoline
- 3- Radiotherapy
- 4- Somatostatin analogue therapy
- 5- Trans-sphenoidal hypophysectomy

Answer & Comments

Answer: 5- Trans-sphenoidal hypophysectomy

The most appropriate treatment for acromegaly in this middle-aged man which may prove curative is surgery. Somatostatin therapy, although frequently effective in reducing GH, would not be advocated in this young patient who would require lifelong therapy.

[Q: 549] OnExamination -
Endocrinology

A 39-year-old female presents with polyuria and is passing 4 litres of urine per day. She was recently started on a new medication

Serum sodium 128 mmol/l

Plasma osmolality 272 mosmol/l (275-290)

Urine osmolality 380 mosmol/l (350-1000)

Which of the following drugs was prescribed?

- 1- Aspirin
- 2- Fluoxetine
- 3- Furosemide
- 4- Lithium
- 5- Metoprolol

Answer & Comments

Answer: 2- Fluoxetine

This lady has hyponatraemia, hypotonicity (low serum osmolality) and inappropriately concentrated urine which is consistent with Syndrome of Inappropriate ADH. Of the drugs listed fluoxetine is the most likely cause of SIADH.

[Q: 550] OnExamination -
Endocrinology

With which of the following is hyperprolactinaemia associated?

- 1- Cabergoline therapy
- 2- Depression
- 3- Fluoxetine therapy
- 4- Hyperthyroidism
- 5- Sheehan's syndrome

Answer & Comments

Answer: 3- Fluoxetine therapy

Hyperprolactinaemia may be manifest by a milky discharge from the breasts. Causes include, prolactinoma, hypothyroidism (far increased TRH), Non-functional tumour with stalk compression and drugs in particular dopamine antagonists such as chlorpromazine, haloperidol and domperidone. Pregnancy is a particularly common cause of hyperprolactinaemia. Other drugs that are occasionally reported include SSRIs. PCOs is often associated with idiopathic hyperprolactinaemia.

[Q: 551] OnExamination -
Endocrinology

A 19-year-old male presents with concerns regarding his pubertal development. On examination he is 1.8 m tall, thin and has little pubic and axillary hair. Both testes are approximately 5 mls in volume (Normal 15mls). No other abnormalities are encountered. Investigations reveal: LH 3.3 mu/l (3-10) FSH 5.5 mu/l (3-10) Testosterone 5.5 nmol/l (9-30)

Which of the following is the most likely diagnosis?

- 1- Anorexia nervosa
- 2- Craniopharyngioma
- 3- Kallmann syndrome
- 4- Klinefelter's syndrome
- 5- Primary testicular failure

Answer & Comments

Answer: 3- Kallmann syndrome

This young male has delayed puberty with hypogonadotrophic hypogonadism. The most likely explanation would be Kallmann syndrome. Klinefelter's would be associated with elevated LH/FSH as would primary testicular failure. His height of 1.8m suggesting that he is tall would argue against this being anorexia despite his 'thin' appearance as if anorexia had preceded puberty then his stature should also have been affected. The only other possibility is Craniopharyngioma but this is probably less likely in an otherwise well man and other possible features should be included to suggest this diagnosis - visual fields maybe. You may wish to cry foul at this point and say that anosmia should be given as a clue to Kallmann's. However, in theory how often do you ask about sense of smell let alone test for it!

[Q: 552] OnExamination - Endocrinology

Which of the following statements regarding bariatric surgery is correct?

- 1- Bariatric surgery is contraindicated in adolescents
- 2- Is indicated in patients with a BMI <35 kg/m²
- 3- Is associated with a significant post-operative mortality
- 4- Is associated with nutritional deficiencies

- 5- Reduces cardiovascular mortality

Answer & Comments

Answer: 4- Is associated with nutritional deficiencies

Bariatric surgery is a major gastrointestinal procedure. Bariatric surgery in adolescents raises social, psychological and developmental issues, but adolescents are not excluded from surgery, and some hospitals have specialised programmes for younger patients. Potential candidates for surgery are those with a body mass index (BMI) exceeding 40, or BMI > 35 with serious co-morbidities (eg sleep apnoea, type 2 diabetes). Post-operative mortality ranges from 0.1 to 2%.

Vomiting is a risk associated with bariatric surgery, as is dumping syndrome and nutritional deficiencies. There is no evidence as yet, that bariatric surgery reduces cardiovascular mortality in patients.

[Q: 553] OnExamination - Endocrinology

An 18-year-old woman presented with a history of 15 kg weight loss in the previous four months. She has been amenorrhoeic for some months. On examination she had fine lanugo hair and a blood pressure of 110/60 mmHg.

Which one of the following laboratory results would support the most likely clinical diagnosis?

- 1- High plasma follicle stimulating hormone concentration
- 2- Low plasma testosterone concentration
- 3- High serum ferritin concentration
- 4- Normal plasma cortisol concentration
- 5- Suppressed thyroid stimulating hormone concentration

Answer & Comments

Answer: 4- Normal plasma cortisol concentration

The question alludes to a patient with Anorexia nervosa. Anorexia is associated with functional hypogonadotrophic hypogonadism with low FSH and LH levels. Cortisol levels may be increased but are typically within the 'normal range'. They may however, may fail to suppress with dexamethasone. Plasma testosterone levels are normal in females with anorexia. Basal levels of TSH, as well as T4 and T3 are normal. Ferritin levels are low in a state of malnutrition.

[Q: 554] OnExamination - Endocrinology

A 16-year-old girl is diagnosed with Turner's syndrome.

Which of the following autoimmune conditions is most commonly associated with Turner's?

- 1- Addison's disease
- 2- Autoimmune hepatitis
- 3- Hashimoto's thyroiditis
- 4- Sjogren's syndrome
- 5- Vitamin B₁₂ deficiency

Answer & Comments

Answer: 3- Hashimoto's thyroiditis

Hypothyroidism is quite common occurring in up to 24% of patients with Turner's syndrome. It is typically autoimmune in origin - Hashimoto's thyroiditis though the exact explanation for its high prevalence is not known.

[Q: 555] OnExamination - Endocrinology

A 48-year-old lady has obesity with a BMI of 37 kg/m² and her waist measurement is 115 cm (very high). She gained most of the weight

about 10 years ago and since that time she has tried many different forms of diet and weight-loss clubs. Although she enjoys swimming she is finding it harder to keep up her exercise and walking is restricted to a few hundred metres because of foot pain.

On further questioning her diet is quite reasonable consisting of about 1800 KCal per day. She eats breakfast, bases her meals on starchy foods, eats plenty of fibre and at least five portions of vegetables or fruit per day.

Which of the following management strategies according to NICE guidance on obesity (published December 2006) would be advisable for this lady?

- 1- Diet and physical activity, consider drugs
- 2- Extended period, very low calorie diet
- 3- General advice on healthy weight and lifestyle
- 4- Referral for bariatric surgery
- 5- Referral to specialist obesity service

Answer & Comments

Answer: 1- Diet and physical activity, consider drugs

NICE recommendations are to first classify the level of this lady's obesity. This can easily be achieved by looking at the tables in the NICE quick-reference guide on obesity.

Classification BMI kg/m²

Healthy weight 18.5 - 24.9

Overweight 25 - 29.9

Obesity I 30 - 34.9

Obesity II 35 - 39.9

Obesity III 40 or more

Her waist circumference is very high (> 88 cm) and, in the absence of co-morbidities, we can see that the initial management should be diet and exercise with consideration of drug treatment which should be discussed.

Extended period (longer than 12 weeks) low-calorie diet and bariatric surgery may be considered but would warrant specialist referral.

[Q: 556] OnExamination - Endocrinology

A 17-year-old female attends clinic complaining of hirsutism and oligomenorrhoea.

Which of the following would be most suggestive of a diagnosis of Polycystic Ovarian Syndrome?

- 1- Increased androstenedione concentration
- 2- Increased insulin concentration
- 3- Increased Prolactin concentration
- 4- Increased FSH concentration
- 5- Increased Sex Hormone binding globulin (SHBG) concentration

Answer & Comments

Answer: 1- Increased androstenedione concentration

PCOs is associated with a raised LH:FSH ratio, with insulin resistance and hyperandrogenism as evidenced by raised androstenedione and slightly raised testosterone. Elevated prolactin concentrations although a feature of PCOs is not specific of the diagnosis and may suggest microprolactinoma. Although insulin resistance is a feature of PCOs, a raised insulin concentration is rather irrelevant and no one would measure this in clinical practice. It is often elevated in association with testosterone secreting tumours.

[Q: 557] OnExamination - Endocrinology

Which of the following cell types are linked with the substance they synthesize ?

- 1- Gastric chief cells - Intrinsic factor
- 2- Islet A cells - somatostatin

- 3- Islet B cells - amylin
- 4- Islet D cells - pancreatic polypeptide
- 5- Islet F cells - glucagon

Answer & Comments

Answer: 3- Islet B cells - amylin

Islet beta cells produce insulin and Amylin, as well as C-peptide, pro-insulin and GABA. Islet D cells produce somatostatin, F cells produce pancreatic polypeptide and A cells produce glucagon. Gastric chief cells produce pepsinogen whilst gastric parietal cells produce acid and intrinsic factor.

[Q: 558] OnExamination - Endocrinology

A 52-year-old female presents with tiredness. There are no specific abnormalities noted on examination, but investigations reveal a T4 of 21.1 (NR 9.8 - 23), a T3 of 5.2 pmol/l (NR 3.3 - 5.5) and a TSH of 0.05 mU/l (NR 0.1 - 5 mU/l). Thyroid autoantibody titres are all undetectable.

These results suggest a diagnosis of

- 1- DeQuervain's thyroiditis
- 2- Sick euthyroid syndrome
- 3- Solitary toxic nodule
- 4- Graves' disease
- 5- Hashimoto's thyroiditis

Answer & Comments

Answer: 3- Solitary toxic nodule

This patient has subclinical hyperthyroidism and, in the absence of thyroid auto-antibodies, the most probable explanation of these thyroid function abnormalities is a solitary toxic nodule.

[Q: 559] OnExamination -
Endocrinology

Which of the following suggests a diagnosis of familial combined hyperlipidaemia (FCHL) rather than heterozygous familial hypercholesterolaemia (FH)?

- 1- Tendon xanthomas
- 2- Presence of glucose intolerance
- 3- Strong family history of premature coronary artery disease
- 4- Presence of arcus senilis
- 5- Absence of hyperuricaemia

Answer & Comments

Answer: 2- Presence of glucose intolerance

The genetic dyslipidaemias occur in one third of patients who have suffered from their first myocardial infarction below the age of 50 years in men. The commonest is familial combined hyperlipidaemia (two thirds), with a fifth due to familial hypercholesterolaemia. The former can be diagnosed only on family studies, and there is elevation of fasting plasma triglycerides not associated with hypercylomicronaemia. It is autosomal dominant, and some family members may have hypercylomicronaemia. Only 20% of children have elevated triglycerides before the age of 25. Obesity, insulin resistance, hyperinsulinaemia, glucose intolerance, and hyperuricaemia are associated. Heterozygous familial hypercholesterolaemia is dominantly inherited, and results from defects in the LDL receptor. The most important clinical manifestation is premature coronary artery disease, particularly with onset between the third or fourth decade. Tendon xanthomata and arcus cornea are rarely present in children, but are very important signs to identify.

[Q: 560] OnExamination -
Endocrinology

An 80 year-old male presents with a brief history of weakness and giddiness, following an episode of diarrhoea. He has been taking bendroflumethiazide for the last 3 years. On examination, his pulse is 100 beats per minute with a blood pressure of 130/80 mmHg (lying) and 100/70 mmHg (standing). Investigations reveal:

Sodium 120 mmol/L

Potassium 5.5 mmol/L

Urea 13 mmol/L

Creatinine 130 umol/L

random plasma glucose 13 mmol/L

What is the most likely cause of the hyponatraemia?

- 1- Bendroflumethiazide
- 2- Diarrhoea
- 3- Hyperglycaemia
- 4- Inappropriate secretion of antidiuretic hormone
- 5- Renal tubular acidosis

Answer & Comments

Answer: 5- Renal tubular acidosis

The patient is diabetic as reflected by the elevated random glucose, has hyponatraemia, renal impairment and mild hyperkalaemia which appears to have been precipitated following diarrhoea. Hypoadrenalism is unlikely as he has hyperglycaemia and the hyperglycaemia would itself be expected to cause a dehydration and hence hypernatraemia. This sort of picture in an elderly male diabetic is typical of hyporeninaemic hypoaldosteronism - type IV RTA and could be exacerbated both by the diarrhoea and by the diuretic. It is unlikely that the diarrhoea alone has caused the hyponatraemia.

[Q: 561] OnExamination -
Endocrinology

A type 2 diabetic patient being treated with gliclazide, presents with sweating and dizziness. He is on treatment for hypertension, atrial fibrillation, joint pain and indigestion. Blood glucose was 1.9 mmol/L.

Which of the following drugs is responsible?

- 1- Aspirin
- 2- Atenolol
- 3- Digoxin
- 4- Fluconazole
- 5- Ranitidine

Answer & Comments

Answer: 1- Aspirin

Gliclazide is highly bound to plasma proteins, about 94%. Its free plasma level increases on displacement by aspirin given for joint pains. As a result of drug interaction, hypoglycemia may be potentiated when a sulfonylurea is used concurrently with agents such as: long-acting sulfonamides, tuberculostatics, phenylbutazone, clofibrate, MAO inhibitors, coumarin derivatives, salicylates, probenecid, propranolol, cimetidine, disopyramide and angiotensin converting enzyme inhibitors. Plasma protein binding of fluconazole is low and it's excreted by kidney.

[Q: 562] OnExamination -
Endocrinology

A 40-year-old man was found to have acromegaly.

What is the most likely cause of death if treatment is unsuccessful?

- 1- Colorectal carcinoma
- 2- Diabetic nephropathy
- 3- Gastric carcinoma
- 4- Left ventricular failure
- 5- Increased intracranial pressure

Answer & Comments

Answer: 4- Left ventricular failure

If treatment of acromegaly is unsuccessful, the death rate from cardiovascular, cerebrovascular, respiratory and malignant disease is 2-4 times that of the general population. Classically the malignancy associated with acromegaly is tumour of the large intestine. Mortality is typically due to a cardiovascular cause if the condition is untreated. Thus heart failure is probably more common a cause of death than colonic neoplasia.

[Q: 563] OnExamination -
Endocrinology

Which one of the following is a feature of the VIPoma syndrome?

- 1- Alkalosis
- 2- Hypoglycaemia
- 3- Hypokalaemia
- 4- Increased gastric acid secretion
- 5- Provocation of VIP release by somatostatin

Answer & Comments

Answer: 3- Hypokalaemia

a, b,d,e: All opposite to what is expected. VIPOMA -Features vasoactive intestinal polypeptide secreting tumour, mainly pancreas rarely ganglioneuroblastoma (sympathetic chain or adrenal cortex), secretory diarrhoea ('pancreatic cholera'), weight loss, dehydration, abdominal colic, cutaneous flushing, raised plasma VIP, urea+Calcium, raised plasma pancreatic polypeptide, hypokalaemic acidosis (loss of alkaline secretions), achlorhydria, mildly raised glucose, normal functions of VIP. -increased intestinal secretion water and electrolytes - peripheral vasodilation -inhibits gastric acid secretion -potentiates acetylcholine action on salivary glands

[Q: 564] OnExamination -
Endocrinology

A 39-year-old male presents with gynaecomastia.

Which of the following is the most likely cause of his gynaecomastia?

- 1- Congenital adrenal hyperplasia
- 2- Prolactinoma
- 3- Hypopituitarism
- 4- Hypothyroidism
- 5- Seminoma

Answer & Comments

Answer: 5- Seminoma

Gynaecomastia is due to a perturbation in the testosterone to oestradiol ratio. Neither hyperprolactinaemia nor hypopituitarism disturb this ratio and are rarely associated with gynaecomastia. Unlike hyperthyroidism, hypothyroidism is not a cause. CAH is not a cause. However, gynaecomastia may be a presenting symptom of a seminoma and may arise due to HCG secretion.

[Q: 565] OnExamination -
Endocrinology

A 32-year-old woman presented with a six week history of 7kg weight loss and heat intolerance. Investigations revealed:

Free T₄ 45 pmol/L (10-22)

TSH <0.05 mU/L (0.5-5)

Which of the following features would support a diagnosis of Graves' disease?

- 1- Family history of Radio-iodine treatment
- 2- Lid lag
- 3- Multinodular goitre
- 4- Pretibial myxoedema
- 5- Unilateral exophthalmos

Answer & Comments

Answer: 4- Pretibial myxoedema

A tough question. The specific features that would support a diagnosis of Graves would include exophthalmos, thyroid bruit and pretibial myxoedema. The latter is pathognomonic, as exophthalmos may be a feature (rarely) of hashitoxicosis.

[Q: 566] OnExamination -
Endocrinology

Oral therapy with which of the following may cause galactorrhoea?

- 1- Bromocriptine
- 2- Cabergoline
- 3- Spironolactone
- 4- Cimetidine
- 5- Domperidone

Answer & Comments

Answer: 5- Domperidone

Domperidone is a dopamine antagonist producing large rises in prolactin concentrations. Spironolactone has no effect on prolactin and Cimetidine produces hyperprolactinaemia only when given IV. Both bromocriptine and cabergoline are dopamine agonists and reduce prolactin.

[Q: 567] OnExamination -
Endocrinology

A 36-year-old male presents with lethargy. He takes no medication and has generally been otherwise well. Examination reveals that he is obese with a BMI of 36.4 kg/m² and a blood pressure of 120/72. There are no abnormalities of the cardiovascular, respiratory or abdominal systems. Investigations reveal a sodium of 141 mmol/l, a potassium of 2.8 mmol/l, a urea of 5.6 mmol/l and a creatinine of 76 mmol/l.

What is the most likely diagnosis.

- 1- Conn's syndrome
- 2- Apparent mineralocorticoid excess
- 3- Cushing's syndrome
- 4- Hypokalaemic periodic paralysis
- 5- Bartter's syndrome

Answer & Comments

Answer: 5- Bartter's syndrome

Bartter's syndrome is a mixed bag of disorders but most frequently characterised by an autosomal recessive condition consisting of juxta-glomerular cell hyperplasia and secondary hyperaldosteronism. A normal or low blood pressure is typical. It may present in childhood with weakness and failure to thrive but may present co-incidentally in adulthood.

[Q: 568] OnExamination - Endocrinology

A 33-year-old female presents with tiredness and lethargy. Five years previously she had undergone a frontal surgery for a craniopharyngioma following presentation with amenorrhoea and headache. Post-operatively she developed seizures and was treated with sodium valproate. She was demonstrated to be hypopituitary and receives hydrocortisone, thyroxine, oestrogen replacement therapy and desmopressin.

Which of the following investigations would you select to confirm a growth hormone deficiency.

- 1- IGF-1 concentration
- 2- Insulin tolerance test
- 3- Clonidine test
- 4- L-dopa test
- 5- GHRH/Arginine test

Answer & Comments

Answer: 5- GHRH/Arginine test

This patient is more than likely to be GH deficient which would explain the lethargy but this requires confirmation before initiating treatment. Although an insulin tolerance test is the gold standard for the diagnosis of GHD, it is contra-indicated due to the epilepsy. Therefore GHRH/arginine is regarded as a suitable alternative.

[Q: 569] OnExamination - Endocrinology

A 64-year-old male presents with difficulty in micturition. He is diagnosed with benign prostatic hyperplasia and elects to receive finasteride.

Production of which of the following hormones would be selectively inhibited?

- 1- Testosterone
- 2- Dihydroepiandrosterone sulphate (DHEAS)
- 3- Androstenedione
- 4- Dihydrotestosterone (DHT)
- 5- IGF-1

Answer & Comments

Answer: 4- Dihydrotestosterone (DHT)

Finasteride is a 5 alpha-reductase inhibitor and inhibits the conversion of testosterone to the active DHT.

[Q: 570] OnExamination - Endocrinology

A 37-year-old female presents with galactorrhoea. She has a history of dyspepsia for which she receives omeprazole. Examination reveals a BMI of 23.5 kg/m² and a small amount of galactorrhoea to expression. Investigations show a prolactin concentration of 850 mU/l (NR 50 - 500 mU/l), an oestradiol of 88 pmol/l (NR 130 - 500), a LH of 3.2 mU/l (NR 3.5 - 8) and a FSH of 2.8 mU/l (NR 3 - 8).

What disorder should be considered?

- 1- Addison's disease
- 2- Hyperthyroidism
- 3- MEN type 1
- 4- Drug-induced hyperprolactinaemia
- 5- Hypothyroidism

Answer & Comments

Answer: 3- MEN type 1

The presence of hyperprolactinaemia with hypogonadotrophic hypogonadism suggests a diagnosis of a microprolactinoma and in combination with the recurrent dyspepsia a diagnosis of MEN type 1 should be considered. The galactorrhoea is not due to cimetidine as this does not cause hyperprolactinaemia. Addison's disease does not cause hyperprolactinaemia and both hypothyroidism and hyperthyroidism would not fit this clinical scenario.

[Q: 571] OnExamination - Endocrinology

Which of the following is associated with a GH secreting pituitary tumour

- 1- Gs alpha subunit mutation
- 2- Pit-1 mutation
- 3- H-ras mutation
- 4- Rb 1 mutation
- 5- p53 mutation

Answer & Comments

Answer: 1- Gs alpha subunit mutation

A stimulatory mutation of the Gs protein alpha subunit has been noted in approximately 30% of GH secreting pituitary tumours.

[Q: 572] OnExamination - Endocrinology

Which of the following is not a recognised

association of acromegaly?

- 1- Pseudogout
- 2- Hypertension
- 3- Goitre
- 4- Elevated serum phosphate levels
- 5- Reduced serum prolactin levels

Answer & Comments

Answer: 5- Reduced serum prolactin levels

Pseudogout is seen in acromegaly, but not gout. Hypertension, heart failure and cardiomyopathy may occur. Goitre is seen in 20%, along with other soft tissue swelling. Phosphate levels are elevated but calcium levels are not significantly increased. 30% have elevated prolactin levels, a combination of a damaged pituitary stalk reducing the dopamine suppression signal, and reduced TSH levels leading to increased TRH, which stimulates prolactin secretion

[Q: 573] OnExamination - Endocrinology

Which of the following antibodies are typically found in auto-immune adrenalitis (Addison's disease)

- 1- Anti-rho antibody
- 2- Anti-peroxidase antibody
- 3- Anti-21hydroxylase antibody
- 4- Anti-nuclear antibody
- 5- Anti-tryptophan hydroxylase antibody

Answer & Comments

Answer: 3- Anti-21hydroxylase antibody

21 hydroxylase is the enzyme involved in the cholesterol steroid pathway and has been found to be present in approximately 80% of cases.

[Q: 574] OnExamination -
Endocrinology

In randomised clinical studies, post-menopausal hormone replacement therapy

- 1- Reduces cardiovascular mortality.
- 2- Causes regression of coronary plaques.
- 3- Increases plasma LDL concentrations.
- 4- Increases plasma triglycerides
- 5- Reduces the incidence of stroke

Answer & Comments

Answer: 4- Increases plasma triglycerides

In RCTs, HRT has not been shown to reduce CV mortality or the incidence of stroke (Heart Estrogen Replacement Study - HERS), nor does it cause regression of coronary plaques (Estrogen replacement and angiography study - ERA). In fact, HRT has been shown to have an increased CV morbidity in the WHI study. It does not produce a raised LDL, but may increase HDL concentrations. Similarly it frequently produces a rise in triglyceride concentrations.

[Q: 575] OnExamination -
Endocrinology

A chromophobe adenoma of the pituitary would be expected in which of the following

- 1- Cushing's disease
- 2- Acromegaly
- 3- Non-functioning pituitary tumour
- 4- TSH secreting tumour
- 5- Prolactinoma

Answer & Comments

Answer: 3- Non-functioning pituitary tumour

A chromophobe adenoma refers to no uptake of dye within the tumourous specimen. This occurs in the non-secretory/non-functioning pituitary tumours.

[Q: 576] OnExamination -
Endocrinology

A 35-year-old woman presents with episodic sweats associated with hunger. She was otherwise well, and had gained some weight recently. Investigations reveal normal urea and electrolytes, liver function tests and full blood count. An overnight fasting plasma glucose is 3.8 mmol/l (NR 3-6).

What is the most appropriate investigation for this patient?

- 1- 24 hour ECG recording
- 2- 72 hr fast
- 3- fasting insulin and C-peptide concentrations
- 4- MR scan of pancreas
- 5- Short synacthen test

Answer & Comments

Answer: 2- 72 hr fast

This patient presents with features suggestive of spontaneous hypoglycaemia often due to an insulinoma. She requires confirmation of the suspected diagnosis and this should be undertaken with a 72 hr fast. If the patient develops symptoms then a plasma glucose is measured and if low, insulin and c-peptide is then collected and the fast terminated. We have been provided with a fasting plasma glucose on this patient which is normal. Measuring insulin and c-peptides with this normal glucose would provide no meaningful information. First we have to see whether she actually becomes hypoglycaemic.

[Q: 577] OnExamination -
Endocrinology

A 35-year-old man presents with left loin pain and haematuria. He comments that he has had three episodes of similar symptoms in the past. On examination, he is afebrile and has mild pallor. Investigations show:

Sodium 140 mmol/L (135 -145)

Potassium 3.0 mmol/L (3.5 5)
 Chloride 115 mmol/L (95 105)
 Bicarbonate 12 mmol/L (22 30)
 Calcium 2.5 mmol/L (2.2 2.6)
 Urea 19 mmol/L (2.5 7.5)
 Urinalysis pH 6.5, protein 1+, RBC 1+, White cell count 1+

What is the most likely diagnosis?

- 1- Bartter's syndrome
- 2- Conn's syndrome
- 3- Renal tubular acidosis type 1
- 4- Renal tubular acidosis type 2
- 5- Renal tubular acidosis type 4

Answer & Comments

Answer: 3- Renal tubular acidosis type 1

The patient has metabolic acidosis with failure to appropriately acidify the urine, pointing to a diagnosis of renal tubular acidosis (RTA). Type 1 RTA is due to distal tubule defect to excrete hydrogen ions whereas type 2 RTA is associated with proximal tubule defect to reabsorb bicarbonate. Type 1 is associated with nephrocalcinosis. Both type 1 and 2 are associated with hypokalaemia whereas type 4 is characterized by hyperkalaemia. Bartters and Conns syndromes are causes of hypokalaemia and metabolic alkalosis.

[Q: 578] OnExamination - Endocrinology

A 18 year-old girl presents with anxiety and palpitations. Her mother had been treated for an overactive thyroid gland having received radioiodine and was now on Thyroxine replacement therapy. On examination she had a pulse of 104 bpm with a fine tremor and lid lag. There was no goitre palpable.

Investigations revealed:

serum Free T₄ 33 pmol/L (10-20)

plasma thyroid stimulating hormone (TSH) <0.05 (0.5-4.5)

serum antithyroid peroxidase (anti TPO) titre 40 IU/L (<50)

What is the most likely cause of her symptoms?

- 1- factitious thyrotoxicosis
- 2- familial hyperthyroglobulinaemia
- 3- Hashitoxicosis
- 4- Graves' disease
- 5- Riedel's thyroiditis

Answer & Comments

Answer: 4- Graves' disease

Although the lead-in might make you think that this patient could gain access to thyroxine and so a diagnosis of factitious hyperthyroidism is possible, in practice this is extremely unlikely. A strong family history of thyrotoxicosis is typical for Graves' disease and the absence of a goitre with the absence of TPO antibodies (found in 80% of Graves cases) again is compatible with a diagnosis of Graves.

[Q: 579] OnExamination - Endocrinology

A 52-year-old woman presents with tiredness and weight gain. She is confirmed to have autoimmune thyroiditis.

Which of the following tumours is she at increased risk of developing?

- 1- Anaplastic carcinoma of the thyroid
- 2- Follicular carcinoma of the thyroid
- 3- Medullary carcinoma of the thyroid
- 4- Papillary carcinoma of the thyroid
- 5- Thyroid lymphoma

Answer & Comments

Answer: 5- Thyroid lymphoma

There is a small but recognised risk of developing thyroid lymphoma associated with autoimmune thyroiditis (aka Hashimoto's disease or lymphocytic thyroiditis). The risk is small and would certainly not be screened for, nor should it in patients with autoimmune thyroid disease.

[Q: 580] OnExamination - Endocrinology

A 60 year-old male with diet controlled type 2 diabetes mellitus is commenced on metformin due to deteriorating glycaemic control.

Which of the following is true regarding metformin?

- 1- It often causes hypoglycaemia
- 2- It is safe in patients with renal impairment
- 3- It may cause metabolic alkalosis
- 4- It is contra-indicated in patients suffering a myocardial infarction
- 5- It does not require any functioning pancreatic islet cells for its action

Answer & Comments

Answer: 4- It is contra-indicated in patients suffering a myocardial infarction

Metformin is a biguanide which acts to improve insulin sensitivity through mechanisms that involve hepatic gluconeogenesis and improved muscle glucose utilization. Thus, some insulin must be produced for it to have an effect. It is associated with hypoglycaemia although this side effect is unusual. It is contra-indicated in subjects with renal failure, hepatic failure and heart failure due to the association with lactic acidosis. The BNF states that there should be a 6 week "cooling off" period post-MI before the commencement or recommencement of metformin.

[Q: 581] OnExamination - Endocrinology

A 22-year-old woman presented with hirsutism and oligomenorrhea for the last 5-years. She is an accountancy trainee and does not want to conceive at least for the next couple of years. She is very anxious about her irregular menses and is especially worried as her mother was diagnosed with uterine cancer recently. Examination is essentially normal apart from coarse dark hair being noticed under her chins and over her lower back.

Investigations during the follicular phase:

serum androstenedione 10.1 nmol/L (0.6-8.8)
 serum dehydroepiandrosterone sulphate 11.6 μmol/L (3-12)
 serum 17-hydroxyprogesterone 5.6 nmol/L (1-10)
 serum oestradiol 220 pmol/L (200-400)
 serum testosterone 3.6 nmol/L (0.5-3)
 serum sex hormone binding protein 32 nmol/L (40-137)
 plasma luteinising hormone 3.3 U/L (2.5-10)
 plasma follicle-stimulating hormone 3.6 U/L (2.5-10)

What is the most appropriate treatment?

- 1- combined OCP
- 2- finasteride
- 3- metformin
- 4- progesterone only pill
- 5- spironolactone

Answer & Comments

Answer: 1- combined OCP

This young woman has typical features of PCOS with supportive biochemistry - elevated androstenedione, normal oestradiol and 17OHP. She wants treatment of her hirsutism, does not want to fall pregnant and the most

appropriate therapy would be the combined OCP such as Dianette.

[Q: 582] OnExamination - Endocrinology

A 40-year-old female who has been prescribed thyroid replacement therapy has routine thyroid function tests. On examination she appeared clinically euthyroid with no abnormal findings. Her TFTs revealed:

TSH 3.2 mU/L (0.35 - 5.0)

Total T₄ 20 nmol/L (55 - 144)

Free T₄ 2.6 pmol/L (9 - 24)

Total T₃ 2.5 nmol/L (0.9 - 2.8)

Which one of the following statements is correct?

- 1- Her thyroid hormone replacement is adequate
- 2- Investigation of pituitary function is required
- 3- She has tertiary hypothyroidism
- 4- She has a thyroiditis
- 5- She has sick euthyroid syndrome

Answer & Comments

Answer: 1- Her thyroid hormone replacement is adequate

This question is extremely poorly presented as no one, except for the RCP, measures total thyroid hormone concentrations. However, this patient has normal TSH, low total T₄ with normal total T₃ and really low free T₄ which would suggest that she is taking T₃ as replacement therapy. This may explain why no fT₃ figures are provided. Consequently she is receiving adequate replacement as reflected by the normal TSH. She does not have sick euthyroidism as it states in the run in that these measurements were routine. Although TSH is normal and tT₄ and fT₄ low, secondary/tertiary hypothyroidism would not explain the plum normal total T₃

concentration. She may well have had a thyroiditis such as Hashimoto's to have given her the hypothyroidism originally but she is now on replacement therapy and the former would not explain her TFTs.

[Q: 583] OnExamination - Endocrinology

A 44-year-old female presents with features suggestive of Cushing's syndrome. Initial investigations reveal a 24 hr Urine free cortisol concentration of 350 nmol/day (NR <250).

Which is the most appropriate investigation of this patient's suspected Cushing's syndrome?

- 1- ACTH concentration
- 2- 9am and Midnight cortisol
- 3- High dose dexamethasone suppression test
- 4- Low dose dexamethasone suppression test
- 5- Short synacthen test

Answer & Comments

Answer: 4- Low dose dexamethasone suppression test

This patient is clinically suspected to have Cushing's syndrome with the diagnosis being supported by elevated urine free cortisol concentrations. However, the diagnosis of hypercortisolism needs to be established and the best way of doing this is with a low dose dexamethasone suppression test (DXM 0.5 mg qds for 2 days). The high dose test (2 mg qds for 2 days) adds little diagnostic value over and above the low dose test. 9am and Midnight cortisol concentrations would not add much to the suspicion of hypercortisolism which is provided by the urine free cortisol. Short synacthen tests are used to assess for hypoadrenalism. A CRF test is used occasionally to distinguish between ectopic and pituitary dependent Cushing's. ACTH concentrations would also be valuable after the diagnosis is confirmed to assess for ACTH dependency.

[Q: 584] OnExamination -
Endocrinology

Which of the following is associated with Congenital Adrenal Hyperplasia?

- 1- Delayed puberty
- 2- Hypopigmentation
- 3- Hyporeninaemia
- 4- Persistent Wolffian duct
- 5- Premature epiphyseal closure

Answer & Comments

Answer: 5- Premature epiphyseal closure

Premature epiphyseal closure is a classical feature of CAH, and is secondary to high levels of sex steroids. Under, and over treatment of CAH patients puts patients at risk of short stature, over treatment because of the glucocorticoid induced inhibition of the growth axis. CAH is associated with precocious puberty caused by long term exposure to androgens, which activate the hypothalamic-pituitary-gonadal axis.

Similarly, CAH is associated with hyperpigmentation, and hyperreninaemia due to sodium loss and hypovolaemia. The Wolffian duct is never formed in CAH.

[Q: 585] OnExamination -
Endocrinology

Which of the following is a characteristic feature of familial hypercholesterolaemia?

- 1- Autosomal dominant inheritance
- 2- elevated chylomicrons
- 3- hypertriglyceridaemia
- 4- increased expression of LDL receptors
- 5- Palmar xanthomas

Answer & Comments

Answer: 1- Autosomal dominant inheritance

Familial hypercholesterolaemia is an autosomal dominant condition manifest by increased LDL concentrations (not chylomicrons) due to constitutional abnormalities and reduced numbers of the LDL receptor. Hypertriglyceridaemia is not characteristic and HDL concentrations are usually decreased. Tendon xanthomata are characteristic and the condition is associated with a premature cardiovascular mortality.

[Q: 586] OnExamination -
Endocrinology

A 35-year-old female is found to have a solitary mass on the chest x-ray. Biopsy confirms this to be a carcinoid tumour of the lung.

Which of the following are likely to be associated with this lesion?

- 1- Cushing's syndrome
- 2- Hyponatraemia
- 3- Pellagra
- 4- Pulmonary hypertension
- 5- Carcinoid syndrome

Answer & Comments

Answer: 1- Cushing's syndrome

Carcinoid tumours of the foregut (such as lung) unlike tumours of the midgut are not associated with carcinoid syndrome but may secrete CRF/ACTH resulting in ectopic Cushing's syndrome. Other associated conditions where foregut carcinoid tumours are found in the pancreas are associated with Zollinger-Ellison syndrome and VIPoma. A bronchial carcinoid tumour has rarely been reported in association with Acromegaly (ectopic GHRH). They may also be found in association with MEN type 1 where pancreatic neuroendocrine tumours predominate.

[Q: 587] OnExamination -
Endocrinology

A 17 year-old girl presents with vomiting and her investigations show:

sodium 120 mmol/L (137 - 144)

potassium 3.0 mmol/L (3.5-4.9)

urea 2.2 mmol/L (2.5 - 7.5)

urine sodium 2 mmol/L

urine osmolality 700 mosmol/kg (350 - 1000)

What is the most likely diagnosis?

- 1- Addison's disease
- 2- bulimia nervosa
- 3- diuretic abuse
- 4- syndrome of inappropriate antidiuretic hormone secretion
- 5- water intoxication

Answer & Comments

Answer: 2- bulimia nervosa

This patient is likely to have Bulimia ?young girl with a likely low body mass contributing to the low urea, vomiting contributing to the hypokalaemia/hyponatraemia. Her urine sodium is appropriately low and due to a relative dehydration she has appropriately concentrated urine. This is not Addison's disease as urine sodium would be high with high urea and likely high potassium. Similarly it is not SIADH due to the low urine sodium. Diuretic abuse would cause high urine sodium. Water intoxication would produce a dilute urine.

[Q: 588] OnExamination -
Endocrinology

A 26-year-old man presented with polydipsia and polyuria for the last 2 years.

Investigations:

serum urea 8.4 mmol/L (2.5-7.5)

serum creatinine 108 µmol/L (60-110)

serum corrected calcium 2.82 mmol/L (2.2-2.6)

serum phosphate 0.73 mmol/L (0.8-1.4)

plasma parathyroid hormone 6.8 pmol/L (0.9-5.4)

Which of the following mechanisms is responsible for the hypophosphatemia observed?

- 1- increased deposition of calcium phosphate crystals in soft tissues
- 2- increased gastrointestinal secretion of phosphates
- 3- increased renal tubular secretion of phosphates
- 4- reduced gastrointestinal absorption of phosphates
- 5- reduced renal tubular reabsorption of phosphates

Answer & Comments

Answer: 5- reduced renal tubular reabsorption of phosphates

This young patient has mild hypercalcaemia, elevated PTH and low phosphate indicating primary hyperparathyroidism. The hypophosphataemia is due to the reduced renal reabsorption of phosphate.

[Q: 589] OnExamination -
Endocrinology

A 32-year-old woman treated with hydrocortisone 10 mg in the morning and 10 mg in the evening for Addison's disease, presents to the clinic with poor compliance. She feels that the hydrocortisone upsets her stomach and wants to switch to enteric coated Prednisolone.

What would be the appropriate corresponding daily dose of prednisolone?

- 1- 4mg daily
- 2- 5mg daily

- 3- 7mg daily
- 4- 10mg daily
- 5- 15mg daily

Answer & Comments

Answer: 2- 5mg daily

The approximate equivalent glucocorticoid action of prednisolone to Hydrocortisone is 4:1. Hence the equivalent dose for 20mg of Hydrocortisone is roughly 5mg per day of prednisolone.

[Q: 590] OnExamination - Endocrinology

A 34-year-old man presents with a six month history of tiredness, weight gain and cold intolerance. On examination he appeared hypothyroid and had a firm goitre. Investigations reveal:

Free T₄ 6 pmol/L (10-22)

TSH 55 mU/L (0.4-5.0)

What is the most likely diagnosis in this patient?

- 1- De Quervain's thyroiditis
- 2- Hashimoto's thyroiditis
- 3- Iodine deficiency
- 4- Penderd's syndrome
- 5- primary atrophic hypothyroidism

Answer & Comments

Answer: 2- Hashimoto's thyroiditis

Irrespective of gender, the most likely diagnosis in this hypothyroid man is Hashimoto's disease. Iodine deficiency is extremely unlikely in the UK and elevated De Quervain's thyroiditis would be associated with acute presentation with a painful goitre, raised temperature and weight loss. TFTs may be transiently abnormal often high but hypothyroidism may ensue. Pendred's

syndrome is hypothyroidism due to dysmorphogenesis, goitre and sensorineural deafness. Atrophic hypothyroidism would not be associated with goitre.

[Q: 591] OnExamination - Endocrinology

A 55 year-old female complaining of vague tiredness is found to have a serum corrected calcium concentration of 2.9 mmol/l. Examination was unremarkable.

Which of the following results confirms the suspected diagnosis of primary hyperparathyroidism?

- 1- High normal 1,25-dihydroxyvitamin D concentration
- 2- High normal 24 hour urinary calcium concentration
- 3- High normal plasma parathyroid hormone concentration
- 4- Low normal plasma phosphate concentration
- 5- Low normal serum 25-hydroxyvitamin D concentration

Answer & Comments

Answer: 3- High normal plasma parathyroid hormone concentration

Bit too easy really. A high or even normal PTH concentration in the presence of hypercalcaemia would support the diagnosis of hyperparathyroidism. A high urinary Calcium concentration may be expected as would a low plasma phosphate but neither confirm the diagnosis. Elevated 1,25 VitD suggests a diagnosis of hypervitaminosis D.

[Q: 592] OnExamination - Endocrinology

In which of the following conditions would it be expected to find an elevated plasma total cortisol concentration?

- 1- congenital adrenal hyperplasia
- 2- patients on long-term benzodiazepine therapy
- 3- patients taking prednisolone
- 4- pregnancy
- 5- primary aldosteronism

Answer & Comments

Answer: 4- pregnancy

Cortisol levels are increased in pregnancy, conditions of physical and emotional stress and drug therapy (oestrogens, oral contraceptives, amphetamines, cortisone, and spironolactone). Treatment with other forms of steroid lead to decreased levels of cortisol.

[Q: 593] OnExamination - Endocrinology

A 45-year-old man presents with headaches and low libido. He is found to be hypopituitary. The CT scan shows a pituitary tumour with suprasellar extension.

Which of the following structures is likely to be compressed?

- 1- Abducens nerve
- 2- Hypothalamus
- 3- Oculomotor nerve
- 4- 3rd Ventricle
- 5- Optic nerve

Answer & Comments

Answer: 5- Optic nerve

Superior extension of the tumour can lead to compression or invasion of the optic apparatus or the hypothalamus. Lateral extension of the tumour with compression or invasion of the cavernous sinus can compromise third, fourth, or sixth cranial nerve functions, manifest as diplopia in 5 to 15% of pituitary tumour patients. The optic

chiasm lies 5-10mm above the diaphragm sellae and anterior to the stalk. Adenomas larger than 1.5cm frequently have suprasellar extension, and an MRI scan will show compression and upward displacement of the optic chiasm.

[Q: 594] OnExamination - Endocrinology

A 26-year-old man presented with polydipsia and polyuria for the last 2 years.

Investigations:

serum urea 8.4 mmol/L (2.5-7.5)

serum creatinine 108 µmol/L (60-110)

serum corrected calcium 2.82 mmol/L (2.2-2.6)

serum phosphate 0.73 mmol/L (0.8-1.4)

plasma parathyroid hormone 6.8 pmol/L (0.9-5.4)

Which of the following is directly responsible for his increased intestinal calcium reabsorption?

- 1- 1,25 dihydroxy vitamin D
- 2- 25 hydroxy vitamin D
- 3- calcitonin
- 4- hypophosphatemia
- 5- parathyroid hormone

Answer & Comments

Answer: 1- 1,25 dihydroxy vitamin D

This patient has hypercalcaemia due to hyperparathyroidism. However, the intestinal absorption of calcium is facilitated by 1,25 dihydroxyVitamin D.

[Q: 595] OnExamination - Endocrinology

Which of the following is true concerning oral hypoglycaemic agents?

- 1- Acarbose promotes insulin secretion in response to meals
- 2- Chlorpropamide induces liver enzymes
- 3- Glibenclamide is excreted unchanged by the kidney
- 4- Gliclazide inhibits gluconeogenesis
- 5- Metformin inhibits hepatic gluconeogenesis

Answer & Comments

Answer: 5- Metformin inhibits hepatic gluconeogenesis

Chlorpropamide like all the other sulphonylureas stimulate pancreatic insulin secretion. They are not liver enzyme inducers but are affected by liver enzyme inducers and inhibitors. They undergo hepatic metabolism then renal excretion. Acarbose is an alpha glucosidase inhibitor which inhibits the splitting of disaccharides into glucose and so inhibits glucose absorption from the gut. Metformin is an insulin sensitiser and although its actions are not fully understood its main role appears to be through inhibition of hepatic gluconeogenesis.

[Q: 596] OnExamination - Endocrinology

A 51-year-old woman presented with nocturia and Pruritis vulvae. Investigations revealed:
urine dipstick analysis glucose 2%

Which one of the following would most reliably confirm a diagnosis of diabetes mellitus?

- 1- Elevated glycated haemoglobin concentration
- 2- Fasting plasma glucose of 6.7 mmol/L (3.0-6.0)
- 3- 50g oral glucose tolerance test
- 4- Random plasma glucose of 8.3 mmol/L
- 5- Two hour post-prandial plasma glucose of 12 mmol/L (<11.1)

Answer & Comments

Answer: 5- Two hour post-prandial plasma glucose of 12 mmol/L (<11.1)

The post-prandial glucose gives an equivalent to the 75g glucose tolerance test, which would be one of the investigations of choice in this patient. None of the other results listed here formally confirm the diagnosis of Type 2 diabetes.

[Q: 597] OnExamination - Endocrinology

Which one of the following statements applies to an infant with undiagnosed congenital hypothyroidism.

- 1- they may be asymptomatic
- 2- haemolytic jaundice occurs
- 3- they may later have early acceleration of bone age and short stature at maturity
- 4- gastrointestinal disturbances, especially diarrhoea may develop
- 5- Tachyarrhythmias may occur.

Answer & Comments

Answer: 1- they may be asymptomatic

Lack of symptoms may be a feature. Prolonged conjugated hyperbilirubinaemia is seen with this condition. Bone age and growth will be delayed. Constipation rather than diarrhoea is observed. Bradycardia may occur, but tachyarrhythmias are not associated.

[Q: 598] OnExamination - Endocrinology

Maturity onset diabetes of the young (MODY) is due to which of the following:

- 1- BRCA1 and BRCA2 (breast cancer) gene products
- 2- HOX (homeobox) gene family
- 3- Leptin mutations

- 4- Stargardt's disease mutations
5- Glucokinase mutations

Answer & Comments

Answer: 5- Glucokinase mutations

MODY is an autosomal dominantly inherited form of diabetes and is due to glucokinase mutations. Other causes of MODY include Hepatocyte Nuclear Factor (HNF) gene mutations.

[Q: 599] OnExamination - Endocrinology

Useful therapy for improving fertility in Polycystic ovarian syndrome include

- 1- Cyproterone acetate
2- Ethinyl oestradiol
3- Metformin
4- Glibenclamide
5- Spironolactone

Answer & Comments

Answer: 3- Metformin

Metformin has been shown to increase the rate of conception in PCOs through improved insulin sensitivity. Ethinylloestradiol and cyproterone acetate combine to form Dianette the oral contraceptive. Spironolactone is used for hirsutism but is teratogenic. Glibenclamide is not used in PCOs.

[Q: 600] OnExamination - Endocrinology

A 56-year-old male presents with a 5 year history of increased sweats and change in shoe size. Examination reveals prognathism and macroglossia, with large hands. Blood pressure is 180/94 mmHg but visual field examination is full to confrontation.

Which of the following tests would be diagnostic?

- 1- Oral glucose tolerance test
2- TRH test
3- Insulin tolerance test
4- Pituitary MRI
5- IGF-1 concentration

Answer & Comments

Answer: 1- Oral glucose tolerance test

The diagnosis of acromegaly is confirmed with a failure of GH suppression during an oral glucose tolerance test. Though a pituitary adenoma may be present it is not diagnostic of acromegaly.

[Q: 601] OnExamination - Endocrinology

A 17-year-old female who is 16 weeks pregnant reports that her elder brother has vitamin D resistant rickets.

What is the most likely mode of inheritance of this condition?

- 1- Autosomal dominant
2- Autosomal dominant with incomplete penetrance
3- Autosomal recessive
4- X-linked dominant
5- X-linked recessive

Answer & Comments

Answer: 4- X-linked dominant

Vitamin D resistant rickets is inherited in an X-linked dominant manner. Therefore an affected female will transmit the disease to 50% of her sons and 50% of her daughters. An affected male will transmit the condition to all of his daughters but none of his sons. In this case as the mother is unaffected, therefore

there is no risk of the condition being passed to her unborn child.

[Q: 602] OnExamination - Endocrinology

Which of the following is a characteristic feature of primary hyperaldosteronism?

- 1- Gross oedema
- 2- Hyponatraemia
- 3- Muscular weakness
- 4- Oliguria
- 5- Vitiligo

Answer & Comments

Answer: 3- Muscular weakness

Primary hyperaldosteronism or conn's syndrome is characterised by hypokalaemic hypertension. Patients can present with tetany (alkalosis) and muscle weakness (hypokalaemia). Oedema, oliguria are more features of secondary hyperaldosteronism (cirrhosis) and vitiligo (suggesting auto-immunity) is not a feature.

[Q: 603] OnExamination - Endocrinology

A 40-year-old female, with no prior history of thyroid disease, presents with a 5 day history of an acutely painful, left-sided goitre. Clinically she appeared euthyroid, and was afebrile.

Investigations revealed the following

haemoglobin 13.0 g/dL

white cell count $7.0 \times 10^9/L$

platelet count 200

What is the most likely diagnosis?

- 1- De Quervain's thyroiditis
- 2- Haemorrhage into a cyst
- 3- Hashimoto's thyroiditis
- 4- Staphylococcal abscess

5- Thyroid carcinoma

Answer & Comments

Answer: 2- Haemorrhage into a cyst

The left side of this patient's goitre becomes acutely swollen with no other signs and FBC is normal which suggests acute haemorrhage into a cyst. Thyroid cancer is usually painless. De Quervain's thyroiditis is a diffusely tender goitre typically with systemic features such as weight loss, pyrexia and a raised ESR.

[Q: 604] OnExamination - Endocrinology

A 42-year-old male with a 15 year history of type 1 diabetes presents with a two month history of deteriorating pain and stiffness of the right shoulder. On examination he has painful limitation of internal rotation and can abduct the right arm to only 90 degrees. Flexion is relatively unimpaired. There is some weakness of movement of that shoulder with slight wasting of shoulder muscles. He has some reduced vibration sensation in both hands.

Which of the following is the most likely diagnosis?

- 1- Adhesive capsulitis
- 2- Brachial plexopathy
- 3- Calcium pyrophosphate arthropathy
- 4- Diabetic arthropathy
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 1- Adhesive capsulitis

This patient has typical features of a frozen shoulder and this is typified by the reduced internal rotation and abduction of the shoulder. Slight wasting due to pain and reduced use of the shoulder muscles is expected. Brachial plexopathy is associated with involvement of the brachial plexus with

associated specific dermatomal loss of sensation (not the peripheral neuropathy associated with diabetes as in this case) as well as specific loss of strength (not often the shoulder) such as wrist drop, ulna nerve palsy etc.

[Q: 605] OnExamination - Endocrinology

A 29-year-old female student nurse presents with a discrete thyroid swelling. An isotope scan reveals it to be a "cold nodule". She has scattered local cervical lymphadenopathy.

What is the likely diagnosis?

- 1- Anaplastic carcinoma
- 2- Graves disease
- 3- Medullary carcinoma
- 4- Papillary carcinoma
- 5- Subacute thyroiditis

Answer & Comments

Answer: 4- Papillary carcinoma

Papillary carcinoma makes up 75% of thyroid tumours, and this patients age (<45) puts her in a low risk group. Usually these tumours present as "cold nodules" on isotope scanning. These cancers may extend by intraglandular spread or local lymph node invasion. They are slow growing, but may become more aggressive, spreading locally or metastasising, especially to the lung. Anaplastic carcinoma is very aggressive and more common in elderly subjects. Subacute thyroiditis presents with moderate thyroid enlargement, fever, malaise and neck pain. The gland is tender, and there may be signs of thyrotoxicosis.

[Q: 606] OnExamination - Endocrinology

A 38-year-old man presented with intermittent severe headaches. He was prescribed Spironolactone 50mg and

Bendroflumethiazide 2.5mg daily for hypertension. On examination his pulse was 112 beats per minute, with regular rhythm, and blood pressure was 190/110 mmHg. Investigations revealed:

serum sodium 132 mmol/L (137-144)

serum potassium 3.4 mmol/L (3.5-4.9)

serum urea 7.0 mmol/L (2.5-7.5)

Which one of the following is the most useful investigation in establishing the diagnosis?

- 1- A 24 hour urinary 5-hydroxyindoleacetic acid concentration
- 2- A 24 hour urinary catecholamine concentration
- 3- A 24 hour urinary free cortisol concentration
- 4- A radionuclide hippuran renogram
- 5- The serum aldosterone: rennin ratio

Answer & Comments

Answer: 2- A 24 hour urinary catecholamine concentration

This question is typical of an MRCP question which may be used as a "good discriminatory question"! It seems nebulous at first, but on further investigation it is extremely complex. One can imagine the smirks of the old gentlemen in the college at the post-exam port soiree.

The answer is unlikely to be carcinoid given the lack of symptoms of carcinoid syndrome. The flushing attacks of the carcinoid syndrome are accompanied by hypotension. Renal anatomy and function is studied with sequential images using radionuclides that are indexes of tubular function (¹³¹I Hippuran). The clinical history here is not suggestive of renal artery stenosis.

Given the patients' young age, and markedly raised BP on treatment, we should consider an endocrine cause. The electrolyte disturbance is mild, and is of dubious relevance in this

question. Diuretic use may be causing the hyponatraemia and hypokalaemia, indeed the commonest cause of hypokalaemia in hypertension is diuretic therapy. However, spironalactone use could, theoretically, mask a more significant hypokalaemia.

There is no clinical history to suggest Cushing's, and primary aldosteronism is not associated with a tachycardia. An aldosterone:rennin ratio would not be appropriate at this stage given that the patient is receiving spironalactone.

The history of episodic headaches is central to this question, together with the tachycardia. These paroxysmal headaches suggest the diagnosis of pheochromocytoma; often the symptoms are vague, and rarely is the classical presentation encountered.

Patients with pheochromocytoma may develop a severe vascular headache (Bridgwater and Starling, 1982). Thomas et al. (1966) reviewed the histories of 100 patients with proven pheochromocytoma seen at the Mayo Clinic and found that episodic headache was present in 80%. It was usually of rapid onset, bilateral, severe, throbbing, and associated with nausea in about half of the cases.

[Q: 607] OnExamination - Endocrinology

A 53-year-old woman presented asking for treatment to prevent osteoporosis. She was one year post-menopausal, is aware of flushes at night and has a family history of osteoporosis.

Which one of the following therapies would be most appropriate?

- 1- Calcium and vitamin D supplements
- 2- Continuous oestrogen
- 3- Cyclical etidronate and calcium
- 4- Cyclical oestrogen and progestogen
- 5- Vitamin D supplements

Answer & Comments

Answer: 4- Cyclical oestrogen and progestogen

This patient with a family history of osteoporosis is one year post-menopausal and has symptoms. Calcium and Vit D supplements with a good diet would be unnecessary and are unproven in this age group. There is no suggestion that she has had a hysterectomy and so an unopposed oestrogen would be contra-indicated. Etidronate is licensed for the prevention of further osteoporotic fractures, prophylaxis against corticosteroid induced osteoporosis and use when HRT is contra-indicated. In this patient's case, and in the absence of any specific contra-indications ?Thromboembolic disease, breast Ca, combined HRT would be the treatment of choice despite the recent literature indicating increased risk of vascular disease. One would use HRT in the symptomatic (menopausal symptoms) but not in the asymptomatic where possibly bisphosphonates would be preferred.

[Q: 608] OnExamination - Endocrinology

A 45-year-old woman presents to A+E complaining of a severe headache and vomiting for 12 hours. She was previously well and takes no medication. On examination, her temperature was 37.5C, her pulse rate was 110 beats per minute and her blood pressure was 95/60 mmHg. There was some neck stiffness and there was a right third nerve palsy with papillary involvement. Her initial investigations show.

Haemoglobin 13.6 g/dl

White cell count 14.5 x 10⁹/L

Platelets >450 x 10⁹/L

Sodium 122 mmol/l (137-144 mmol/L)

Potassium 5.2 mmol/L (3.5-4.9 mmol/L)

Urea 4.6mmol/l (3.0-6.5mmol/l)

Creatinine 85 µmol/l (60-125 µmol/l)

Random cortisol 150 nmol/L (200-700 nmol/L)
 TSH 1.1 mU/L (0.4-5 mU/L)
 Free T₄ 9 pmol/L (10-22 pmol/L)
 Prolactin 350 (<450mU/L)

What is the most likely diagnosis?

- 1- Encephalitis
- 2- Migraine
- 3- Meningitis
- 4- Pituitary apoplexy
- 5- Subarachnoid Haemorrhage

Answer & Comments

Answer: 4- Pituitary apoplexy

This patient has had an acute onset of headache secondary to haemorrhage into the pituitary gland. She has evidence of hypopituitarism given her low random cortisol, with consistent biochemical results of hyponatraemia and hyperkalaemia. Her 3rd cranial nerve palsy is due to enlargement of the pituitary producing compression of the 3rd cranial nerve. She requires resuscitation and steroid replacement, urgent imaging of the pituitary gland and consideration of neurosurgical decompression.

[Q: 609] OnExamination - Endocrinology

In the treatment of Congenital Adrenal Hyperplasia, which of the following statements is correct?

- 1- Hydrocortisone may be administered once daily
- 2- Preferred treatment in children is prednisone
- 3- Efficacy of treatment is best monitored by 17-OH progesterone and androstenedione levels
- 4- Renin activity levels are of no clinical use in treatment monitoring

- 5- Hypotension, hyperkalaemia and hyperreninaemia suggest that the dose of mineralocorticoid should be reduced

Answer & Comments

Answer: 3- Efficacy of treatment is best monitored by 17-OH progesterone and androstenedione levels

In the treatment of CAH the lowest dose of glucocorticoid that suppresses (not totally) Adrenal androgens, whilst maintaining normal growth and weight gain. Renin activity levels can be used to monitor adequacy of mineralocorticoid and sodium replacement.

Hydrocortisone has a relatively short half-life and must therefore be administered twice daily, whilst the preferred mode of glucocorticoid replacement in children is hydrocortisone as it minimises growth suppression. Over treatment with mineralocorticoids leads to hypertension, suppressed plasma rennin activity and possibly growth retardation.

[Q: 610] OnExamination - Endocrinology

Growth hormone deficiency is noted in:

- 1- Turner's syndrome
- 2- Constitutional short stature
- 3- Laron's syndrome
- 4- Sheehan's syndrome
- 5- Chronic renal failure

Answer & Comments

Answer: 4- Sheehan's syndrome

Sheehan's syndrome is post-delivery infarction of the pituitary and GHD is typical. Although GH therapy is used in CRF, Turner's syndrome and short stature, subjects are not GH deficient. Laron's syndrome is due to a GH receptor defect with impaired IGF-1 production.

[Q: 611] OnExamination -
Endocrinology

A 70 year-old female is diagnosed with anaplastic thyroid cancer.

What is the most likely consequence of this cancer?

- 1- Brain metastases
- 2- Hypercalcaemia from bony metastases
- 3- Liver metastases
- 4- Lung metastases
- 5- Upper airways obstruction

Answer & Comments

Answer: 5- Upper airways obstruction

Anaplastic thyroid cancer carries a very poor prognosis with the vast majority (~90%) having local invasion (cervical lymph glands) and local infiltration, (particularly the trachea) at diagnosis. Lung and bone metastases are common at presentation ~ 50%. Upper airways obstruction frequently requires tracheostomy.

[Q: 612] OnExamination -
Endocrinology

Which of the following is regarded as a physiological effect of thyroid hormones?

- 1- Decrease gluconeogenesis
- 2- Enhance insulin sensitivity
- 3- Reduce myocardial oxygen demand
- 4- Reduce nerve conduction
- 5- Reduce oxidation of fatty acids in tissues

Answer & Comments

Answer: 2- Enhance insulin sensitivity

Thyroid hormones enhance insulin-dependent entry of glucose into cells, myocardial oxygen consumption, nerve conduction, gluconeogenesis and oxidation of fatty acids

[Q: 613] OnExamination -
Endocrinology

A 51-year-old man is found to have bilateral breast enlargement. He says that this is normal for him and that he has not noted any change in years. He shaves infrequently and has scant pubic hair.

Which of the following is most likely to be present?

- 1- 47, XXY karyotype
- 2- History of antidepressant drug therapy
- 3- Increased risk for breast carcinoma
- 4- Increased testosterone levels
- 5- Seminoma of the testis

Answer & Comments

Answer: 1- 47, XXY karyotype

Gynaecomastia is common with Klinefelter's syndrome. Male breast cancer is rare and is more often associated with advanced age. There is an association between gynaecomastia and some functioning testicular tumors such as Leydig cell tumors (or rarely, Sertoli cell tumors). Gynaecomastia is related to conditions of high oestrogens, and one of the most common causes for this is cirrhosis of the liver in chronic alcoholics.

[Q: 614] OnExamination -
Endocrinology

An 18-year-old female with polycystic ovary syndrome was prescribed Metformin.

What is the most important pharmacological action of Metformin in this situation?

- 1- Increasing insulin levels
- 2- Increasing luteinising hormone levels
- 3- Increasing oestradiol levels
- 4- Increasing peripheral glucose uptake
- 5- Increasing gluconeogenesis

Answer & Comments

Answer: 4- Increasing peripheral glucose uptake

Lowering serum insulin concentrations with metformin ameliorates hyperandrogenism, by reduction of ovarian enzyme activity that results in ovarian androgen production.

Clinical studies have shown that metformin reduces insulin resistance, and have demonstrated a fall in serum androgens, luteinising hormone and weight. The reduced insulin resistance is associated with reduced insulin drive to the insulin sensitive ovary in polycystic ovarian syndrome and hence reduces androgen production.

[Q: 615] OnExamination - Endocrinology

A 51-year-old district nurse presented with a history of near fainting episodes, which were promptly relieved by eating chocolates. At her last hospital admission, her simultaneous blood results were as follows:

plasma glucose 1.8 mmol/L

serum insulin 58 pmol/L (<21)

c-peptide undetectable

What is the most likely diagnosis?

- 1- alcohol induced hypoglycaemia
- 2- exogenous insulin administration
- 3- growth hormone deficiency
- 4- insulinoma
- 5- sulfonylurea induced hypoglycaemia

Answer & Comments

Answer: 2- exogenous insulin administration

The story of a middle aged woman who has spontaneous hypoglycaemia and inappropriately high insulin (should be undetectable in presence of hypoglycaemia) would suggest insulinoma. Yet, the c-peptide

is undetectable (indicating she has been administering insulin as the c-peptide is released with endogenous insulin) and her occupation suggests drug abuse - in this case insulin.

[Q: 616] OnExamination - Endocrinology

A 30-year-old female presents with mild galactorrhoea. Biochemistry reveals an elevated prolactin of 1200 mu/l (NR 50-450) and an oestradiol concentration of 100 pmol/l (NR 130-450).

Which of the following is the likely cause?

- 1- Addison's disease
- 2- Hyperthyroidism
- 3- Non-functioning pituitary tumour
- 4- Sheehan's syndrome
- 5- Post-cranial irradiation for acute lymphocytic leukaemia as a child

Answer & Comments

Answer: 3- Non-functioning pituitary tumour

Addison's may be associated with hypogonadism but prolactin concentrations are usually normal. Severe hypothyroidism is associated with HyperPRL hypogonadism. A NFPT may cause hyperprolactinaemia through stalk compression. Sheehan's syndrome is associated with a low prolactin concentration. Cranial irradiation may initially cause hyperprolactinaemia but a low PRL is typical after a year.

[Q: 617] OnExamination - Endocrinology

A patient is receiving treatment with recombinant human growth hormone.

Which of the following is a recognised side effect of GH therapy?

- 1- Prostatic hypertrophy

- 2- Melanoma
- 3- Benign intra-cranial hypertension
- 4- Prolongation of the QT interval
- 5- Osteoporosis

Answer & Comments

Answer: 3- Benign intra-cranial hypertension

GH is rarely associated with BIH, the mechanism probably is related to fluid retention. The commonest side effect of GH therapy is fluid retention, though other side effects include gynaecomastia, hypertension and atrial fibrillation. BPH has not been reported.

[Q: 618] OnExamination - Endocrinology

Leptin

- 1- Is synthesised in the hypothalamus
- 2- Reduces Basal metabolic rate
- 3- Acts upon the adipocyte
- 4- Produces satiety
- 5- Plasma concentrations correlate directly with lean body mass.

Answer & Comments

Answer: 4- Produces satiety

Leptin is synthesised within the adipocyte and plasma concentrations are directly related to adipocyte (fat) mass. It acts on centres within the hypothalamus to produce satiety.

[Q: 619] OnExamination - Endocrinology

A 47-year-old female of Asian origin presents with a long history of deteriorating weakness and fatigue. Of late, she has difficulty ascending stairs at home need to crawl up them. She has a six year history of type 2 diabetes mellitus and is treated with Metformin and Gliclazide.

Initial X-rays reveal healing clavicular fractures, and a superior pubic rami fracture.

Her investigations show:

Calcium 2.2 mmol/l (2.2 - 2.5 mmol/l)

Phosphate 0.7 mmol/l (0.8 - 1.5 mmol/l)

Alkaline Phosphatase 212 iu/l (50 - 110 IU/L)

AST 30 iu/l (5 - 40 IU/l)

Urea 12 mmol/l (3 - 8 mmol/l)

Creatinine 67 µmol/l (50 - 100 µmol/L)

HbA1c 11.0% (4 - 6%)

What is the likely diagnosis?

- 1- Advanced diabetic renal disease
- 2- Diabetic amyotrophy
- 3- Hypoparathyroidism
- 4- Osteoporosis
- 5- Vitamin D deficiency

Answer & Comments

Answer: 5- Vitamin D deficiency

This patient has vitamin D deficiency. It classically presents in the female Asian population whose clothing offers little exposure to sunlight. The phosphate and calcium are usually low normal, and the alkaline phosphatase is high. Bone deformity ?rickets may develop in children. Fractures can occur due to bone demineralisation with osteoporosis on DEXA. Proximal myopathy is often a presenting feature of osteomalacia as is probably the case with this patient.

[Q: 620] OnExamination - Endocrinology

A 55-year-old female who received radioactive iodine over five years ago presents for annual thyroid function assessment. She is well and takes no medication.

Her results reveal:

Free Thyroxine 13.2 pmol/l (9.8 - 23)

TSH 16 mU/l (0.5-4.5 mU/l)

Total cholesterol 6.8 mmol/l (<5 mmol/l)

Plasma triglycerides 2.2 mmol/l (<2 mmol/l)

What is the most appropriate treatment for this patient's dyslipidaemia?

- 1- Cholestyramine
- 2- Fibrate therapy
- 3- Hormone replacement therapy
- 4- Statin therapy
- 5- Thyroxine

Answer & Comments

Answer: 5- Thyroxine

This patient has subclinical hypothyroidism as reflected by the normal T4 but elevated TSH. A hypercholesterolaemia with hypertriglyceridaemia is frequently associated due to impaired lipoprotein lipase function. The dyslipidaemia may well resolve following the appropriate replacement with thyroxine.

[Q: 621] OnExamination - Endocrinology

Which of the following has a known association with phenylketonuria?

- 1- Presentation in the second year of life with absence seizures.
- 2- The association of red hair and brown eyes.
- 3- Normal development.
- 4- Musty odour.
- 5- Response of some patients to piridoxine.

Answer & Comments

Answer: 4- Musty odour.

Phenylketonuria is a quarter as common as congenital hypothyroidism, with an incidence of 1:10,000 live births. It is due either to phenylalanine hydroxylase deficiency or problems with synthesis or recycling of the

bioptine co-factor. The presentation is with infantile spasms or developmental delay between 6 and 12 months of age. Patients may be musty smelling, fair haired and blue eyed and may develop eczema. Treatment is with restriction of dietary phenylalanine, while ensuring sufficient for physical and neurological growth. Co-factor defects are treated with a diet low in phenylalanine and high in neurotransmitter precursors.

[Q: 622] OnExamination - Endocrinology

A 35 year-old woman presented with a five year history of weight gain associated with a one year history of amenorrhoea. Over this time she had also noticed hirsutism and had been trying to conceive. On examination, she had a BMI of 32 kg/m², a pulse was 84 beats per minute, and a blood pressure of 154/100 mmHg. Features suggestive of Cushing's syndrome were also noted.

Which of the following would be the most useful initial investigation?

- 1- 24 hour urinary free cortisol concentration
- 2- Combined 9am ACTH concentration and serum cortisol concentration
- 3- Midnight cortisol concentration
- 4- Serum sodium and potassium concentrations
- 5- The 1mg overnight dexamethasone suppression test

Answer & Comments

Answer: 1- 24 hour urinary free cortisol concentration

A ridiculous question! Totally unfair expecting candidates to know which screening test is better ?1 mg ODST or UFC. Either test would be appropriate, but UFC is often recommended and has a 95% specificity (85% specificity in the obese) and a 98% sensitivity. The ODST has a sensitivity and specificity of

98% and 75-80% in obese subjects with a cut-off value of 50 nmol/l. Therefore, purely for convenience sake a UFC would probably be the expected response here. Midnight cortisol is pointless as a screening test expecting the patient to be fast asleep when blood is taken. Sodium and Potassium concentrations offer nothing, nor do ACTH and cortisol.

[Q: 623] OnExamination - Endocrinology

Which of the following is a likely presenting feature of Cushing's syndrome

- 1- Lichen planus
- 2- Mononeuritis multiplex
- 3- Polymyositis
- 4- Necrosis of the femoral head
- 5- Diabetes insipidus

Answer & Comments

Answer: 4- Necrosis of the femoral head

Cases of Cushing's Syndrome have presented with necrosis of the femoral head due to osteoporosis. Diabetes insipidus would be very unusual, whereas diabetes mellitus may occur in 30%. Lichen planus is treated with corticosteroids, as is polymyositis. Mononeuritis multiplex is not a feature.

[Q: 624] OnExamination - Endocrinology

A 53-year-old female with surgically treated acromegaly is receiving treatment with Octreotide therapy due to persistently elevated growth hormone concentrations following surgery.

What is the mechanism of action of Octreotide?

- 1- Inhibition growth hormone receptor
- 2- Inhibition of dopamine D2 receptor
- 3- Inhibition of IGF-1 receptor

- 4- Inhibition of GHRH receptor
- 5- Stimulation of the somatostatin receptor

Answer & Comments

Answer: 5- Stimulation of the somatostatin receptor

Octreotide is a somatostatin analogue and directly inhibits growth hormone secretion through interaction with its receptors. It is also used in the treatment of neuroendocrine tumours such as carcinoid tumours again through interaction with somatostatin receptors.

[Q: 625] OnExamination - Endocrinology

A 63-year-old male with a five year history of diet controlled type 2 diabetes presents with deteriorating glycaemic control and is started on treatment to control his hyperglycaemia. Then, later, he presents with dyspnoea and orthopnoea. He is diagnosed with left ventricular failure.

Which of the following drugs used in the control of his hyperglycaemia may have contributed to this episode of heart failure?

- 1- Glibenclamide
- 2- Glimiperide
- 3- Insulin glargine
- 4- Metformin
- 5- Rosiglitazone

Answer & Comments

Answer: 5- Rosiglitazone

Glitazone treatment is associated with fluid retention and consequently may exacerbate/precipitate heart failure. This was a key finding in the PROACTIVE study which is one of the largest glitazone trials to have been reported.

Metformin is relatively safe in stable heart failure but must be used in caution with those prone to deterioration in renal function.

[Q: 626] OnExamination - Endocrinology

A 70 year-old female presents with a six month history of frontal headaches and weight loss. On examination a bitemporal hemianopia was noted.

Which of the following suggest the diagnosis of a pituitary tumour?

- 1- 9am cortisol concentration of 350 nmol/L (200 - 700)
- 2- LH concentration of 44 uL (>30)
- 3- Prolactin concentration of 580 mU/L (50-550)
- 4- Random growth hormone concentration 1.2 mU/L (< 1)
- 5- TSH concentration of 3.8 mU/L (0.5 - 4.5)

Answer & Comments

Answer: 3- Prolactin concentration of 580 mU/L (50-550)

The raised prolactin would most likely reflect stalk compression in this patient. Otherwise, the normal cortisol would be unhelpful as is the normal TSH. The elevated LH is a reflection of this patient being menopausal. GH concentrations are frequently undetectable as it is released episodically usually during the night.

[Q: 627] OnExamination - Endocrinology

A 38-year-old male presents with concerns relating to obesity.

What is the average daily energy used by a male of this age?

- 1- 1500 kcal
- 2- 2000 kcal

- 3- 2500 kcal
- 4- 3000 kcal
- 5- 3500 kcal

Answer & Comments

Answer: 3- 2500 kcal

The average daily energy consumption of a male is 2500 kcal and 2000 kcal for a female. These values are important when determining the dietary calorie restriction.

[Q: 628] OnExamination - Endocrinology

A 32-year-old female presents with a 2 month history of agitation, menstrual irregularity and weight loss. Examination reveals a tremor and a palpable goitre with a bruit.

Which of the following would most likely be present in this patient:

- 1- Thyroid microsomal antibodies
- 2- Thyroid peroxidase antibodies
- 3- TSH receptor stimulating antibodies
- 4- TSH receptor inhibiting antibodies
- 5- Anti-thyroglobulin antibody

Answer & Comments

Answer: 3- TSH receptor stimulating antibodies

This patient is most likely to have Graves' disease as revealed by the thyroid bruit. TSH receptor stimulating antibody is specific for Graves' disease and is present in the vast majority of cases.

[Q: 629] OnExamination - Endocrinology

Low uptake of ¹²³I on the thyroid uptake scan would be an expected finding in:

- 1- A solitary toxic nodule
- 2- A multi-nodular toxic goitre

- 3- Amiodarone induced thyrotoxicosis type 1
- 4- DeQuervain's thyroiditis
- 5- Graves' thyrotoxicosis

Answer & Comments

Answer: 4- DeQuervain's thyroiditis

DeQuervain's thyroiditis is classically associated with low or absent ^{123}I (or ^{131}I radioactive isotopes of iodine) uptake. The others will have high or normal uptake. In particular type 1 amiodarone induced thyrotoxicosis may be distinguished from the thyroiditis of type 2 by the normal or high uptake scan.

[Q: 630] OnExamination - Endocrinology

A 32-year-old woman presents with a four month history of amenorrhoea. She takes no specific therapy. She has two children and her husband has a vasectomy. Examination reveals an obese individual but no other abnormality.

Investigations reveal:

Serum oestradiol 100 pmol/L (NR 130 - 500)

Serum LH 2.1 mU/L (NR 3.0 - 6.6)

Serum FSH 2.2 mU/L (NR 3.3 - 10.1)

Serum prolactin 800 mU/L (NR 50 - 500)

Serum testosterone 2.1 pmol/L (NR < 3.0)

Which investigation is the most appropriate?

- 1- Insulin tolerance test
- 2- Pregnancy test
- 3- 17 hydroxy-progesterone
- 4- Urine free cortisol concentration
- 5- Magnetic resonance imaging (MRI) of the pituitary

Answer & Comments

Answer: 5- Magnetic resonance imaging (MRI) of the pituitary

This patient has hypogonadotrophic hypogonadism as evidenced by suppressed LH/FSH and a low oestradiol concentration. This would exclude pregnancy as a cause and polycystic ovarian syndrome is also unlikely. In the presence of a raised prolactin concentration, a microprolactinoma would be the most likely explanation for this patient's symptoms and results. This may be demonstrated by a pituitary MRI scan. An insulin tolerance test would usually be entirely normal in a microprolactinoma.

[Q: 631] OnExamination - Endocrinology

A 17 year-old male student presents with a three week history of thirst, polyuria, balanitis and weight loss.

What is the most appropriate next investigation?

- 1- 75 g glucose tolerance test
- 2- Fructosamine concentration
- 3- HbA1c
- 4- Random plasma glucose concentration
- 5- Urinary ketones

Answer & Comments

Answer: 4- Random plasma glucose concentration

This patient obviously has diabetes mellitus and the diagnosis should be confirmed with either a fasting plasma glucose above 7 mmol/l or a random plasma glucose above 11.1 mmol/l.

[Q: 632] OnExamination - Endocrinology

A 53-year-old female presents with a four

month history of weight gain, episodic sweats and shakiness which occur during episodes of fasting and is relieved by eating chocolate bars. She informs you that she has a friend who is a nurse and has provided her with a glucose meter. During one of these episodes the glucose concentration was recorded at 2.8 mmol/l. On examination she has a body mass index of 30.2 kg/m², has a pulse of 82 bpm and a blood pressure of 144/86 mmHg. No other abnormalities are noted.

Which of the following is the most appropriate next investigation for this woman?

- 1- 72 hour fast
- 2- Fasting insulin and c-peptide measurement
- 3- MRI pancreas
- 4- Oral glucose tolerance test
- 5- Sulphonylurea measurement

Answer & Comments

Answer: 1- 72 hour fast

This woman has features of spontaneous hypoglycaemia which is relieved by eating and precipitated by fast and exercise. The most relevant investigation to prove or disprove this would be a 72 hr fast which has a virtual 99% sensitivity. If proven then further investigation for an insulinoma or factitious hypoglycaemia is warranted.

[Q: 633] OnExamination - Endocrinology

On routine screening of a 50-year-old woman who complained of tiredness, she is found to be hypercalcaemic. She is being treated for manic depression, and cardiac failure.

Which of the following is most likely to be the cause of the raised calcium?

- 1- ACE Inhibitor therapy
- 2- Furosemide therapy
- 3- Lithium therapy

- 4- Seroxat treatment
- 5- Vitamin D deficiency

Answer & Comments

Answer: 3- Lithium therapy

Lithium can produce Diabetes Insipidus and also raise calcium. Neither Seroxat nor ACE Inhibitors are related to hypercalcaemia. Excess of vitamin D causes elevated calcium. Furosemide lowers calcium but thiazides reduce excretion and so can exacerbate hypercalcaemia.

[Q: 634] OnExamination - Endocrinology

A 57-year-old male diabetic requests Sildenafil for erectile dysfunction.

Which of the following are contraindicated with Sildenafil?

- 1- Carbamazepine
- 2- Carvedilol
- 3- Indomethacin
- 4- Nicorandil
- 5- Valsartan

Answer & Comments

Answer: 4- Nicorandil

Sildenafil is contraindicated if the patient is taking nitrates, or nitrate derivatives (nicorandil). We are informed on the prescribing information that if the patient takes nitrates then they should be stopped for the period during which Sildenafil is used.

[Q: 635] OnExamination - Endocrinology

A 58-year-old male presents with a six month history of marked sweating. Examination reveals large hands, feet and coarse facial features. His blood pressure is 172/102 mmHg.

What is the explanation for the excessive sweating in this man?

- 1- Increased Catecholamine secretion
- 2- Increased bradykinin release
- 3- Reduced sex hormone secretion
- 4- Sweat gland hypertrophy and hyperplasia
- 5- Organomegaly with increased thermogenesis

Answer & Comments

Answer: 4- Sweat gland hypertrophy and hyperplasia

This man has features of acromegaly and the hyperhidrosis is a symptom. The mechanisms are not entirely clear and to me this is a stupid question but the RCP are full of occasional stupid questions. I suspect that the numbskull that composed such a question for the RCP had actually performed the research on this particular area!

However, as this type of question is asked, it is our duty to provide such themes. In acromegaly it appears that the increased sweating relates to sweat gland hyperplasia.

[Q: 636] OnExamination - Endocrinology

A 17 year-old female is referred following a visit to the dentist where marked erosion of her teeth was noted. She was entirely asymptomatic and her only medication was the oral contraceptive pill. On examination her blood pressure was 110/70 mmHg and her body mass index was 21.5 kg/m² (18 - 25).

Investigations

sodium 135 mmol/l

potassium 2.1 mmol/l

bicarbonate 42 mmol/l

urea 2.6 mmol/L

corrected calcium 2.08 mmol/l

alkaline phosphatase 201 iu/l (50-110)

What is the most likely diagnosis?

- 1- Bulimia nervosa
- 2- Conn's syndrome
- 3- Laxative abuse
- 4- Pregnancy
- 5- Primary hypoparathyroidism

Answer & Comments

Answer: 1- Bulimia nervosa

This patient has tooth erosion associated with hypokalaemic metabolic alkalosis and hypocalcaemia. This suggests a diagnosis of bulimia which may cause a mild hypocalcaemia. Hypoparathyroidism is a possible answer but the alkaline phosphatase would be expected to be normal/low with this condition. Again tooth erosion and the like is typical of primary hypoparathyroidism. Conn's is unlikely in this age group, is not associated with tooth erosion and hypertension would be expected. Laxative abuse would be associated with hypokalaemia but the hypocalcaemia with raised alkaline phosphatase would not be expected. Early pregnancy would not fit this picture.

[Q: 637] OnExamination - Endocrinology

A 46-year-old male presents passing 4-5 litres of urine per day, after commencing a new drug.

Serum sodium 142 mmol/l

Plasma osmolality 295 mosmol/l (275-290)

Urine osmolality 280 mosmol/l (350-1000)

What drug was prescribed?

- 1- Carbamazepine
- 2- Chlorpropamide
- 3- Fluoxetine
- 4- Furosemide

5- Lithium

Answer & Comments

Answer: 5- Lithium

The patient appears to have a drug induced Diabetes Insipidus based upon the high urine output, low urine osmolality and the high plasma osmolality. The most likely cause is Lithium. Chlorpropamide causes a SIADH as does carbamazepine and fluoxetine. Furosemide is another possibility but if it had dried the patient out the plasma sodium would be expected to be higher. It is most likely that the patient has started lithium for a psychiatric disorder. A 46-year-old male would be unlikely to be receiving high doses of furosemide.

[Q: 638] OnExamination - Endocrinology

A 45-year-old male is found to have a 2cm right adrenal adenoma which was noted co-incidentally following abdominal CT scan performed for investigation of abdominal pain. There are no abnormalities on examination and the patient is quite well with a blood pressure of 122/84 mmHg. Urine catecholamines are normal, urine free cortisol normal and plasma renin activity:aldosterone ratio is normal.

Which is the most appropriate management step for this patient?

- 1- Arrange PET scan
- 2- Arrange adrenalectomy
- 3- Characterise further with MRI
- 4- Repeat imaging in 6 months
- 5- Reassure and discharge

Answer & Comments

Answer: 4- Repeat imaging in 6 months

This appears to be an adrenal incidentaloma as evidenced by the normal endocrine

investigations. Similarly, its small size would argue against this being an adrenal carcinoma, with the cut-off for surgery being approx 4cm. However, it is important to ensure that the lesion is not growing and therefore repeat scanning in approx 6 months is required. If the tumour were enlarging then surgery may be indicated. CT is typically as good as MRI in the imaging of the adrenal, therefore one would not request a MR now as the CT imaging would be adequate.

[Q: 639] OnExamination - Endocrinology

A 17 year female presents with tingling and muscle cramps. There is no other past medical history of note. Investigations reveal

Creatinine 68 micromol/L (50-100)

calcium 1.76 mmol/L (2.2-2.6)

albumin 38 g/L (37-49)

Which one of the following investigations is most likely to confirm the diagnosis?

- 1- Alkaline phosphatase concentration
- 2- CT brain scanning
- 3- PTH concentration
- 4- Urine calcium concentration
- 5- Vitamin D concentration

Answer & Comments

Answer: 3- PTH concentration

This patient has low calcium which could be due to either Vitamin D deficiency or hypoparathyroidism. The most likely cause in a young patient who has otherwise been quite well with normal renal function would therefore be hypoparathyroidism. Urine calcium concentrations are useful in familial hypercalciuric hypercalcaemia.

[Q: 640] OnExamination -
Endocrinology

Which of the following statements are true of primary hyperparathyroidism?

- 1- It is associated with hypocalciuria due to elevated PTH levels.
- 2- PTH is secreted in a pulsatile manner from the posterior pituitary and acts through PTH receptors on parathyroid cell membranes
- 3- It is usually caused by an adenoma of a single parathyroid gland.
- 4- It progresses to tertiary hyperparathyroidism with time.
- 5- It is associated with bone resorption by PTH to restore depressed serum calcium levels to normal.

Answer & Comments

Answer: 3- It is usually caused by an adenoma of a single parathyroid gland.

"Primary HPT can be divided pathologically into adenoma, hyperplasia, and carcinoma. Adenomas clearly are the most prevalent entity representing 80-85% of cases. Hyperplasia is the second most common diagnosis constituting 15% of cases. Carcinoma represents <1% of total cases. Double adenoma has been found in approximately 5% of the time, and complicates the clinical distinction between adenoma and hyperplasia. Histologically, normal parathyroid tissue shows a cell to fat ratio of 1:1. Hypercellular parathyroid tissue is typified by the loss of the normal amount of fat."

In primary hyperparathyroidism there is usually hypercalciuria. Secondary hyperparathyroidism may progress to tertiary but primary does not.

[Q: 641] OnExamination -
Endocrinology

Which of the following is typically found in Pendred's syndrome

- 1- Mental retardation
- 2- Sensorineural deafness
- 3- Thyroid agenesis
- 4- Thyrotoxicosis
- 5- Cataract

Answer & Comments

Answer: 2- Sensorineural deafness

Pendred's syndrome is an autosomal recessive condition which includes nerve deafness with goitre due to a defect of iodine binding. Patients are usually euthyroid.

[Q: 642] OnExamination -
Endocrinology

A 16-year-old male with a day history of malaise, weakness and vomiting. He was diagnosed with Insulin dependent diabetes mellitus 3 years previously.

Which ONE of the following supports a diagnosis of diabetic ketoacidosis:

- 1- Abdominal pain at onset
- 2- A serum standard bicarbonate of 10 mmol/l (NR 22-26)
- 3- A random serum glucose 14 mmol/l (NR 4.5-6-4)
- 4- Decreased appetite in the past few days
- 5- Shallow respirations

Answer & Comments

Answer: 2- A serum standard bicarbonate of 10 mmol/l (NR 22-26)

1-An unusual but recognised feature particularly in children. However does not support a diagnosis of DKA. 2-The low plasma bicarbonate is highly suggestive of a metabolic

acidosis. 3-'Normoglycaemic DKA' can occur and a glucose of 14 is compatible with a diagnosis but is not suggestive as one might expect to find these sort of concentrations with diabetes per se. 4-Usually patients are unwell with infections and anorexia. Fasting is itself associated with the presence of ketones in the urine but not necessarily ketoacidosis. 5-Respiratory compensation leads to rapid deep (Kussmaul's) breathing.

[Q: 643] OnExamination - Endocrinology

A 28-year-old female presents in the 24th week of pregnancy with profound tiredness and anxiety. Examination reveals a tremor, a pulse of 100 beats per minute and a soft bruit heard over the thyroid gland.

Thyroid function tests show:

Free T₄ 32.9 pmol/l (NR 9.8 - 23.1)

TSH 0.04 mu/l (NR 0.5 - 4)

Which of the following treatments would you select for this patient?

- 1- Radioactive iodine therapy
- 2- Carbimazole
- 3- Lithium
- 4- Propranolol
- 5- Potassium perchlorate

Answer & Comments

Answer: 2- Carbimazole

This patient has Graves' disease and the most appropriate treatment for the thyrotoxicosis is carbimazole. This she should receive in the lowest dose to maintain euthyroidism. A block and replacement regime is not appropriate in pregnancy. Radioactive iodine is contra-indicated as it would also be taken up by the foetal thyroid. Propranolol would ameliorate the symptoms but may impact upon the fetus. Lithium is contra-indicated in pregnancy as is

potassium perchlorate. Of course surgery may also be used in severe cases.

Both carbimazole and propylthiouracil may (and should) be used in pregnancy. Many prefer propylthiouracil because there is some evidence that it may be less likely to be transferred across the placenta.

[Q: 644] OnExamination - Endocrinology

A 26-year-old man with a past history of parathyroid surgery presented with galactorrhoea.

Investigations:

plasma follicle-stimulating hormone 4.2 U/L (1-7)

plasma luteinising hormone 5.6 U/L (1-10)

plasma prolactin 1654 mU/L (<360)

plasma thyroid-stimulating hormone 3.8 mU/L (0.4-5)

insulin-like growth factor 1 33.4 nmol/L (7.5-37.3)

Which of the following is the most likely diagnosis?

- 1- MEN type 1
- 2- MEN type 2a
- 3- MEN type 2b
- 4- Polyglandular syndrome type 1
- 5- Polyglandular syndrome type 2

Answer & Comments

Answer: 1- MEN type 1

The story of galactorrhoea suggests hyperprolactinaemia and in the context of primary hyperparathyroidism suggests MEN type 1. MEN type 1 is an autosomal dominant condition and is associated with hyperparathyroidism, pancreatic neuroendocrine tumours and pituitary tumours.

[Q: 645] OnExamination -
Endocrinology

A 55-year-old female presents with episodic sweats and tremors which are relieved by glucose. She has gained approximately 6 kg in weight of late and drinks approximately 10 units of alcohol weekly.

Her investigations show normal Full Blood Count, Normal Urea and electrolytes and a fasting plasma glucose concentration of 4 mmol/l (3-6).

What is the most appropriate investigation for this patient?

- 1- 72 hour fast
- 2- CT scan of pancreas
- 3- EEG
- 4- Insulin and C-peptide concentration
- 5- Oral glucose tolerance test

Answer & Comments

Answer: 1- 72 hour fast

This patient describes symptoms suggestive of hypoglycaemia which are relieved by carbohydrate. The likely cause is an insulinoma which is producing the weight gain.

The standard method for achieving a diagnosis is during a 72 hour fast by demonstration of inappropriately high insulin and C peptide during spontaneous hypoglycaemia.

Measurement of C-peptide is useful for excluding factitious hypoglycaemia from self injection of insulin. Insulin preparations contain no C-peptide.

[Q: 646] OnExamination -
Endocrinology

Which of the following is a feature of Cushing's syndrome?

- 1- Fibrous dysplasia

- 2- Vertebral collapse
- 3- Calcium pyrophosphate arthropathy
- 4- Osteomalacia
- 5- Osteoarthritis

Answer & Comments

Answer: 2- Vertebral collapse

Vertebral collapse may be due to osteoporosis. Osteoarthritis and gout would be unusual with elevated corticosteroid concentrations. Osteomalacia is not a feature.

[Q: 647] OnExamination -
Endocrinology

An 17-year-old female presented with a one year history of secondary amenorrhoea. She had been prescribed Temazepam and Dihydrocodeine previously.

On examination she had galactorrhoea to expression. Her prolactin concentration was 6000 mu/l (NR 50-450). Pregnancy test was negative.

What is the most likely diagnosis?

- 1- Drug-induced hyperprolactinaemia
- 2- Non functioning pituitary tumour
- 3- Pituitary microadenoma
- 4- Polycystic ovarian syndrome
- 5- Turner's syndrome

Answer & Comments

Answer: 3- Pituitary microadenoma

The history and examination findings together with the grossly elevated prolactin concentration are suggestive of a microprolactinoma. This is not Polycystic Ovarian Syndrome as the hyperprolactinaemia is far too high. The drugs that she is taking would not cause hyperprolactinaemia as agents such as dopamine antagonists, antipsychotic agents and tricyclic

antidepressants may be responsible. If she were to have a non-functioning pituitary tumour, stalk c

[Q: 648] OnExamination - Endocrinology

A 16-year-old female with Addison's disease is intolerant of her hydrocortisone treatment which she takes at a dose of 20mg in the morning and 10mg in the evening.

Which of the following doses of prednisolone would provide an equivalent daily dose as her hydrocortisone?

- 1- 5mg
- 2- 7.5mg
- 3- 10mg
- 4- 12.5mg
- 5- 15mg

Answer & Comments

Answer: 2- 7.5mg

The equivalent ratio of prednisolone to hydrocortisone is approximately 1:4. For Dexamethasone to Hydrocortisone the ratio is roughly 1:24.

[Q: 649] OnExamination - Endocrinology

A diagnosis of diabetes mellitus is being considered in 32-year-old woman who is 16 weeks pregnant. Her body mass index (BMI) was 22 kg/m² (18 - 25). A 75g oral glucose tolerance test was reported as follows

Time	Plasma glucose concentration	Normal range
0 hr	6.0 mmol/l	3.0-6.0
2hr	12.5 mmol/l	<11.1

Which of the following is the most appropriate next step in the management of this patient?

- 1- Glipizide therapy

- 2- Insulin therapy
- 3- Low calorie diet
- 4- Metformin therapy
- 5- Repeat OGTT in four weeks

Answer & Comments

Answer: 2- Insulin therapy

The result confirms a diagnosis of gestational diabetes mellitus with the 2hr OGTT result above 11.1 mmol/l. To minimise the fetal consequences of GDM (macrosomia, fetal malformations, still birth, IUGR etc), the patient's glycaemia should be strictly controlled with insulin. A low calorie diet is inappropriate and neither metformin nor glipizide are licenced for use in pregnancy. There is no point in repeating the OGTT in 4 weeks as control is required NOW.

[Q: 650] OnExamination - Endocrinology

A 16-year-old female presents with hypertension and increasing weight.

Which of the following features would be most suggestive of Cushing's syndrome rather than simple obesity?

- 1- Abdominal striae
- 2- Acanthosis Nigricans
- 3- Buffalo Hump (interscapular fat pad)
- 4- Moon face
- 5- Proximal myopathy

Answer & Comments

Answer: 5- Proximal myopathy

Proximal myopathy, easy bruising and thin skin are clinical features that are most suggestive of Cushing's syndrome. Otherwise, abdominal striae, buffalo hump, and acanthosis nigricans are all features of obesity. Similarly Oligomenorrhoea would be a feature of obesity/polycystic ovarian syndrome.

[Q: 651] OnExamination -
Endocrinology

A 45-year-old woman presents with excessive hair growth on her face, chest and lower abdomen.

Which of the following may be associated with her condition?

- 1- Cyproterone
- 2- Hypoadrenalism
- 3- Minoxidil
- 4- Moxonidine
- 5- Valproate

Answer & Comments

Answer: 3- Minoxidil

Drugs causing hirsutism/hypertrichosis include minoxidil (not moxonidine - a centrally acting anti-hypertensive), phenytoin (not valproate) and cyclosporin. Polycystic ovaries and congenital adrenal hyperplasia are associated with increased androgens and hirsutism; hypoadrenalism may be associated with loss of hair ?especially pubic hair. Treatment of hirsutism is with anti-androgens (cyproterone, spironolactone), reduction of free androgens (oestrogen therapy, OCP, weight loss), and cosmetic treatment for removal of hair.

[Q: 652] OnExamination -
Endocrinology

A previously fit 30-year-old male presents with a two months history of weight loss, tiredness and nausea.

Investigations show:

Haemoglobin 10.5 g/dL
MCV 88 fL
White cell count $6.0 \times 10^9/L$
Platelets $450 \times 10^9/L$
Serum sodium 130 mmol/L

Serum potassium 5.7 mmol/L
Serum urea 3.0 mmol/L
Serum creatinine 78 $\mu\text{mol/L}$
Serum total T_4 55 nmol/L (NR 50-150)
Serum TSH 8 mU/L (NR 0.2-5.5)

Which of the following is the most useful diagnostic investigation?

- 1- anti-thyroid peroxidase antibody titre
- 2- insulin tolerance test
- 3- free thyroxine concentration
- 4- short synacthen test
- 5- TRH test

Answer & Comments

Answer: 4- short synacthen test

This patient presents with weight loss, tiredness and nausea. He has hyponatraemia, hyperkalaemia and what appears to be a mild primary hypothyroidism. The diagnosis is likely to be Addison's (primary hypoadrenalism) disease and the most appropriate test would be a short synacthen test.

The link between Addison's and primary hypothyroidism is that they are both conditions in the complex of autoimmune polyendocrine syndrome. Other possible associations of this cluster would be Type 1 Diabetes, vitiligo, pernicious anaemia and chronic active hepatitis.

An insulin tolerance test is contra-indicated in patient's in whom cortisol is less than 100 nmol/L. A TRH test is rarely performed these days and really is an irrelevance.

[Q: 653] OnExamination -
Endocrinology

A 26-year-old woman presents with episodes of dizziness mainly on standing. Her biochemical profile shows hyperkalaemic acidosis.

Which underlying condition is she most likely to have?

- 1- Cushing's syndrome
- 2- Addison's disease
- 3- Conn's syndrome
- 4- Type 1 renal tubular acidosis
- 5- Bulimia nervosa

Answer & Comments

Answer: 2- Addison's disease

Her symptoms are suggestive of postural hypotension, which together with hyperkalaemic (and hyponatraemia) acidosis would strongly indicate the presence of Addison's disease. Cushing's and Conn's syndromes are associated with hypertension and hypokalaemia. Hypokalaemia is the most frequent complication of bulimia which may cause cardiac arrhythmias, fits and paraesthesia. Renal tubular acidosis (RTA) is due to inability of the renal tubules to maintain acid-base balance, causing a hyperchloraemia and a normal anion-gap. In type 1 (distal) RTA, there is hypokalaemic acidosis with low urinary ammonium production. Patients present with hyperventilation/acidosis and muscular weakness from hypokalaemia. In type 4 RTA (hyporeninaemic hypoaldosteronism), there is hyperkalaemic acidosis caused by chronic renal insufficiency from diabetes or tubulointerstitial disease.

[Q: 654] OnExamination - Endocrinology

A 15-year-old girl was admitted eight hours after taking an overdose of Diazepam 30mg and Methotrexate 400mg, which her mother had been prescribed for rheumatoid arthritis. On examination her Glasgow Coma Score was 10.

Which one of the following is the most appropriate immediate action?

- 1- Assess respiratory function
- 2- Perform immediate gastric lavage
- 3- Treat with activated charcoal
- 4- Treat with folic Acid
- 5- Urgent liver function tests

Answer & Comments

Answer: 1- Assess respiratory function

Her depressed GCS is due to the diazepam and the most appropriate initial treatment would be to assess her respiratory function prior to giving her folic acid.

Methotrexate overdose is extremely rare but potentially fatal with hepatotoxicity and renal toxicity reported. The most appropriate treatment is folic acid (Leucovorin). It is too late to consider gastric lavage or activated Charcoal.

[Q: 655] OnExamination - Endocrinology

A 54-year-old female presented with a neck swelling which has been more noticeable over the previous four months.

Examination revealed a moderate goitre and clinically she appeared euthyroid.

Investigations revealed:

T₄ 13.1 pmol/l (NR 9.8 - 23)
TSH 5.3 mU/l (NR 0.5 - 4 mU/l)

anti -microsomal antibodies positive

What is the most likely explanation of this patient's goitre?

- 1- Graves' disease
- 2- Hashimoto's thyroiditis
- 3- DeQuervain's thyroiditis
- 4- Multi-nodular goitre
- 5- Anaplastic thyroid carcinoma

Answer & Comments

Answer: 2- Hashimoto's thyroiditis

This patient has goitre with subclinical hypothyroidism, as reflected by elevated TSH but normal T4 and elevated microsomal antibodies. This suggests a diagnosis of Hashimoto's thyroiditis.

[Q: 656] OnExamination -
Endocrinology

A 48-year-old woman presents to her GP with Cushingoid facies and hyperpigmentation of the skin on her face and chest. She has smoked 20 cigarettes per year for 30 years. Examination reveals no gross abnormalities. Her chest X-ray reveals a 2 cm irregularly shaped mass in the right upper lobe, in proximity to the mediastinum. A CT guided needle biopsy of the lung lesion is performed.

Which would be the most likely cytologic finding?

- 1- Adenocarcinoma
- 2- Benign bronchial adenoma
- 3- Bronchoalveolar cell carcinoma (BAC)
- 4- Small cell (oat cell) carcinoma
- 5- Squamous cell carcinoma

Answer & Comments

Answer: 4- Small cell (oat cell) carcinoma

This patient has typical features of ectopic ACTH secretion which is usually due to a small cell lung cancer. Other less common causes of ectopic ACTH secretion include bronchial Carcinoids.

[Q: 657] OnExamination -
Endocrinology

A 45-year-old woman presents to the clinic with a three month history of sweats and weight gain of 7kg. Her sweats tend to be worse in the morning and with exercise and

she often feels light headed. On examination she has a BMI of 30 kg/m² but no abnormality is noted. Urinalysis negative.

What is the likely diagnosis?

- 1- Acromegaly
- 2- Diabetes mellitus
- 3- Insulinoma
- 4- Pheochromocytoma
- 5- Primary ovarian failure

Answer & Comments

Answer: 3- Insulinoma

This patient has sweats and weight gain exacerbated by exercise or fasting (a.m.) and associated with lightheadedness. This information suggests the presence of an insulinoma. Pheochromocytoma is unlikely as there is typically weight loss and there is no mention of hypertension. Acromegaly - features should be described. Diabetes Mellitus per se, possibly urinalysis would be expected to show glycosuria.

Presenting features of insulinoma include double vision, tachycardia / palpitations, "weakness", confusion, memory loss, seizures, sweating, hunger and weight gain.

[Q: 658] OnExamination -
Endocrinology

Following factors decrease large intestinal motility:

- 1- Parasympathetic activity
- 2- Anticholinergic agents
- 3- Gastric Distension
- 4- CCK-PZ
- 5- Laxatives.

Answer & Comments

Answer: 2- Anticholinergic agents

The others and cholinergic agents increase large intestinal motility.

[Q: 659] OnExamination - Endocrinology

A 47-year-old male presents with marked shortness of breath which has deteriorated over the last two weeks. On examination he has a hard, irregular thyroid mass and has some difficulty breathing. There appears to be no retrosternal extension and he appears clinically euthyroid.

What is the most likely diagnosis?

- 1- Anaplastic carcinoma of thyroid
- 2- Bleed into a thyroid nodule
- 3- Follicular thyroid carcinoma
- 4- Medullary thyroid carcinoma
- 5- Multinodular goitre

Answer & Comments

Answer: 1- Anaplastic carcinoma of thyroid

This patient is likely to have anaplastic carcinoma of the thyroid with compression/infiltration of the trachea. This is unlikely to be a multinodular goitre as this would be unlikely to compress the trachea unless retrosternal and the description is more compatible with a thyroid malignancy. Medullary thyroid cancer is associated most often with MEN II and would be particularly unusual. Again follicular would be unlikely to produce such marked infiltrative features in such a short period of time. Typically patients with follicular disease would present with a nodule and/or LAP.

[Q: 660] OnExamination - Endocrinology

An 80 year-old woman with type 2 diabetes mellitus is referred with weakness. She had been taking bendroflumethiazide, digoxin and tolbutamide. On examination she had a

temperature of 37.8C, a pulse of 98 bpm in atrial fibrillation, and a blood pressure of 118/72 mmHg.

Investigations show:

Sodium	121 mmol/L (137 - 144)
Potassium	3.3 mmol/L (3.5 - 4.9)
Urea	4.8 mmol/L (2.5-7.5)
Creatinine	83 micromol/L (60 - 110)
Glucose	15.2 mmol/L (3.0 - 6.0)
chest X-ray	normal

What is the most likely cause for the hyponatraemia?

- 1- Addison's disease
- 2- bendroflumethiazide (bendroflumethiazide)
- 3- hyperglycaemia
- 4- syndrome of inappropriate secretion of antidiuretic hormone
- 5- tolbutamide

Answer & Comments

Answer: 2- bendroflumethiazide (bendroflumethiazide)

This patient has hyponatraemia and hypokalaemia. This is probably due to the bendroflumethiazide which should be stopped. It is unlikely to be SIADH, of which tolbutamide is a cause, as the hypokalaemia is not typically associated.

Her hyperglycaemia with an osmotic diuresis would cause dehydration. Addison's disease would be associated with hyperkalaemia, hypotension and elevated urea.

[Q: 661] OnExamination - Endocrinology

A 45-year-old male presents with sweats and change in appearance. A diagnosis of acromegaly is confirmed with failure to suppress GH concentrations on an oral glucose

tolerance test. MRI reveals a 0.5 cm microadenoma of the pituitary.

Which of the following is the most appropriate therapeutic option for this patient?

- 1- Dopamine agonist therapy
- 2- Depot somatostatin analogue
- 3- Pituitary surgery
- 4- Short acting somatostatin analogue
- 5- Stereotactic pituitary irradiation

Answer & Comments

Answer: 3- Pituitary surgery

Surgery is the most appropriate primary therapy for acromegaly with a cure rate of above 80% expected for a tumours of this size. Although somatostatin analogues are very effective at suppressing GH concentrations to what would be regarded as a 'cure' range (GH less than 5 $\mu\text{U/L}$ on day profile) their expense limits use on the longer term basis. However, in patients unsuitable for surgery or in those not cured following surgery SMS would be employed.

[Q: 662] OnExamination - Endocrinology

In active acromegaly with associated diabetes mellitus which of the following findings would be expected?

- 1- Diabetes mellitus is due to an auto-immune process
- 2- Growth hormone concentrations are suppressed with hyperglycaemia
- 3- IGF-1 concentrations are low
- 4- There is insulin resistance
- 5- Treatment with a somatostatin analogue is contra-indicated

Answer & Comments

Answer: 4- There is insulin resistance

Insulin resistance stems from the excessive growth hormone concentrations (anti-insulin effects) that of course fail to suppress with hyperglycaemia. Acromegaly is often effectively treated with somatostatin analogues which may improve glycaemic control. Many of the effects of GH are mediated through IGF-1 whose concentrations are high in acromegaly. Diabetes mellitus is due to the insulin resistance and is not due to auto-immune insulinitis.

[Q: 663] OnExamination - Endocrinology

A 60-year-old female was prescribed thyroxine 150 μg daily for hypothyroidism. She was clinically hypothyroid and no goitre was present.

Investigations revealed:

serum total T_4 68 nmol/L (NR 55-145)

serum total T_3 0.5 nmol/L (NR 0.9-2.5)

serum TSH 70 mU/L (NR 0.5-4)

Which of the following would be the next step in her management?

- 1- Investigation for TSH secreting pituitary tumour
- 2- Measurement of free thyroxine concentration
- 3- Questioning of the patient about compliance
- 4- She has sick euthyroid syndrome, no further investigation required
- 5- Thyroid ultrasound scan

Answer & Comments

Answer: 3- Questioning of the patient about compliance

No one measures total Thyroid hormone levels any more except the RCP. Pathetic! This patient has a raised TSH but normal total thyroxine and a low T_3 . Either there is a block on the conversion of T_4 to T_3 or as seems

more likely the patient has just taken the T4 prior to coming to clinic. The explanation is non-compliance.

[Q: 664] OnExamination - Endocrinology

A 16-year-old female weighing 80kg presents with a six month history of excessive weight gain and weakness. On examination she had central obesity with abdominal striae, a blood pressure of 178/96 mmHg and proximal muscle weakness. Urinalysis showed glucose ++.

What is the most appropriate initial investigation for this patient?

- 1- 9am plasma cortisol concentration
- 2- 24 hour urinary free cortisol concentration
- 3- ACTH concentration
- 4- a 1mg overnight dexamethasone suppression test
- 5- a short synacthen test

Answer & Comments

Answer: 2- 24 hour urinary free cortisol concentration

This patient is likely to have Cushing's syndrome. It's a difficult choice between overnight dexamethasone suppression test and the urine free cortisol estimation but on balance, the simplest test would be Urine free cortisol assessment. In the dexamethasone suppression test 25-30 micrograms/kg is used (max 2mg), so the amount suggested in this question is too small. 9am cortisol and ACTH concentrations will not confirm the diagnosis. A short synacthen test is used to confirm hypoadrenalism.

[Q: 665] OnExamination - Endocrinology

A 30 year-old female presents with a one year history of galactorrhoea. She has been

receiving treatment for hay fever, depression, obesity and dyspepsia. Her investigations reveal:

Full Blood Count	normal
Urea and electrolytes	normal
Prolactin	820 mU/L (< 360)
free thyroxine (T ₄)	18.3 pmol/L (10-22)
TSH concentration	2.1 mU/L (0.4 - 5)

Which one of the following drugs is most likely to explain these findings?

- 1- Astemizole
- 2- Metoclopramide
- 3- Paroxetine
- 4- Ranitidine
- 5- Sibutramine

Answer & Comments

Answer: 2- Metoclopramide

Although the SSRIs are also rarely associated with hyperprolactinaemia, the answer has to be Metoclopramide which is a dopamine antagonist that is typically associated with hyperprolactinaemia.

[Q: 666] OnExamination - Endocrinology

A 45-year-old female attends clinic complaining of tiredness. She is hypothyroid and takes thyroxine 150 micrograms daily.

Which of the following is the most useful test for assessing the appropriateness of thyroid hormone replacement in primary hypothyroidism?

- 1- Free T3 and T4 concentrations
- 2- Skin biopsy
- 3- Thyroid binding globulin
- 4- Total T3 and T4
- 5- TSH

Answer & Comments

Answer: 5- TSH

TSH has been recognized as an exquisitely sensitive indicator of thyroid status. A normal TSH result suggests adequate thyroid hormone replacement and euthyroidism. Similarly elevated TSH with normal thyroid hormone concentrations would suggest poor compliance and suppressed TSH with normal - high T4 suggests over-replacement.

[Q: 667] OnExamination - Endocrinology

Which one of the following types of thyroid cancer in a 45-year-old woman has the worst prognosis following optimal treatment?

- 1- Papillary cancer with cervical lymph node metastases
- 2- Follicular cancer with bone metastases
- 3- Anaplastic cancer in a long standing goitre
- 4- Medullary cancer as part of the MEN type II syndrome
- 5- Thyroid lymphoma

Answer & Comments

Answer: 3- Anaplastic cancer in a long standing goitre

Anaplastic carcinoma usually occurs in middle-aged and older patients with longstanding goitre. The gland may suddenly increase in size producing pressure symptoms, dysphagia or vocal cord paralysis. The tumour is resistant to therapy. Death from massive local extension usually occurs within 3-36 months. Thyroid Medullary carcinoma is the next most aggressive, especially so in MEN 2B subjects, but less so in 2A subjects. Lymphoma may respond dramatically to irradiation.

[Q: 668] OnExamination - Endocrinology

A 16-year-old female patient is referred with

primary amenorrhoea. Investigations reveal a 46 XY karyotype.

Which of the following concerning the condition is true?

- 1- A diagnosis of Turner's syndrome is likely
- 2- It is likely that her mother received Carbimazole for thyrotoxicosis during pregnancy
- 3- Low testosterone and oestradiol concentrations would be expected
- 4- The diagnosis is likely to be testicular feminisation syndrome
- 5- The diagnosis is Noonan's syndrome

Answer & Comments

Answer: 4- The diagnosis is likely to be testicular feminisation syndrome

A female phenotype can occur in testicular feminisation, a condition associated with androgen insensitivity due to an androgen receptor defect. Stilboestrel therapy has been associated with the induction of latent tumours and to influence sexual behaviour but is not associated with abnormalities of sexual identity. In Noonan's syndrome, infants are males but physical features resemble that found in Turner's syndrome. Neither prednisolone nor maternal thyrotoxicosis would cause gender mal-assignment problems.

[Q: 669] OnExamination - Endocrinology

A 60-year-old female presents with recent-onset dyspnoea and noisy breathing. Her chest X-ray showed right deviation of the trachea due to a retrosternal goitre.

Which of the following tests is most useful in the assessment of airflow obstruction due to the goitre?

- 1- flow volume curve

- 2- forced expiratory flow volume in one second
- 3- forced vital capacity
- 4- peak expiratory flow rate
- 5- residual volume

Answer & Comments

Answer: 1- flow volume curve

Inspection of the maximal expiratory and inspiratory flow-volume curve is currently the simplest method to establish the presence of upper airway obstruction associated with a retrosternal goitre. This may be present in up to 40% of patients with retrosternal goitre and generally requires at least 50% obstruction of the airway before symptoms arise.

[Q: 670] OnExamination - Endocrinology

An 16-year-old man presents with polyuria and polydipsia.

Which of the following may confirm the diagnosis of diabetes mellitus?

- 1- A random plasma glucose of >7.5 mmol/L
- 2- A finding of 3+ ketonuria
- 3- An HbA1c of 7.0%
- 4- A fasting plasma glucose of 7.5 mmol/L
- 5- A plasma glucose of 10.2 mmol/l 2 hours after 75 grams of oral glucose.

Answer & Comments

Answer: 4- A fasting plasma glucose of 7.5 mmol/L

The diagnosis is usually relatively easy to confirm in a symptomatic subject. A random glucose of >11.1 mmol/L or a fasting glucose of >7.0 mmol/L would be regarded as confirmatory. There is usually glycosuria in addition to ketonuria. Isolated ketonuria suggests fasting. A raised glycosolated haemoglobin (HbA1c) is also highly suggestive

but not diagnostic. A glucose tolerance test is rarely needed.

[Q: 671] OnExamination - Endocrinology

A 32-year-old female is being investigated for tinnitus by the ENT department and undergoes an MRI scan. The scan is normal except for a pituitary tumour of 0.9cm confined to the pituitary fossa. Thyroid function tests, prolactin, LH, FSH and estradiol concentrations are all normal.

Which of the following would be the most appropriate management approach for this patient?

- 1- Pituitary biopsy
- 2- Reassure and continued observation
- 3- Transphenoidal hypophysectomy
- 4- Treat with dopamine agonist therapy
- 5- Stereotactic pituitary irradiation

Answer & Comments

Answer: 2- Reassure and continued observation

This patient has a co-incidentally noted pituitary tumour, has no endocrine symptoms and appears to have normal endocrine function although we are not provided with information pertaining to cortisol secretory function nor GH. With this caveat in mind, the most appropriate strategy would be observation and repeat scanning.

[Q: 672] OnExamination - Endocrinology

A 53-year-old male is suspected of having acromegaly.

Which of the following is the best investigation to confirm the diagnosis?

- 1- 9am growth hormone concentrations

- 2- An insulin tolerance test with growth hormone concentrations
- 3- Glucose tolerance test with growth hormone concentrations
- 4- Growth hormone releasing hormone test
- 5- insulin-like growth factor-1 (IGF-1)

Answer & Comments

Answer: 3- Glucose tolerance test with growth hormone concentrations

The diagnosis of Acromegaly is confirmed by inadequate suppression of GH concentrations below 2 mU/l in an oral glucose tolerance test. Although IGF-1 concentrations are elevated these are not diagnostic and may fall during illness.

[Q: 673] OnExamination - Endocrinology

Which of the following is associated with Congenital Adrenal Hyperplasia?

- 1- Delayed puberty
- 2- Hypopigmentation
- 3- Hyporeninaemia
- 4- Persistent Wolffian duct
- 5- Premature epiphyseal closure

Answer & Comments

Answer: 5- Premature epiphyseal closure

Premature epiphyseal closure is a classical feature of CAH, and is secondary to high levels of sex steroids. Under, and over treatment of CAH patients puts patients at risk of short stature, over treatment because of the glucocorticoid induced inhibition of the growth axis. CAH is associated with precocious puberty caused by long term exposure to androgens, which activate the hypothalamic-pituitary-gonadal axis.

Similarly, CAH is associated with hyperpigmentation, and hyperreninaemia due

to sodium loss and hypovolaemia. The Wolffian duct is never formed in CAH.

[Q: 674] OnExamination - Endocrinology

A 16-year-old girl is noted to have persistent polyuria in excess of 4 litres per day whilst recovering from a head injury she sustained in a road traffic accident. Investigations reveal:

potassium 4.1 mmol/L (3.5-4.9)
calcium 2.4 mmol/L (2.2-2.6)
glucose 5.6 mmol/L (3.0-6.0)

Which one of the following is the most effective method of confirming the diagnosis?

- 1- autoantibodies to vasopressin neurones
- 2- MRI of the hypothalamus and pituitary
- 3- therapeutic trial of low dose DDAVP
- 4- vasopressin concentration
- 5- water deprivation test

Answer & Comments

Answer: 5- water deprivation test

The history and confirmed polyuria are suspicious of diabetes insipidus which is not uncommon after head injury. This can be confirmed with a water deprivation test where failure of urine concentration would be expected. A MRI of the pituitary and hypothalamus may show no abnormality but would be undertaken after the diagnosis of DI is confirmed. Similarly anterior hormone assessment would also be undertaken after the diagnosis is confirmed. A therapeutic trial of DDAVP is only appropriate if the diagnosis of DI is confirmed as primary polydipsia can also be a feature of trauma and in these circumstances DDAVP may precipitate hyponatraemia. Autoantibodies to ADH neurones are irrelevant.

[Q: 675] OnExamination -
Endocrinology

A 45-year-old woman presents with a 1 year history of weight gain and intermittent sweating.

What is the most likely diagnosis?

- 1- Carcinoid syndrome
- 2- Hypothyroidism
- 3- Insulinoma
- 4- Lymphoma
- 5- Pheochromocytoma

Answer & Comments

Answer: 3- Insulinoma

The clinical scenario is classic of insulinoma. Weight gain is the key differentiating feature here - sweating being more commonly shared with the other conditions except hypothyroidism. There is nothing else offered, other than insulinoma, that explain both symptoms in this middle aged woman.

As primary ovarian failure is not offered which would seem the most probable answer then the features would otherwise suggest an insulinoma which is commoner in females and unlike carcinoid and lymphoma is associated with weight gain rather than weight loss. Pheochromocytoma is associated with bouts of sweating but not weight gain - there is also no mention of other typical features such as palpitations and hypertension.

[Q: 676] OnExamination -
Endocrinology

A 17-year-old boy has learning difficulties and is seen in the genetics clinic as his maternal uncles also had learning difficulties. Examination reveals that the patient has large ears and large testes.

What is the most likely genetic diagnosis?

- 1- 47 XYY

- 2- Acromegaly
- 3- Fragile X syndrome
- 4- Klinefelter's syndrome
- 5- Mosaic Down's syndrome

Answer & Comments

Answer: 3- Fragile X syndrome

In addition to moderate to severe mental retardation, other characteristics of individuals with Fragile X syndrome may include large ears, macroorchidism, prognathism, speech delays, prominent forehead, double-jointedness, autistic symptoms and occasional self-mutilation. The face is typically long and narrow, with a high arched palate and large ears.

Otitis media, strabismus, and dental problems may be present. Other common characteristics include hyperextensible joints, hypotonia, and heart problems including mitral valve prolapse.

In males, abnormally large testes are a distinctive feature. In young children, delayed motor development, hyperactivity, behavioural problems, toe walking, and occasional seizures can occur.

[Q: 677] OnExamination -
Endocrinology

A 30-year-old man had a blood pressure of 150/100 mmHg. Clinical examination was normal.

Which one of the following would suggest secondary hypertension?

- 1- 24 hour urinary protein excretion of 1.6g (<0.2)
- 2- A Creatinine clearance of 90 mL/min (70-140)
- 3- Left ventricular hypertrophy criteria on the ECG

- 4- The presence of arteriovenous nipping on fundoscopy.
- 5- Serum potassium of 3.9 mmol/L (3.5-4.9)

Answer & Comments

Answer: 1- 24 hour urinary protein excretion of 1.6g (<0.2)

It is rather young for a 30-year-old to be hypertensive but the presence of such a nephrotic range of urine protein would suggest renal origin ?Polyarteritis nodosa etc. The potassium concentration is normal and although it does not exclude Conn's it is certainly not suggestive. LVH would be found with sustained hypertension of any aetiology as would av nipping. The creatinine clearance is normal.

[Q: 678] OnExamination - Endocrinology

In the treatment of Congenital Adrenal Hyperplasia, which of the following statements is correct?

- 1- Hydrocortisone may be administered once daily
- 2- Preferred treatment in children is prednisone
- 3- Efficacy of treatment is best monitored by 17-OH progesterone and androstenedione levels
- 4- Renin activity levels are of no clinical use in treatment monitoring
- 5- Hypotension, hyperkalaemia and hyperreninaemia suggest that the dose of mineralocorticoid should be reduced

Answer & Comments

Answer: 3- Efficacy of treatment is best monitored by 17-OH progesterone and androstenedione levels

In the treatment of CAH the lowest dose of glucocorticoid that suppresses(not totally)

Adrenal androgens, whilst maintaining normal growth and weight gain is the optimum dose of glucocorticoid replacement.

Renin activity levels can be used to monitor adequacy of mineralocorticoid and sodium replacement. Hydrocortisone has a relatively short half-life and must therefore be administered twice daily, whilst the preferred mode of glucocorticoid replacement in children is hydrocortisone as it minimises growth suppression.

Over treatment with mineralocorticoids leads to hypertension, suppressed plasma rennin activity and possibly growth retardation.

[Q: 679] OnExamination - Endocrinology

A 17-year-old girl complains of feeling tired and lethargic for the last 6 months. She also has generalized abdominal discomfort and constipation. She denies depression but her performance at school has deteriorated this year. Examination shows a pale and thin young woman. Her blood pressure is 110/60 mmHg.

Hb 13.4 g/l
 WBC 4.8×10^9
 Platelet 290×10^9
 ESR 37mm/hr
 Na 131mM (135-144)
 K 2.7mM (3.4-4.5)
 Urea 3.0mM (3-7)
 Creat 90mM (50 - 100)
 Bicarbonate 35mM (20-28)
 Alkaline phosphatase 90iu/l (50-110)
 Bilirubin 12 (0-17)
 AST 30 iu/l (5-40)
 Albumin 36 g/l (33-44)
 CXR normal

Which of the following is the most likely underlying diagnosis?

- 1- Cushings syndrome
- 2- Conns syndrome
- 3- Addisons disease
- 4- Anorexia nervosa
- 5- Pheochromocytoma

Answer & Comments

Answer: 4- Anorexia nervosa

This patient has anorexia nervosa with self-induced vomiting, which would explain the low Na, K and alkalosis. Addisons disease causes hyponatraemia and hyperkalaemic acidosis, whilst Cushings disease cause hypokalaemic alkalosis. The clinical presentation does not fit with the latter. Conn's syndrome (adrenal adenoma) is associated with hypertension and hypokalaemia.

[Q: 680] OnExamination - Endocrinology

A 79-year-old female suffers a fracture neck of femur following a fall at home. Investigations are normal but her X-ray shows the bones to be rather 'thin'. It is assumed that she is osteoporotic and she is started on alendronate therapy.

Which of the following is correct concerning this drug.

- 1- Enhances vitamin D action on bone
- 2- Increases absorption of calcium
- 3- Increases osteoblast activity
- 4- Increases the action of oestrogen on bone
- 5- Inhibits osteoclast activity

Answer & Comments

Answer: 5- Inhibits osteoclast activity

The bisphosphonates of which alendronate is one, increase Bone mineralisation by inhibiting osteoclastic activity. They have been demonstrated in numerous studies to reduce subsequent risk of fracture.

[Q: 681] OnExamination - Endocrinology

A 39-year-old female presents with polyuria and is passing 4 litres of urine per day. She was recently started on a new medication

Serum sodium 144 mmol/l

Plasma osmolality 299 mosmol/l (275-290)

Urine osmolality 210 mosmol/l (350-1000)

Which of the following drugs was prescribed?

- 1- Aspirin
- 2- Fluoxetine
- 3- Glibenclamide
- 4- Lithium
- 5- Metoprolol

Answer & Comments

Answer: 4- Lithium

This lady has eunatraemia, hypertonicity (high serum osmolality) and inappropriately dilute urine) which is consistent with Diabetes insipidus. Of the drugs listed Lithium would be the most likely to cause a nephrogenic DI.

[Q: 682] OnExamination - Endocrinology

A 32-year-old woman with known hypothyroidism is admitted to hospital. Her Blood pressure is 86/53 mmHg and her pulse 100 bpm. Investigations reveal:

Serum sodium 126 mmol/l (133-145)

Serum potassium 5.8 mmol/l (3.5-5.0)

Serum glucose 3.0 mmol/l (3.5-6.0)

What is the most appropriate investigation?

- 1- Anti-thyroglobulin antibody

- 2- Plasma insulin concentration
- 3- Random serum cortisol concentration
- 4- Short synacthen test
- 5- Urine and plasma osmolality

Answer & Comments

Answer: 4- Short synacthen test

This young woman probably has an autoimmune hypothyroidism and now presents with features typical of acute hypoadrenalism. The biochemistry is also supportive with low sodium, low glucose and elevated potassium. The diagnosis may be confirmed with inadequate cortisol response in the short synacthen test. A random cortisol concentration is not adequate to diagnose hypoadrenalism.

[Q: 683] OnExamination - Endocrinology

An 18-year-old male presented with delayed pubertal development. He had always noted an impaired sense of smell. Examination revealed that his height was on 90th centile and his weight on the 90th centile. His external genitalia showed a small penis with testicular volumes of 3 mL bilaterally and no pubic hair. Investigations revealed: LH concentration 1.0 U/L (1-10), FSH concentration 1.0 U/L (1-7), Serum testosterone 3.0 pmol/L (9-35), Free T₄ 19 pmol/L (10-22), TSH 3.0 mU/L (0.4-5), CT scan reported as normal.

What is the most likely diagnosis?

- 1- Constitutional delay of puberty
- 2- Kallmann's syndrome.
- 3- Klinefelter's syndrome.
- 4- Noonan's syndrome.
- 5- Prader-Willi syndrome.

Answer & Comments

Answer: 2- Kallmann's syndrome.

The combination of hypogonadotrophic hypogonadism and anosmia would suggest a diagnosis of Kallmann's syndrome. This is one of the commonest causes of isolated hypogonadotrophic hypogonadism and is due to a failure of migration of the olfactory neurones and GnRh neurones during development.

[Q: 684] OnExamination - Endocrinology

Which of the following statements is true of Type 2 Diabetes Mellitus?

- 1- 20% of patients develop macrovascular complications within 10 years of diagnosis
- 2- Drug treatment is associated with a 25% reduction in microvascular complications compared with diet alone.
- 3- A single fasting plasma glucose above 8 mmol/L is diagnostic of diabetes.
- 4- Type 2 diabetes is associated with being underweight
- 5- Metformin is the preferable treatment in the obese patient with type 2 diabetes

Answer & Comments

Answer: 5- Metformin is the preferable treatment in the obese patient with type 2 diabetes

[Q: 685] OnExamination - Endocrinology

Which of the following doses of prednisolone is equivalent in its glucocorticoid potency to 20mg of hydrocortisone.

- 1- 2 mg
- 2- 5 mg
- 3- 10 mg
- 4- 15 mg

5- 20 mg

Answer & Comments

Answer: 2- 5 mg

It is important to know the relative potencies of the glucocorticoids. Dexamethasone for instance is roughly 30 times more potent than hydrocortisone.

[Q: 686] OnExamination - Endocrinology

An elderly asthmatic lady on treatment with high dose prednisolone, complains of a 4 week history of right hip pain. She comments that recently she seems to be developing more facial hair and adds that she has also been diagnosed with high blood pressure and diabetes. On examination she is noted to be unable to weight bear on the right side.

What is the most likely cause of her hip pain?

- 1- Avascular necrosis of femoral head
- 2- Dislocation of the hip joint
- 3- Fracture neck of femur
- 4- Gout
- 5- Osteoarthritis of the hip joint

Answer & Comments

Answer: 1- Avascular necrosis of femoral head

This question simply tests the knowledge of side-effects of corticosteroids (a favourite theme in MRCP 1). The patient has features of hypercortisolism. Obviously, avascular necrosis of femoral head is the cause of her right hip pain.

[Q: 687] OnExamination - Endocrinology

A 35-year-old male presents with weakness and tiredness. He is noted to be hypertensive. Electrolytes show a hypokalaemia and a hypomagnesaemia.

What investigation would you select for this patient?

- 1- Colonoscopy
- 2- Plasma renin toaldosterone ratio
- 3- Serum amylase
- 4- Serum calcium
- 5- Oral glucose tolerance test

Answer & Comments

Answer: 2- Plasma renin toaldosterone ratio

The hypokalaemic hypertension with hypomagnesaemia suggests primary hyperaldosteronism. The most reliable assessment for this would be renin to aldosterone ratio.

[Q: 688] OnExamination - Endocrinology

Testosterone

- 1- Is a steroid hormone
- 2- Acts via cell surface receptors
- 3- Acts via g-protein second messengers
- 4- Is manufactured through the breakdown of oestradiol
- 5- In the circulation is mostly bound to albumin

Answer & Comments

Answer: 1- Is a steroid hormone

Testosterone is a steroid hormone receptor and can be converted to oestradiol. It binds to intra-cellular receptors and is mostly bound to sex-hormone binding globulin.

[Q: 689] OnExamination - Endocrinology

A 42-year-old man being investigated for diabetes and impotence is noted to have the following results:

Alanine aminotransferase 30 U/L (5-35)
 Aspartate aminotransferase 22 U/L (1-31)
 Fasting plasma glucose 7.4 mmol/L (3.0-6.0)
 Ferritin 500 ug/L (15-300)

Which one of the following would be the next most appropriate investigation?

- 1- bone marrow smear and iron stain
- 2- liver biopsy
- 3- Red cell protoporphyrins
- 4- serum transferrin receptors
- 5- transferrin saturation

Answer & Comments

Answer: 5- transferrin saturation

This patient has a suspected diagnosis of haemochromatosis as suggested by the presentation and laboratory investigations including elevated ferritin. The next investigation would be measurement of transferrin saturation and then if elevated (above 45%) genotyping (Homozygosity for C282Y mutations) would next be considered and would be expected to clinch the diagnosis. In the event of rarer mutations confirmation with liver biopsy may be required.

[Q: 690] OnExamination - Endocrinology

A diagnosis of diabetes mellitus is being considered in 32-year-old woman who is 16 weeks pregnant. Her body mass index (BMI) was 22 kg/m² (18 - 25). A 75g oral glucose tolerance test revealed:

Time	Plasma glucose concentration
0 hr	6.0 mmol/l (3.0-6.0)
2hr	12.5 mmol/l (<11.1)

Which of the following is the most appropriate step in the management of this patient?

- 1- Low calorie diet
- 2- Glipizide therapy

3- Metformin therapy

4- Repeat her oral glucose tolerance test in four weeks

5- Insulin therapy

Answer & Comments

Answer: 5- Insulin therapy

The result confirms a diagnosis of gestational diabetes mellitus with the 2hr OGTT result above 11.1 mmol/l. To minimise the fetal consequences of GDM (macrosomia, fetal malformations, still birth, IUGR etc), the patient's glycaemia should be strictly controlled with insulin. A low calorie diet is inappropriate and neither metformin nor glipizide are licenced for use in pregnancy. There is no point in repeating the OGTT in 4 weeks as control is required NOW.

[Q: 691] OnExamination - Endocrinology

A 64-year-old female is diagnosed with osteoporosis and is receiving treatment with Raloxifene.

What is raloxifene?

- 1- A synthetic oestrogen
- 2- A bisphosphonate
- 3- An androgenic steroid
- 4- A selective androgen receptor modulator (SARM)
- 5- A selective oestrogen receptor modulator (SERM)

Answer & Comments

Answer: 5- A selective oestrogen receptor modulator (SERM)

Raloxifene, like tamoxifen is a SERM, with oestrogen like activity at sites like bone but anti-oestrogen like effects on breast/endometrium.

[Q: 692] OnExamination -
Endocrinology

Side effects of recombinant human growth hormone therapy include:

- 1- Proliferative retinopathy
- 2- Aplastic anaemia
- 3- Leukaemia
- 4- Creutzfeldt-Jacob disease
- 5- Benign Intracranial hypertension

Answer & Comments

Answer: 5- Benign Intracranial hypertension

Unlike the old pituitary derived GH, rhGH is not associated with CJD as it is manufactured by recombinant techniques. rhGH therapy has been associated with BIH probably due to the fluid retention associated with GH therapy.

[Q: 693] OnExamination -
Endocrinology

Non-alcoholic steatohepatitis is associated with which of the following?

- 1- A benign course in all cases
- 2- Alcohol abuse
- 3- Insulin resistance
- 4- Normal level of liver enzymes
- 5- Viral hepatitis

Answer & Comments

Answer: 3- Insulin resistance

Non-alcoholic steatohepatitis (NASH) is associated with insulin resistance, hyperlipidaemia and chronic moderately elevated liver enzymes. The diagnosis is made only by histology of liver biopsy which shows lesions suggestive of ethanol intake in a patient known to consume less than 40g of alcohol per week. It is not necessarily benign: cryptogenic cirrhosis in patients is a

substantial number of probably end-stage NASH.

[Q: 694] OnExamination -
Endocrinology

A 70-year-old female who is receiving amiodarone for paroxysmal atrial fibrillation presents with tiredness and weight loss.

Investigations reveal:

C-reactive protein 6 mg/L (<10)

free Thyroxine 38 pmol/L (10-22)

TSH <0.05 mU/L (0.5-4.5)

Which is the most appropriate treatment for this patient?

- 1- Carbimazole
- 2- Lithium therapy
- 3- Prednisolone
- 4- Radioiodine therapy
- 5- thyroidectomy

Answer & Comments

Answer: 1- Carbimazole

The most appropriate initial treatment of this amiodarone induced hyperthyroidism would be carbimazole. Despite stopping the amiodarone thyrotoxicosis may persist for many months and so additional treatment is often required. Two types of amiodarone induced hyperthyroidism are recognised. The first being a consequence of iodine overload contained within the amiodarone of which the above is a typical example and the second type is due to an acute thyroiditis with thyroid cell destruction and increased parameters of inflammation. The former is best treated with carbimazole, the latter with prednisolone.

[Q: 695] OnExamination -
Endocrinology

Which of the following best describes the mode of action of alendronate?

- 1- inhibits osteoclast activity
- 2- promotes bone matrix calcification
- 3- promotes collagen synthesis
- 4- promotes renal absorption of calcium
- 5- stimulates osteoblast activity

Answer & Comments

Answer: 1- inhibits osteoclast activity

Simple bisphosphonates such as clodronate and etidronate inhibit bone resorption through induction of osteoclast apoptosis. Clodronate, and perhaps etidronate, triggers apoptosis by generating a toxic analog of adenosine triphosphate, which then targets the mitochondria. For nitrogen-containing bisphosphonates, the direct intracellular target is the enzyme farnesyl diphosphate synthase in the cholesterol biosynthetic pathway. Its inhibition suppresses a process called protein geranylgeranylation, which is essential for the basic cellular processes required for osteoclastic bone resorption. Although nitrogen-containing bisphosphonates can induce osteoclast apoptosis, this is not necessary for their inhibition of bone resorption.

[Q: 696] OnExamination - Endocrinology

A 32 year-old woman presents with a one year history of secondary amenorrhoea. She had been prescribed temazepam and dihydrocodeine. On examination she had galactorrhoea. Her serum prolactin was noted to be 6000 mU/l (<450 mU/l).

What is the most likely diagnosis?

- 1- Drug-induced hyperprolactinaemia
- 2- Hypothyroidism
- 3- Pituitary dependent Cushing's disease
- 4- Pituitary microadenoma
- 5- Stress

Answer & Comments

Answer: 4- Pituitary microadenoma

The patient has amenorrhoea, galactorrhoea and a grossly elevated prolactin concentration of 6000. The diagnosis is likely to be a prolactinoma most likely due to a pituitary microadenoma (microprolactinoma). These drugs would not cause hyperprolactinaemia ?drugs that are responsible include dopamine antagonists ?Antipsychotics (Haloperidol, Sulpiride), metoclopramide, Domperidone and SSRIs to a lesser extent. There is nothing in this patients history to suggest either hypothyroidism or Cushing's.

Hypothyroidism may cause hyperprolactinaemia but is usually mild. Stress would not produce such a picture.

[Q: 697] OnExamination - Endocrinology

A 62-year-old woman presents with stridor associated with a retro-sternal goitre.

What is the most appropriate investigation of her airways obstruction?

- 1- FEV₁/FVC ratio
- 2- Flow-volume loop
- 3- Peak Expiratory Flow Rate
- 4- Spirometry
- 5- Transfer factor

Answer & Comments

Answer: 2- Flow-volume loop

The flow volume loop is the best method of for detecting an obstruction associated with a retrosternal mass.

[Q: 698] OnExamination - Endocrinology

A 44-year-old man presents with new onset bilateral gynaecomastia. He has been diagnosed with Zollinger-Ellison syndrome in

the last year. He underwent normal puberty at age 14.

Which of the following is the most likely cause of this mans gynaecomastia?

- 1- Cimetidine
- 2- Famotidine
- 3- Lanzoprazole
- 4- Rabeprazole sodium
- 5- Ranitidine

Answer & Comments

Answer: 1- Cimetidine

The answer to this question is cimetidine which is an H2 receptor antagonist. Blockade of androgen-responsive receptors in the target organ appears to be the most likely mechanism involved. Research has shown that the other drugs listed above which may also be used as part of the treatment of Zollinger-Ellison syndrome have a much lower almost insignificant risk in the development of gynaecomastia.

Other drugs that can cause gynaecomastia include - spironolactone, digoxin, methyl dopa, gonadotrophins and cyproterone acetate.

Zollinger-Ellison syndrome

The association of peptic ulcer with a gastrin-secreting pancreatic adenoma - 50-60% are malignant. It occurs in approx 0.1% of patients with duodenal ulcer disease and is to be suspected in those with multiple peptic ulcers that are resistant to drugs.

[Q: 699] OnExamination - Endocrinology

A 26-year-old female presents with a six weeks history of galactorrhoea. She has no other symptoms but takes medication for contraception, dyspepsia and migraine. Examination reveals slight galactorrhoea with

expression from both breasts but is otherwise normal.

Investigations show:

" Prolactin 915 mU/L (< 450)

Which one of the following drugs may be responsible?

- 1- Codeine phosphate
- 2- Metoclopramide
- 3- Omeprazole
- 4- Oral contraceptive pill
- 5- Sumatriptan

Answer & Comments

Answer: 2- Metoclopramide

Metoclopramide acts as a dopamine antagonist. Dopamine inhibits the release of Prolactin from the anterior Pituitary gland. Therefore, metoclopramide can predispose to hyperprolactinaemia and consequent galactorrhoea.

[Q: 700] OnExamination - Endocrinology

A 36-year-old man attends clinic with his wife after failing to conceive after 10 years of marriage. Examination reveals that he is tall, thin and has bilateral gynaecomastia. Investigations show high levels of urinary gonadotrophins.

What is the most likely diagnosis?

- 1- Andropause
- 2- Gaucher's disease
- 3- Klinefelter's syndrome
- 4- Marfan syndrome
- 5- Noonan's syndrome

Answer & Comments

Answer: 3- Klinefelter's syndrome

Gaucher's and Marfan syndrome do not present with infertility. Noonan's is associated with short stature. Klinefelter's is a sex chromosome disorder affecting 1:400 - 1:600 male births typically with 47 XXY, XXXYY or XXYY. Andropause is the term for the gradual decrease in serum testosterone concentration with age, but does not occur, usually, until after the age of 50.

[Q: 701] OnExamination - Endocrinology

A 17-year-old female is referred with a six month history of amenorrhoea and weight loss, for which no organic cause can be found.

Which of the following features would support a diagnosis of anorexia nervosa?

- 1- Delusions of poisoning
- 2- Hypotrichosis
- 3- Hypergonadotrophic hypogonadism
- 4- Delusion of being overweight
- 5- Watery diarrhoea

Answer & Comments

Answer: 4- Delusion of being overweight

Features of AN include a phobic avoidance of normal weight, relentless dieting, self-induced vomiting, laxative use, excessive exercise, amenorrhoea, lanugo hair, hypotension, denial, concealment, overperception of body image, enmeshed families.

[Q: 702] OnExamination - Endocrinology

A 55-year-old obese man with Type 2 DM is uncontrolled on diet alone.

Which of the following oral hypoglycaemic therapies functions through improving insulin sensitivity

- 1- acarbose
- 2- glimepiride

- 3- glipizide
- 4- repaglinide
- 5- rosiglitazone

Answer & Comments

Answer: 5- rosiglitazone

Rosiglitazone, a PPAR gamma agonist is an insulin sensitiser. Its exact mechanism of action is not fully appreciated but it improves muscle glucose utilisation and also hepatic glucose uptake.

[Q: 703] OnExamination - Endocrinology

Which of the findings listed below is true of Acromegaly?

- 1- A random growth hormone concentration may be diagnostically useful.
- 2- It is unusual for the pituitary fossa to be enlarged.
- 3- Pituitary hormones other than growth hormone are rarely affected.
- 4- The majority of patients demonstrate an abnormal glucose tolerance test.
- 5- Growth hormone concentrations are suppressed to normal by bromocriptine therapy.

Answer & Comments

Answer: 4- The majority of patients demonstrate an abnormal glucose tolerance test.

Random GH concentrations are pretty useless in the diagnosis of acromegaly which depends upon non-suppression of GH in the Oral Glucose tolerance test in which approx 50% have either impaired GTT or diabetes. GH concentrations seldom suppress to normal with bromocriptine but often respond far better with Octreotide. C is awkward but prolactin is often elevated (30%) although

hypopituitarism would be unusual unless the tumour is particularly large. Usually at presentation the fossa is enlarged (about 80%).

[Q: 704] OnExamination - Endocrinology

An 18 year-old girl receives radioactive iodine as treatment of thyrotoxicosis.

Which of the following is the most likely long-term complication of this treatment?

- 1- hypoparathyroidism
- 2- hypothyroidism
- 3- increased risk of developing cancer
- 4- recurrent laryngeal nerve damage
- 5- osteoporosis

Answer & Comments

Answer: 2- hypothyroidism

RAI is safe and that is why it is given across all ages as a definitive treatment of thyrotoxicosis. The most likely side effect of radioactive iodine is hypothyroidism with approx 80% developing hypothyroidism after therapy. There is no evidence to suggest that RAI is associated with any cancers. However, RAI must not be given to pregnant females particularly after the 12th gestational week as it would be taken up by the developing foetal thyroid causing fetal hypothyroidism and is also considered to be teratogenic. Recurrent laryngeal nerve damage is a potential risk of thyroid surgery, not RAI.

[Q: 705] OnExamination - Endocrinology

In the treatment of osteoporosis, which of the following best describe the drug Raloxifene?

- 1- A Bisphosphonate
- 2- A Calcium Receptor Modulator
- 3- An Estrogen

4- A PTH receptor agonist

5- A Selective Estrogen Receptor Modulator

Answer & Comments

Answer: 5- A Selective Estrogen Receptor Modulator

Raloxifene is the first of the so-called Selective Estrogen Receptor Modulators. There are fundamentally two types of estrogen receptor, alpha and beta, distributed at locations such as breast, uterus, bone and in the vasculature. Raloxifene acts as an estrogen agonist at some sites eg Bone to increase mineralisation but acts as an antagonist at other sites eg uterus/breast (preventing endometrial/breast hyperplasia).

[Q: 706] OnExamination - Endocrinology

A 21-year-old male is referred to the endocrine clinic with poorly developed secondary sexual characteristics. The only relevant finding on history is that he has a very poor sense of smell. On examination he has no axillary or pubertal hair, a 3cm penis and testicular volumes of approximately 5mls bilaterally. Smell test reveals that he is unable to distinguish acetone and coffee.

Investigations reveal:

Testosterone 4 nmol/L (10-30)

Prolactin 380 mU/L (< 450)

FSH 2.1 iu/L (1-7)

LH 1.5 iu/L (1-10)

What is the most likely diagnosis?

- 1- 5-alpha reductase deficiency
- 2- Craniopharyngioma
- 3- Kallman's syndrome
- 4- Klinefelter's syndrome
- 5- Microdeletion of the Y chromosome

Answer & Comments

Answer: 3- Kallman's syndrome

This patient has evidence of hypogonadotrophic, hypogonadism with a low testosterone and a low FSH and LH. In this case, there is isolated gonadotrophic deficiency as evidence by a normal prolactin, this is seen in Kallman's syndrome, which is often associated with anosmia.

In Klinefelter's syndrome an elevated LH/FSH would be expected as this is due to testicular failure, as would be the case in 5-alpha reductase deficiency. Craniopharyngioma is a possibility as it does cause hypogonadotrophic hypogonadism but abnormalities in sense of smell would not be expected.

[Q: 707] OnExamination - Endocrinology

A 60-year-old man presents with inspiratory stridor with a Chest X-ray revealing compression of the trachea by a retrosternal goitre.

Which of the following investigations is the most useful to assess the severity of his airways obstruction?

- 1- flow/volume loop
- 2- forced expiratory volume
- 3- forced vital capacity
- 4- peak expiratory flow rate
- 5- residual volume

Answer & Comments

Answer: 1- flow/volume loop

A flow volume loop is the most appropriate investigation to assess severity of the obstruction.

[Q: 708] OnExamination - Endocrinology

In a study, healthy volunteers are given 50 mls

of 50% dextrose solution by one of two routes. Route A is intravenous and Route B is via a nasogastric tube. Every 15 minutes the plasma insulin level and glucose is measured and plotted on a graph.

Which of the following statements would best describe the likely results comparing Route A to Route B in this experiment?

- 1- insulin higher, glucose higher in Route A
- 2- insulin higher, glucose higher in Route B
- 3- insulin higher, glucose lower in Route A
- 4- insulin higher, glucose lower in Route B
- 5- insulin and glucose the same in Route A and Route B

Answer & Comments

Answer: 4- insulin higher, glucose lower in Route B

Glucose given via the gut elicits a greater insulin response as compared to the same quantity given intravenously even though the plasma glucose peak is higher when it is given IV. This phenomenon is called the 'incretin effect'.

The incretin effect denominates the phenomenon that oral glucose elicits a higher insulin response than does intravenous glucose. The two hormones responsible for the incretin effect, glucose-dependent insulinotropic hormone (GIP) and glucagon-like peptide-1 (GLP-1), are secreted after oral glucose loads and augment insulin secretion in response to hyperglycemia. Gastric Inhibitory Polypeptide and Glucagon-Like Peptide-1 in the Pathogenesis of Type 2 Diabetes. Diabetes 53:S190-S196, 2004

The investigation of the incretin effect is not usually performed using the same quantity of glucose as in this question. An 'isoglycaemic study' is often used where an infusion of glucose is designed to copy exactly the blood glucose profile generated in an individual or animal by a certain enteral glucose load.

Exenatide (synthetic exendin-4) is a new agent for the treatment of Type 2 Diabetes. Exendin-4 occurs naturally in the saliva venom of the North American lizard called the Gila Monster. It mimics the action of the gut hormone GLP-1 (Glucagon-like peptide 1).

[Q: 709] OnExamination - Endocrinology

A 62-year-old female with a six year history of type 2 diabetes attends for annual review. Her HbA1c is 10%.

Into what average plasma glucose concentration does her HbA1c translate?

- 1- 7.5 mmol/l
- 2- 10 mmol/l
- 3- 12.5 mmol/l
- 4- 15.5 mmol/l
- 5- 19 mmol/l

Answer & Comments

Answer: 4- 15.5 mmol/l

The HbA1c is an important reflection of control over a 3 month period (life expectancy of the erythrocyte). There is a good relationship between the rise in glucose and its ability to glycosylate the Hb molecule (there's a difference between average plasma glucose and blood glucose, if you are looking at the link provided it should be obvious). Thus a HbA1c of 7% would translate into an average PLASMA (higher than value of BLOOD glucose) glucose of 9.5 mmol/l and a HbA1c of 10% into 15.5 mmol/l. This is the reason why so much emphasis is placed on controlling HbA1c rather than the specific glucose measurements as these vary so much throughout the day.

[Q: 710] OnExamination - Endocrinology

A type 1 diabetic displays typical symptoms of

hypoglycaemic unawareness.

Which of the following statements regarding hypoglycaemic unawareness is correct?

- 1- Glucose sensing occurs in the locus caeruleus
- 2- Recurrent hypoglycaemia is most commonly associated with poor diabetic control
- 3- Recurrent hypoglycaemia has no long term consequences on higher cerebral function
- 4- D Selective beta-blockers are an important cause of hypoglycaemia unawareness
- 5- Alcohol inhibits gluconeogenesis in patients with hypoglycaemia unawareness

Answer & Comments

Answer: 5- Alcohol inhibits gluconeogenesis in patients with hypoglycaemia unawareness

Alcohol inhibits gluconeogenesis, decreases peripheral hypoglycaemic responses and impairs perception of symptoms of hypoglycaemia. There is no evidence to suggest that beta-blockers cause hypoglycaemia unawareness. Glucose sensing occurs in the hypothalamus, and there is evidence to suggest that chronic, and recurrent hypoglycaemia may have deleterious effects on higher cerebral function.

[Q: 711] OnExamination - Endocrinology

A 26-year-old female with no previous history of diabetes presents with a first episode of diabetic ketoacidosis. There is no evidence of infection but she has recently commenced a new medication.

Which of the following drugs is implicated in precipitating diabetic ketoacidosis?

- 1- Olanzapine
- 2- Omeprazole
- 3- Progestogen only contraceptive pill

4- Sodium valproate

5- Venlafaxine

Answer & CommentsAnswer: 1- Olanzapine

The atypical antipsychotics such as Olanzapine have been implicated in precipitating diabetes as well as diabetic ketoacidosis. Other drugs implicated include thiazide diuretics, beta sympathomimetics and steroids.

[Q: 712] OnExamination -
Endocrinology

A 22-year-old female student presents acutely unwell with vomiting and dehydration. She has a two month history of weight loss and thirst. Investigations confirm a diagnosis of diabetic ketoacidosis with a glucose of 29.3 mmol/l (3.5-5.5), a pH of 7.12 (7.35-7.45) on blood gas analysis and urinalysis reveals +++ ketones.

What percentage of Type 1 diabetics are initially diagnosed following presentation with diabetic ketoacidosis?

- 1- 5%
- 2- 10%
- 3- 15%
- 4- 25%
- 5- 40%

Answer & CommentsAnswer: 4- 25%

Approximately 25% of Type 1 diabetics will first present in diabetic ketoacidosis although often there are symptoms such as thirst, polyuria and weight loss which have been ignored.

[Q: 713] OnExamination -
Endocrinology

A 70-year old type 2 diabetic for 20 years is

referred to the clinic because of poor glycaemic control despite recent dietetic input. He has a history of previous 2 myocardial infarctions, and gets exertional angina at 50 yards. He has previously had angioplasty to both his lower limbs and despite this has a claudication distance of 40 yards. He is in New York heart failure class 2-3. Additionally he has diabetic maculopathy, and distal sensory neuropathy. His home blood monitoring readings are 10-15 before breakfast. His current treatment includes Metformin 500mg tds, Glimepiride 4mg daily, Insulin glargine 20units at night. Perindopril 8mg od, Furosemide 80mg daily, Aspirin 75mg daily, Atorvastatin 20mg daily. On examination his BMI is 30, with a BP of 140/70mmHg.

HbA1c 9.2%

fasting glucose 13.4 mmol/l (3.5-6)

Creatinine 130 μ mol/l (50-100)

Liver function Normal.

What is the most appropriate strategy to improve his glycaemic control?

- 1- Add prandial insulin (eg Novorapid) tds
- 2- Add premixed insulin (eg humalog 25) bd and stop Lantus
- 3- Add Rosiglitazone 4mg daily
- 4- Substitute metformin with Avandamet 4/500mg bd
- 5- Up titrate the dose of Insulin glargine

Answer & CommentsAnswer: 5- Up titrate the dose of Insulin glargine

This patient has uncontrolled glycaemia despite maximal oral therapy and dietary intervention. Rosiglitazone is already contraindicated because of the history of heart failure and the use of insulin. The current basal insulin regime of Glargine is failing to control his glycaemia, however the

current dose is inadequate. Current practice would favour increasing the dose of lantus aiming for a fasting (pre breakfast) BM of <7.0. Only once fasting readings of this level are achieved with a sub optimal HbA1c would one think of adding a prandial insulin. The caveat would be nocturnal hypoglycaemia however this was not mentioned in the vignette.

[Q: 714] OnExamination -
Endocrinology

A 62-year-old type 2 diabetic for 10 years attends for his annual review. His home blood glucose levels are 7-10 pre breakfast, he remains overweight despite following his diet and being regularly active, unfortunately he still smokes 10 cigarettes a day. His medication includes Metformin 850mg tds, Gliclazide 160mg bd, Simvastatin 40mg od, Aspirin 75mg od, Ramipril 10mg od. On examination his blood pressure is 145/85mmHg with a BMI of 31.2, he has background diabetic retinopathy, with a distal sensory neuropathy. His pre clinic biochemistry is as follows.

HbA1c 8.5% (<6%)

Fasting glucose 10.5mmol/l (3.5-6)

Serum creatinine 190 µmol/l (50-100)

eGFR 40ml/min/1.73m₂

Total Cholesterol 5.5 mmol/l (<5.5)

LDL cholesterol 3.2 mmol/l (<4)

HDL cholesterol 0.95 mmol/l (1-2)

Urine albumin creatinine ratio 10mg/mmol

What is the appropriate intervention?

- 1- Add insulin glargine to current treatment
- 2- Add Novorapid tds and insulin glargine
- 3- Add Rosiglitazone 4mg/day
- 4- Stop Gliclazide and Metformin and use insulin glargine.
- 5- Stop Metformin and commence insulin glargine

Answer & Comments

Answer: 5- Stop Metformin and commence insulin glargine

This patient has diabetic nephropathy as evidence by proteinuria, hypertension and eGFR consistent with stage 3 chronic kidney disease. Current practice recommends the discontinuation of metformin if there is evidence of a reduced glomerular filtration rate evidence by a creatinine of >130µmol/l or eGFR <60ml/min/1.73m². Therefore Metformin should be stopped; this will lead to inevitable decline in overall diabetic control, which will need insulin therapy, which can be used alongside the sulphonylurea gliclazide. The use of rosiglitazone is relatively contraindicated given the renal impairment.

[Q: 715] OnExamination -
Endocrinology

A 52-year-old male with a history of dyslipidaemia and hypertension attends the surgery for a 75g oral glucose tolerance test (OGTT) as part of his cardiovascular risk assessment and screening for type 2 diabetes. He is overweight with a BMI of 29 kg/m², his blood pressure is 135/85 mmHg on a combination of Amlodipine and Perindopril.

His venous plasma OGTT result is as follows.

0 minutes 6.3

120 minutes 10.4

Which of the following do these results suggest?

- 1- Impaired fasting glucose (IFG)
- 2- Impaired fasting glucose and impaired glucose tolerance
- 3- Impaired glucose tolerance (IGT)
- 4- Normal glucose tolerance.
- 5- Type 2 diabetes

Answer & Comments

Answer: 2- Impaired fasting glucose and impaired glucose tolerance

The WHO recommend the use of the OGTT for the diagnosis of type 2 diabetes as it incorporates the fasting and 2 hour post glucose load which can identify different sub groups of diabetic patients and different categories of individuals at risk of type 2 diabetes.

The diagnostic criteria are:

Venous plasma glucose Fasting (mmol/l)

2 hour post glucose (mmol/l)

Diabetic > 7.0 > 11.1

IGT <7.0 7.8-11.0

IFG 6.1-6.9 <7.8

In the absence of marked hyperglycaemia and symptoms such as weight loss, polyuria or polydipsia these results should be confirmed by a repeat test on another day.

[Q: 716] OnExamination - Endocrinology

When considering diabetic retinopathy which of the following statements is most accurate:

- 1- Microaneurysms represent sacular dilatation of retinal arterioles
- 2- Hard exudates represent calcium deposits in the retina
- 3- Cotton wool spots represent infarcts of the nerve fibre layer of the retina
- 4- Haemorrhages close to the fovea are not potentially sight threatening
- 5- Laser photocoagulation is applied directly to new vessels to destroy them

Answer & Comments

Answer: 3- Cotton wool spots represent infarcts of the nerve fibre layer of the retina

MAAs are capillary aneurysms. HEs are collections of exudated lipid and protein. C is correct, multiple CWS are a pre-proliferative sign. Haemorrhages (or HEs) close to the fovea represent a risk of macular oedema and are therefore sight threatening. Laser destroys ischaemic but viable retina to reduce the secretion of angiogenic growth factors and allow new vessel regression, it is not applied directly to new vessels as this would cause bleeding.

[Q: 717] OnExamination - Endocrinology

A 32-year-old male physical education teacher has a 3 year history of type 1 diabetes. At the last annual review, his HbA1c was 6.8% but he complains of hypoglycaemic events particularly during exercise. He has been commenced on the insulin analogue - Lispro insulin.

Compared with conventional short-acting insulins what is the advantage of insulin analogue therapy?

- 1- Significant improvement in HbA1c
- 2- Reduces post-prandial glucose concentrations
- 3- Reduces the incidence of long-term diabetic complications
- 4- Reduces the incidence of hypoglycaemic events
- 5- Longer duration of action

Answer & Comments

Answer: 2- Reduces post-prandial glucose concentrations

The short acting Insulin analogue, Lispro has a rapid onset of action and a shorter duration of action than conventional short acting soluble insulins. Consequently studies reveal reduced post-prandial glucose concentrations versus soluble insulin and potentially a reduced

incidence of hypoglycaemia although the evidence for this is lacking.

[Q: 718] OnExamination - Endocrinology

A 50-year-old man with a history of Diabetes Mellitus and hypertension attends an ophthalmic clinic for regular assessment. On fundoscopy he is diagnosed to have preproliferative diabetic retinopathy.

Which of the following is characteristic of preproliferative diabetic retinopathy?

- 1- New vessels at the disc
- 2- Microaneurysms
- 3- Hard Exudates
- 4- Venous Beading
- 5- Macular Odema

Answer & Comments

Answer: 4- Venous Beading

2,3 and 5 suggest background diabetic retinopathy. Venous beading, loops and soft exudates (cotton wool spots) are characteristic of preproliferative diabetic retinopathy. New vessels suggest proliferative retinopathy.

[Q: 719] OnExamination - Endocrinology

A 43-year-old male is diagnosed with diabetic nephropathy. If this patient had type 1 diabetes his chances of progressing to End Stage Renal Disease (ESRD) would be approximately 50%.

What percentage of type II diabetics with diabetic nephropathy would be expected to progress to ESRD?

- 1- 15%
- 2- 30%
- 3- 45%
- 4- 50%

5- 55%

Answer & Comments

Answer: 1- 15%

Although the incidence of diabetic nephropathy is less in type 2 diabetics as approximately 90-95% of all diabetics are type IIs, the majority of patients with diabetic nephropathy are type II diabetics. There are a number of stages in the development of nephropathy with glomerular hyperfiltration being an early feature. Nephropathy itself is signaled by the excretion of trace amounts of protein in the urine ?microalbuminuria. The progression of the disease may be attenuated by stringent blood pressure control (with an ACEi) and strict glycaemic control.

[Q: 720] OnExamination - Endocrinology

A 72-year-old male presents with a 2 month history of weight loss and weakness. Examination reveals a BMI of 24.5 kg/m² and a blood pressure of 146/90 mmHg. Examination of the lower limbs reveals a bilateral weakness of knee extension. He is unable to rise from the squatting position. There is absence of the knee reflex but the ankle reflexes are preserved and both plantars are flexor. There are no abnormalities on sensory examination.

Which of the following tests may be diagnostic?

- 1- Vitamin B₁₂ concentration
- 2- Thyroid function test
- 3- Oral glucose tolerance test
- 4- Urine free cortisol concentration
- 5- Vitamin D concentration

Answer & Comments

Answer: 3- Oral glucose tolerance test

This patient presents with weight loss, and reduced quadriceps strength, bilaterally with

absent knee reflexes. This is a typical presentation of diabetic amyotrophy. Osteomalacia, hyperthyroidism and Cushing's would be unlikely as the proximal myopathy involves quadriceps and hamstrings and knee reflexes would be preserved. Subacute combined degeneration of the cord does not present with such features.

[Q: 721] OnExamination - Endocrinology

A 64-year-old retired Caucasian solicitor attends the surgery. He is overweight and takes little exercise. He has been treated for hypertension for 5 years and is controlled on 5mg of Ramipril. He also takes 20mg of Simvastatin for hypercholesterolaemia. A 75g oral glucose tolerance test was recently performed and gave a result consistent with impaired glucose tolerance (IGT) with a 2 hour plasma glucose concentration of 9.3mmol/l. The patient is keen to know what would be his risk of developing type 2 diabetes.

What do you tell him?

- 1- 6% over 6 years
- 2- 10% over 6 years
- 3- 33% over 6 years
- 4- 60% over 6 years
- 5- 100% over 6 years

Answer & Comments

Answer: 3- 33% over 6 years

Individuals with IGT are at significant risk of progression to type 2 diabetes. A number of studies have looked at the absolute risk of progression from IGT to type 2 diabetes. The large and widely quoted Hoorn study which looked at 1342 Caucasian non-diabetic subjects found that 33.8% progressed to type 2 diabetes over 6 years follow up. This increased to 64.5% if individuals had both IGT and IFG. A similar rate of progression for individuals with IGT was Vaccaro who studied

a Caucasian group in Italy. Intensive lifestyle changes involving diet changes, regular exercise and weight loss have been shown to reduce the rate of progression to type 2 diabetes.

[Q: 722] OnExamination - Endocrinology

A 45-year-old man with Type 2 Diabetes is being treated with Exenatide.

Which of the following would be a recognised adverse effect of his treatment?

- 1- Hyperglycaemia
- 2- Hypertension
- 3- Peripheral oedema
- 4- Renal impairment
- 5- Weight loss

Answer & Comments

Answer: 5- Weight loss

Exenatide (synthetic exendin-4) is a new agent for the treatment of Type 2 Diabetes. Exendin-4 occurs naturally in the saliva venom of the North American lizard called the Gila Monster. It mimics the action of the gut hormone GLP-1 (Glucagon-like peptide 1). It causes hypoglycaemia (which is its therapeutic effect) especially when used in combination with oral antidiabetic drugs, weight loss, nausea and other gastrointestinal side effects.

[Q: 723] OnExamination - Endocrinology

A 32-year-old male with type 1 diabetes undergoes a 24 hour urine collection.

Which of the following urine albumin concentrations signify microalbuminuria?

- 1- 10 mg/day
- 2- 50 mg/day
- 3- 500 mg/day
- 4- 1g/day

5- 3.5 g/day

Answer & CommentsAnswer: 2- 50 mg/day

Microalbuminuria is defined as a urine albumin excretion of between 20-200 micrograms/min urine or between 30-300 mg/day. A concentration above 300 mg/day signifies albuminuria and a concentration above 3.5g/day signifies overt proteinuria. Microalbuminuria is not just an indicator of early renal involvement but it also identifies increased cardiovascular risk with an approximate two fold cardiovascular risk above the already increased risk in the diabetic population. A useful surrogate of the total albumin excretion is the albumin:creatinine ratio. The urinary albumin:creatinine ratio is measured using the first morning urine sample where practicable. Microalbuminuria is indicated where there is an albumin:creatinine ratio ≥ 2.5 mg/mmol (men) or 3.5 mg/mmol (women). Proteinuria is indicated by a ratio of ≥ 30 mg/mmol.

[Q: 724] OnExamination -
Endocrinology

A 23-year-old woman with type 1 diabetes of three years duration, presents for annual review with weight loss. She had normal menstrual cycles and bowel habit was unchanged. On examination her BMI was 23 kg/m² and investigations revealed a haemoglobin of 7 g/dl and a MCV of 69 fl.

Which of the following is the most likely diagnosis?

- 1- anorexia nervosa
- 2- beta-thalassaemia minor
- 3- Bacterial overgrowth
- 4- coeliac disease
- 5- Crohn's disease

Answer & CommentsAnswer: 4- coeliac disease

Coeliac disease is the likely option as this patient has autoimmune disease (T1DM), an iron deficiency anaemia and little in the way of symptoms. Bacterial overgrowth is associated with profuse diarrhoea and a macrocytosis due to vit B12 consumption. Crohn's disease again would be expected to be symptomatic.

[Q: 725] OnExamination -
Endocrinology

A 17-year-old type 1 diabetic presents for annual review. He takes three times daily short acting insulin with evening dose long acting insulin. His glycaemic control is good as reflected by an HbA1c of 6.5%. He seeks advice regarding his ability to pursue a future career.

Which one of the following occupations would he be able to pursue?

- 1- A chef in the army catering corps
- 2- A steward on board a cruise liner
- 3- A oil rig engineer
- 4- A police officer
- 5- An airline steward

Answer & CommentsAnswer: 5- An airline steward

Careers opportunities are affected by insulin use in Diabetes Mellitus and it is important to know these restrictions in order that you can provide appropriate advice to your patient. Any employment in the armed forces, fire service or police force is not permissible unless already a member of the armed forces. Offshore work again is not an option.

[Q: 726] OnExamination -
Endocrinology

You are consulted by a 52-year-old man with type 2 diabetes diagnosed for 1 year. His blood pressure is 156/88 mmHg, his cholesterol is 5.3mmol/l, he has a BMI of 29 and does not smoke. His HbA1c is 7.9%, he currently takes only Metformin 500mg bd.

The single intervention most likely to reduce his overall risk of microvascular and macrovascular events is:

- 1- Statin therapy
- 2- Sulphonylurea therapy
- 3- Antihypertensive therapy
- 4- Weight reduction
- 5- Aspirin therapy

Answer & Comments

Answer: 3- Antihypertensive therapy

The UKPDS showed that effective antihypertensive therapy reduced the risk of cardiovascular events and microvascular complications. Lowering HbA1c only resulted in a significant reduction in microvascular events. Lipid lowering therapy benefits patients with diabetes as much as those without diabetes in preventing macrovascular events in sub group analyses but has no effect on microvascular events demonstrated so far. Aspirin is recommended to type 2 patients with one other cardiovascular risk factor but there is little trial evidence of efficacy. Weight reduction may reduce progression to overt diabetes from states of impaired glucose tolerance but has not been demonstrated to reduce microvascular risk in diabetes.

[Q: 727] OnExamination -
Endocrinology

A 45-year-old male presents concerned about his risk of developing diabetes. His family history reveals that his mother and maternal uncle are both diabetic. On examination, his

blood pressure is 130/82 mmHg, his BMI is 30.8 kg/m². His investigations reveal:

Fasting cholesterol	5.2 mmol/l (<5.2)
Triglycerides	1.4 mmol/l (0.8-1.5)
HDL cholesterol	1.0 mmol/l (0.9-1.4)
Fasting glucose	6.2 mmol/l (3.5-6)

Which of this man's observations fulfills the criteria for the diagnosis of the metabolic syndrome?

- 1- Blood pressure of 130/82 mmHg
- 2- BMI of 30.2 kg/m²
- 3- Fasting plasma glucose of 6.2 mmol/l
- 4- HDL concentration of 1 mmol/l
- 5- Triglyceride concentration of 1.4 mmol/l

Answer & Comments

Answer: 3- Fasting plasma glucose of 6.2 mmol/l

The metabolic syndrome is becoming hugely important as a cluster of feature associated with increased cardiovascular and diabetes risk. The condition is defined by the NCEP-ATP III criteria as any three of the following features:

- " Waist circumference >102cm male; >96cm female
- " Hypertriglyceridaemia >1.7 mmol/l
- " Low HDL concentration <1.03 mmol/l male, <1.3 mmol/l female
- " BP > or = 130/85 mmHg
- " Fasting glucose > or = 6.1 mmol/l

Thus, in our patients case the elevated fasting glucose of 6.3 mmol/l fulfills this diagnostic criterion. The BMI is not a function of the diagnostic criterion as the waist circumference appear to be a far more powerful predictor of risk.

[Q: 728] OnExamination -
Endocrinology

A 75-year-old man is admitted with a blood sugar of 40 mmol/l and lobar pneumonia and dies despite treatment. Post-mortem examination reports the presence of amyloid polypeptide on pancreatic histology.

This would suggest

- 1- that he has type 2 diabetes
- 2- that he has type 1 diabetes
- 3- that he has diabetes secondary to amyloidosis
- 4- that he has chronic pancreatitis as a cause of diabetes
- 5- this can be a non-specific finding

Answer & Comments

Answer: 1- that he has type 2 diabetes

The presence of amyloid polypeptide on pancreatic histology is highly suggestive of type 2 diabetes. Although the primary defect in type 2 diabetes is insulin resistance, loss of insulin secretory function over time does occur in type 2 diabetic patients, and reduction in beta cell mass due to amyloid deposition may partly account for this.

[Q: 729] OnExamination -
Endocrinology

A 54 year-old male presents with progressive pins and needles and numbness in both feet which have deteriorated over the last six months. He has a 10 year history of Type 2 diabetes mellitus and had cervical spondylosis for which he underwent surgery 8 years ago. He also confessed to drinking approximately 40 units of alcohol weekly.

On examination he had a mild bilateral weakness of foot dorsiflexion, both ankle reflexes were absent and plantar responses were flexor. There was absent sensation to light touch to mid-shin level with loss of joint

position sensation in the toes and absent vibration sensation below the hips. He had a marked sensory ataxia and pseudoathetosis of upper limbs. He had no evidence of a retinopathy and urinalysis was normal.

What is the most likely diagnosis?

- 1- Alcohol-induced neuropathy
- 2- Central lumbar disc prolapse
- 3- Cervical cord compression
- 4- Diabetic peripheral neuropathy
- 5- Vitamin B₁₂ deficiency

Answer & Comments

Answer: 5- Vitamin B₁₂ deficiency

Diabetic peripheral neuropathy usually goes in parallel with retinopathy and nephropathy. It is also slowly progressive and affects mainly spinothalamic pathway. Alcohol induced peripheral neuropathy is also slowly progressive and affects mainly spinothalamic pathway. Vitamin B₁₂ deficiency usually causes a more rapidly progressive neuropathy with dorsal column involvement (joint position and vibration involvement with sensory ataxia and pseudoathetosis of upper limbs).

[Q: 730] OnExamination -
Endocrinology

A 49-year-old male attends regarding a concern over the future development of obesity. He has read on the internet about the metabolic syndrome and its association with diabetes. He wonders if he has this diagnosis.

Which of the following is a specific criteria in the diagnosis of the metabolic syndrome?

- 1- A body mass index of 32 kg/m²
- 2- A family history of type 2 diabetes
- 3- A fasting plasma glucose of 5.9 mmol/l (NR 3.5-6)
- 4- A total cholesterol of 6.2 mmol/l (NR less than 6)

5- A waist circumference of 104 cm (41 inches)

Answer & Comments

Answer: 5- A waist circumference of 104 cm (41 inches)

The metabolic syndrome has been defined as the possession of any three of the following five criteria: A blood pressure above 130/85; HDL less than 1 mmol/l males, 1.3 mmol/l females; triglycerides above 1.7 mmol/l; fasting plasma glucose above 6.1 mmol/l and waist circumference above 88cm females and 102 cm males. The importance of the metabolic syndrome is in its associated morbidity, with a 4x increased risk of developing diabetes and a two fold risk of developing ischaemic heart disease. Central obesity is more highly correlated with the metabolic risk factors than body mass index (BMI) and therefore measurement of waist circumference is recommended to identify the bodyweight component of metabolic syndrome.

[Q: 731] OnExamination - Endocrinology

Which of the following is a metabolic effect of exenatide?

- 1- accelerates gastric emptying
- 2- improves insulin sensitivity
- 3- inhibits insulin release
- 4- promotes gluconeogenesis by the liver
- 5- suppresses appetite

Answer & Comments

Answer: 5- suppresses appetite

Exenatide mimics the effect of the gut hormone GLP-1 (Glucagon-like peptide 1) and has favourable effects on the metabolism of individuals with diabetes mellitus. Exenatide suppresses appetite, inhibits glucose production in the liver, slows gastric emptying

and stimulates insulin release. It does not increase insulin sensitivity which is achieved by drugs such as metformin and the glitazones.

In summary Exenatide has the following metabolic effects

- Stimulates insulin release
- Inhibits glucose production by the liver
- Slows gastric emptying
- Suppresses appetite

Diabetes Care 27:2628-2635, 2004

[Q: 732] OnExamination - Endocrinology

According to the new revised criteria for diagnosing diabetes in an asymptomatic patient

- 1- A single fasting venous plasma glucose concentration of > 7 mmol/l can be used to diagnose diabetes
- 2- Two separate fasting venous plasma glucose concentration of > 7 mmol/l is diagnostic of diabetes
- 3- 75 gm oral glucose test is mandatory for diagnosing diabetes
- 4- A fasting venous plasma concentration of < 6.9 can be ignored
- 5- Impaired glucose tolerance is signified by a venous glucose concentration of ?7 mmol and > 11.1 mmol

Answer & Comments

Answer: 2- Two separate fasting venous plasma glucose concentration of > 7 mmol/l is diagnostic of diabetes

In an asymptomatic individual, a single sample alone is not sufficient for diagnosis. Diabetes can be diagnosed if separate fasting samples show above 7 mmol/l. 75 gram OGT is still the gold standard for diagnosing diabetes,

although fasting glucose can be used, provided adequate fast is ensured. Fasting glucose of above 6.1 but below 6.9 is classed as Impaired Fasting Glycaemia, which is a new category of glycaemia. IGT = 7.8 - 11.1

[Q: 733] OnExamination - Endocrinology

A 52-year-old man with a history of diabetes mellitus presented with hepatomegaly.

Investigations revealed:

Albumin 30 g/L (35-45)

Total bilirubin 22 umol/L (10-22)

Alkaline Phosphatase 134 iU/L (50-110)

ALT 90 iU/L (10-40)

gamma-glutamyl transferase 125 iU/L (10-50)

Ferritin 1450 microg/L (15-400)

Which of the following features would be most suggestive of a diagnosis of haemochromatosis?

- 1- Chondrocalcinosis
- 2- Gynaecomastia
- 3- Migratory polyarthritisd myxoedema
- 4- Myxoedema
- 5- Rash

Answer & Comments

Answer: 1- Chondrocalcinosis

This diabetic male has evidence of liver disease with grossly elevated Ferritin suggesting a diagnosis of Haemochromatosis. A non-migratory polyarthritisd would be suggestive although an oligoarthritis particularly of the hands and hip is more typical. Skin pigmentation rather than a rash is more typical. Myxoedema is not a feature of haemochromatosis. Gynaecomastia is a feature of liver disease/cirrhosis per se and not just haemochromatosis. However, chondrocalcinosis together with the chronic

arthropathy is well recognized in association with haemochromatosis.

[Q: 734] OnExamination - Endocrinology

An 85-year-old woman with diabetes mellitus presented with sudden onset of wild flinging movements of the left arm which disappeared during sleep.

What is the most likely explanation?

- 1- Contralateral subthalamic nucleus infarction
- 2- Focal motor seizures
- 3- Hypoglycaemia
- 4- Ipsilateral caudate nucleus infarction
- 5- Ipsilateral cerebellar infarction

Answer & Comments

Answer: 1- Contralateral subthalamic nucleus infarction

This is hemiballismus, and in a diabetic patient is likely to be due to a vascular event in the contralateral subthalamic nucleus.

[Q: 735] OnExamination - Endocrinology

A 56-year-old female is noted to have hepatomegaly. Six years ago she was diagnosed with diabetes mellitus and takes metformin 500 mg tds and gliclazide 80mg bd. She drinks approximately 15 units of alcohol weekly and stopped smoking 10 years ago.

On examination she has a BMI of 36.2 kg/m, no stigmata of liver disease are evident but she has 6 cm hepatomegaly.

Investigations reveal:

Total bilirubin 11 umol/L (NR 1 - 22)

Alkaline phosphatase 145 IU/L (NR 45 - 105)

AST 100 IU/L (NR 1 - 31)

ALT 150 IU/L (NR 5 - 35)
 Albumin 40 g/L (NR 37 - 49)
 Ferritin 434 mg/L (NR 15 - 300)

Ultrasound of the abdomen reveals an echobright appearance of the liver and gallstones in the gallbladder.

What is the most cause of her liver disease?

- 1- Alcoholic liver disease
- 2- Drug induced hepatitis
- 3- Gallstone disease
- 4- Haemochromatosis
- 5- Non-alcoholic steatohepatitis (NASH)

Answer & Comments

Answer: 5- Non-alcoholic steatohepatitis (NASH)

The patient has a hepatic picture in contrast to Cholestasis. Ferritin level is not too high to be considered for haemochromatosis and is an acute phase reactant being typically increased in any inflammatory process. NASH is very common and is typically encountered in Obese patients, presenting with a hepatic picture with or without jaundice. Echo bright liver suggests fatty change in the liver seen in NASH. It was previously termed Idiopathic decompensated hepatitis and if not treated in terms of lowering BMI and reducing fat intake can lead onto irreversible cirrhosis. Gallstones are a distraction in this history.

[Q: 736] OnExamination - Endocrinology

A 57-year-old man attends the outpatient clinic. He has been a type 2 diabetic for 7 years having been diagnosed following after an acute myocardial infarction at 50 years of age. His diabetic was deteriorating with blood glucose readings of 9-12 at home despite following a diet and taking regular exercise. Another practitioner commenced him on Rosiglitazone. His current treatment is

Metformin 850tds, Rosiglitazone 4mg, Aspirin 75mg/day, Carvedilol 12.5mg bd, Ramipril 10mg od, Furosemide 80mg daily, Simvastatin 40mg/day. On examination he is overweight with a BMI of 29, his BP is 128/74mmHg with pulse rate of 63min⁻¹ he has no heart murmurs there is some pitting oedema in the lower limbs. Auscultation reveals a clear chest with no evidence of pulmonary oedema. He is obese with no organomegaly.

His ECG shows sinus rhythm with poor r wave progression.

His HbA1c checked in the clinic is 8.5%.

What is the most appropriate way to treat his glycaemic control.

- 1- Add Gliclazide 80mg bd
- 2- Increase Rosiglitazone to 8mg daily
- 3- Stop metformin and use Avandamet (combination of Metformin & Rosiglitazone)
- 4- Substitute Rosiglitazone with Pioglitazone 15mg daily
- 5- Substitute Rosiglitazone with Glilazide 80mg bd

Answer & Comments

Answer: 5- Substitute Rosiglitazone with Glilazide 80mg bd

This patient is likely to be insulin resistant however there is evidence of heart failure and fluid overload, so use of a thiazolidinediones (Rosiglitazone or Pioglitazone) is absolutely contraindicated. These drugs promote fluid retention by means of an action on the collecting ducts of the kidney so promoting sodium and water retention. The only appropriate action therefore is to stop Rosiglitazone, substituting this with the insulin secreatagogue gliclazide will hopefully improve his glycaemic control.

[Q: 737] OnExamination -
Endocrinology

A 40-year-old diabetic presents with deteriorating thirst and nocturia. He has been diagnosed with diabetes mellitus 5 years ago and is now taking maximal Metformin and Gliclazide yet his HbA1c is 10.9%. You want to change him to insulin but he informs you that he is employed as a lorry driver.

What would be the impact of converting him to insulin on his Heavy Goods Vehicle licence?

- 1- Can keep his HGV licence
- 2- Can regain his HGV licence if after six months he does not have any hypoglycaemic episodes
- 3- Can regain his HGV licence after one year without hypoglycaemic episodes
- 4- Temporary suspension of his HGV licence until established on stable doses of insulin
- 5- Will lose his HGV licence indefinitely whilst treated with insulin

Answer & Comments

Answer: 5- Will lose his HGV licence indefinitely whilst treated with insulin

Switching patients to insulin does have a major impact on their ability to pursue certain careers and/or vehicle licensing. Insulin treated diabetics are unable to hold a HGV or PSV licence and in some councils are unable to have a taxi licence. For further reading on employment restrictions an diabetes read

[Q: 738] OnExamination -
Endocrinology

An overweight, 60-year-old female with an 8 year history of type 2 diabetes mellitus presents with deteriorating glycaemic control. She takes gliclazide 160 mg twice daily.

Investigations reveal:

Sodium and potassium normal

serum urea 10 mmol/L (2.5 - 7.5)

serum creatinine 160 μ mol/L (60 - 110)

serum alanine transaminase 31 U/L (5 - 35)

serum aspartate transferase 30 U/L (1 - 31)

HbA1C 9.0% (3.8 - 6.4)

Which of the following would be most appropriate additional therapy for improved glycaemic control?

- 1- Acarbose
- 2- guar gum
- 3- metformin
- 4- repaglinide
- 5- rosiglitazone

Answer & Comments

Answer: 5- rosiglitazone

This diabetic has poor glycaemic control with renal impairment. With creatinine concentrations above 150 mmol/L, metformin is not recommended due to the small risk of lactic acidosis. Therefore, the most appropriate treatment as recommended by NICE would be rosiglitazone as LFTs are normal and there is no suggestion of heart failure. Acarbose is poorly tolerated and is now rarely prescribed. Guar gum has little place in the treatment of diabetes. Repaglinide the non-sulphonylurea insulin secretagogue would have little benefit in conjunction with a traditional SU such as Gliclazide.

[Q: 739] OnExamination -
Endocrinology

A 26-year-old male with a three year history of type 1 diabetes presents with fever, vomiting and is dehydrated. He has a sodium concentration of 148 mmol/L, a potassium of 3.3 mmol/L, a urea of 24 mmol/L, a glucose of 33 mmol/L and a pH of 7.18.

What would be the typical total body water deficit associated with his diabetic ketoacidosis?

- 1- 1 litre
- 2- 3 litres
- 3- 6 litres
- 4- 8 litres
- 5- 10 litres

Answer & Comments

Answer: 3- 6 litres

The typical fluid deficit associated with DKA is approximately 6 litres. The initial half of this amount is derived from intracellular fluid and precedes signs of dehydration, while the other half is from extracellular fluid and is responsible for clinical signs of dehydration. Appropriate fluid replacement requires 1 litre of Normal saline over the first 1/2 hour, then 1 litre over the next hour, then 1 litre over the next two hours followed by 1 litre every 4 hours depending on the degree of dehydration.

[Q: 740] OnExamination - Endocrinology

A 33-year-old type 1 diabetic male presents with a two day history of pain, swelling and redness in his left middle finger. This began after he pricked his finger in the garden whilst pruning a bush. His diabetic control has been quite reasonable with a HbA1c of 7.1% on basal bolus insulin consisting of Lispro tds and Humulin I in the evenings. On examination he has a painful, red and swollen middle finger with the redness extending to the metacarpophalangeal joint. He is diagnosed with cellulites.

What is the most appropriate treatment for this patient?

- 1- Admit to hospital for IV antibiotics
- 2- Oral flucloxacillin only
- 3- Oral metronidazole only
- 4- Oral penicillin V only
- 5- Oral penicillin V and flucloxacillin

Answer & Comments

Answer: 5- Oral penicillin V and flucloxacillin

The patient has digital cellulitis and the most likely organisms responsible are *Strep pyogenes* or *Staphylococcus aureus*. The most appropriate treatment is penicillin V and Flucloxacillin which should result in a rapid improvement. If there is a deterioration then admission for IV antibiotics may be required but this should be unnecessary with appropriate antibiotic selection.

[Q: 741] OnExamination - Endocrinology

A 35 year-old woman with type 1 diabetes mellitus presents for annual assessment.

Which one of the following features on fundoscopy would require urgent referral to an ophthalmologist?

- 1- asteroid bodies
- 2- hard exudates in the macular region
- 3- intraretinal microvascular abnormalities
- 4- scattered microaneurysms
- 5- soft exudates

Answer & Comments

Answer: 2- hard exudates in the macular region

Scattered microaneurysms signify background DRn. IRMAs and soft exudates signify pre-proliferative retinopathy. According to the NleH, urgent referral to an ophthalmologist (seen within one week) is required if there is proliferative retinopathy or there is evidence of clinically significant macular oedema (hard exudates at the fovea).

[Q: 742] OnExamination -
Endocrinology

An asymptomatic 56-year-old man with a family history of type 2 diabetes was found to have a fasting venous glucose of 6.5 mmol/l.

Which of the following relating to his further investigation is correct?

- 1- He has impaired glucose tolerance
- 2- This does not need further investigation
- 3- He should be investigated further by another fasting venous sampling
- 4- He should undergo a 75 gm oral glucose tolerance test.
- 5- He should be treated with oral hypoglycaemics in the first instance

Answer & Comments

Answer: 4- He should undergo a 75 gm oral glucose tolerance test.

According to the new revised criteria for the diagnosis of diabetes, venous plasma glucose (VPG) of 6.1 - 6.9 is categorised as Impaired Fasting Glycaemia and requires further assessment with a 75 gram oral glucose tolerance test (OGT) which is still the gold standard. A 2 hour value of equal to or over 11.1 mmol/l is diagnostic of diabetes. Impaired glucose tolerance is a 2 hour VPG of 7.8 - 11.1 during an OGT. Initial treatment of type 2 diabetes is patient education, diet and lifestyle changes

[Q: 743] OnExamination -
Endocrinology

To which of the following drug classes do the oral hypoglycaemic agents, Rosiglitazone and Pioglitazone belong?

- 1- A Peroxisome Proliferator Activating Receptor (PPAR)-alpha agonist
- 2- A Peroxisome Proliferator Activating Receptor (PPAR)-gamma agonist
- 3- A Sulphonylurea

4- A Biguanide

5- An alpha-Glucosidase inhibitor

Answer & Comments

Answer: 2- A Peroxisome Proliferator Activating Receptor (PPAR)-gamma agonist

Rosi- and Pio- glitazone belong to a new class of oral hypoglycaemic agents - PPAR gamma agonists. Through activation of this receptor they modulate adipocyte function and improves insulin sensitivity.

[Q: 744] OnExamination -
Endocrinology

A 37-year-old female with type 2 diabetes and obesity requests help with regard to weight loss. She has tried to lose weight with dietary manoeuvres but has succeeded in losing only 3kg over the last year. She is currently receiving no treatment. On examination her BMI is 33.5 kg/m² and her blood pressure is 142/84 mmHg. Her most recent HbA1c is 6.9%. She asks whether there are any pharmacological therapies that may be appropriate for assisting with weight reduction.

Which of the following agents is appropriate for assisting with weight loss in this patient?

- 1- Dexfenfluramine
- 2- Metformin
- 3- Orlistat (Xenical)
- 4- Phentermine
- 5- Sibutramine (Reductil)

Answer & Comments

Answer: 3- Orlistat (Xenical)

This patient has demonstrated a 3kg weight loss over the past year but like many has become rather stuck. The NICE criteria for Orlistat previously stated it should be used in patients who have demonstrated dietary

compliance with at least a 2.5 kg weight reduction prior to initiating Orlistat. This is not now a requirement. Continued weight reduction is required if the patient is to remain on the drug (5% body weight at 12 weeks). Orlistat functions through inhibiting the absorption of dietary fat from the GI tract. Consequently, its side effects include flatulence and diarrhoea. Dexfenfluramine is associated with systemic hypertension and strokes and is now withdrawn as an anti-obesity agent, as is phentermine (valvular fibrosis) in the successful but dangerous combination Phen-Fen. Metformin is not an agent that would create weight loss but merely improves insulin sensitivity and maintain rather than lose weight (or gain weight as in sulphonylurea therapy). Similarly this patient's HbA1c is well controlled on diet alone. Sibutramine is another licensed drug for the treatment of obesity but is contraindicated in hypertension as it may be associated with increased BP. Consequently NICE recommend monitoring BP during treatment.

[Q: 745] OnExamination - Endocrinology

A 63 year female with a 12 year history of hypertension and diabetes has been treated with metformin 1g bd, Gliclazide 80 mg bd, Rosuvastatin 10mg daily, Ramipril 10 mg daily, aspirin 75 mg daily and amlodipine 10 mg daily for the last two years. At annual review her blood pressure is 138/82 mmHg, fundi reveal background diabetic retinopathy, foot pulses are normal but she has evidence of a peripheral sensory loss to the ankles in both feet. Her results show a HbA1c of 7.2% (NR <6.5), a urea of 12.5 mmol/l (NR 3-7), creatinine of 176 micromol/l and cholesterol of 4.8 mmol/l.

Which of the following drugs should be withdrawn?

1- Aspirin

- 2- Gliclazide
- 3- Metformin
- 4- Ramipril
- 5- Rosuvastatin

Answer & Comments

Answer: 3- Metformin

This patient has evidence of chronic renal impairment with elevated creatinine and urea. Guidelines currently suggest that metformin should be stopped if creatinine is above 150 micromol/l. The estimated prevalence of life-threatening lactic acidosis is one to five cases per 100 000, with mortality in reported cases up to 50%. Traditionally, this complication has been thought of as secondary to an accumulation of the drug. Metformin is excreted unchanged in the urine, with the half-life prolonged and renal clearance decreased in proportion to any decrease in creatinine clearance. This may occur chronically in chronic renal impairment, or acutely with dehydration, shock, and intravascular administration of iodinated contrast agents, all of which have the potential to alter renal function. Tissue hypoxia also has a significant role, and acute or chronic conditions that may predispose to this condition, such as sepsis, acute myocardial infarction, pulmonary embolism, cardiac failure and chronic liver disease, may act as triggers. As the patient appears to have chronic renal impairment and as she has been on ramipril for a considerable period it is unlikely that she has renal artery stenosis requiring the withdrawal of the ACEi.

[Q: 746] OnExamination - Endocrinology

A 60-year-old male who was previously fit and well presented with a six week history of blurring of vision. His investigation revealed a fasting plasma glucose of 12.9 mmol/L (3.0 - 6.0).

What is the most likely cause of his blurred vision?

- 1- Cataract
- 2- Maculopathy
- 3- Osmotic changes in the lens
- 4- Proliferative diabetic retinopathy
- 5- Retinal vein thrombosis

Answer & Comments

Answer: 3- Osmotic changes in the lens

Without being given too much here, this patient is a newly diagnosed diabetic as we are told he was previously fit and well. Therefore the most probable explanation for his blurred vision is osmotic changes.

[Q: 747] OnExamination - Endocrinology

An 18-year-old man develops thirst, weight loss and polyuria. Investigations confirm that he has type 1 diabetes and is treated with basal bolus insulin. He is keen to know what limitations this diagnosis imposes on career opportunities.

Which of the following professions would he not be able to pursue?

- 1- Ambulance control centre worker
- 2- Civil engineer
- 3- Milkman
- 4- Physical Education instructor
- 5- Policeman

Answer & Comments

Answer: 5- Policeman

The armed forces, working offshore or aboard ships, air pilot, HGV/PSV licence, Police, Fire or driving in the post office are career paths closed to subjects with insulin dependent diabetes. Some local authorities do permit

licences to taxi drivers with insulin treated diabetes whilst others do not.

[Q: 748] OnExamination - Endocrinology

With respect to lipoprotein transport and metabolism in the body, the following statements are correct EXCEPT:

- 1- Arterial walls contain cells with LDL receptors.
- 2- Cholesterol is required for the formation of red blood cell membranes.
- 3- Chylomicrons are synthesized in the liver.
- 4- HDL is assembled in the extracellular space.
- 5- VLDL transformation to LDL occurs in adipose tissue.

Answer & Comments

Answer: 3- Chylomicrons are synthesized in the liver.

Chylomicrons are formed in the gut from exogenous triacylglycerols and cholesterol. They are released into the lymph and thereby enter the blood. They are not formed in the liver.

[Q: 749] OnExamination - Endocrinology

A 45-year-old man presents with an ulcer on his right foot. He has a twenty year history of type 1 diabetes and currently uses mixed insulin twice daily. On examination he has a small ulcer of approximately 2 cm diameter on the outer aspect of his right big toe. His peripheral pulses are all palpable but he has a peripheral neuropathy to the mid shins. The ulcer has an erythematous margin and is covered by pus.

What is the most likely infective organism?

- 1- Escherichia coli
- 2- MRSA

- 3- Pseudomonas aeruginosa
- 4- Staphylococcus aureus
- 5- Streptococcus pyogenes

Answer & Comments

Answer: 4- Staphylococcus aureus

Although the infective organism in diabetic foot ulcers are usually mixed, the most likely infective organism in this case is Staphylococcus aureus. MRSA would be less likely but might be suspected if the patient developed an infection in hospital or had recurrent admissions. The most appropriate antibiotic therapy is Flucloxacillin plus another broad spectrum agent with advice that the patient should not wear weight bearing and wear appropriate footwear.

[Q: 750] OnExamination - Endocrinology

A 42-year-old male presents with polyuria and polydipsia. He is a non-smoker and drinks approximately 12 units per week. He is employed as a taxi driver. On examination he has a BMI of 33.4 kg/m², a blood pressure of 132/82 mmHg with all other aspects of the cardiovascular examination normal. Investigations confirm a diagnosis of diabetes mellitus with a fasting blood glucose concentration of 12.1 mmol/l. His HbA1c is 9% and total cholesterol is 5.8 mmol/l.

What is the most appropriate initial treatment for this patient?

- 1- Diet and lifestyle advice
- 2- Gliclazide
- 3- Metformin
- 4- Orlistat
- 5- Simvastatin

Answer & Comments

Answer: 1- Diet and lifestyle advice

This patient who has typical type 2 diabetes, which should initially be treated with diet and lifestyle advice - appropriate dietary advice and exercise programme to endeavour to achieve weight loss. He should receive at least three months of this intervention before re-assessing and considering pharmacological intervention if the lifestyle approaches are not succeeding. If this is the case then the drug of choice would be metformin.

[Q: 751] OnExamination - Endocrinology

A 42-year-old man being investigated for diabetes and impotence is noted to have the following results:

Alanine aminotransferase 30 U/L (5-35)
 Aspartate aminotransferase 22 U/L (1-31)
 Fasting plasma glucose 7.4 mmol/L (3.0-6.0)
 Ferritin 500 ug/L (15-300)

Which one of the following would be the next most appropriate investigation?

- 1- bone marrow smear and iron stain
- 2- liver biopsy
- 3- red cell protoporphyrins
- 4- serum transferrin receptors
- 5- transferrin saturation

Answer & Comments

Answer: 5- transferrin saturation

This patient has a suspected diagnosis of haemochromatosis as suggested by the presentation and laboratory investigations including elevated ferritin. The next investigation would be measurement of transferrin saturation and then if elevated (above 45%) genotyping (Homozygosity for C282y mutations) would next be considered and would be expected to clinch the diagnosis. In the event of rarer mutations confirmation with liver biopsy may be required.

[Q: 752] OnExamination -
Endocrinology

A 30-year-old lady with long standing Type I diabetes presents with a 3 month history of pain and stiffness of the right shoulder. Passive and active movements of the shoulder are equally restricted.

What is the most likely diagnosis?

- 1- Rheumatoid arthritis
- 2- Osteoarthritis
- 3- Calcific tendinitis
- 4- Pyrophosphate arthropathy (pseudogout)
- 5- Adhesive capsulitis

Answer & Comments

Answer: 5- Adhesive capsulitis

Adhesive capsulitis (frozen shoulder) is strongly associated with diabetes with as many as 40% of patients developing this problem at some stage. The restricted active and passive movements confirm that this patient's problems are either capsular or articular in origin rather than periarticular tendon problems where active movements are generally more restricted than passive movements. The shoulder joint is rarely affected by primary osteoarthritis.

[Q: 753] OnExamination -
Endocrinology

A 35-year-old woman is noted to have ++ glycosuria by his GP. Her BMI is 35 kg/m² (18-25) and a fasting plasma glucose is 7.4 mmol/L (3.0-6.0).

Which one of the following measures would be most effective in reducing her insulin resistance?

- 1- Glibenclamide
- 2- Insulin
- 3- Metformin
- 4- Weight loss

5- Repaglinide

Answer & Comments

Answer: 4- Weight loss

The most appropriate treatment of this obese type 2 diabetic female which would also substantially reduce insulin concentrations is weight loss. Glibenclamide may be associated with increased insulin resistance as it stimulates insulin secretion, as does repaglinide. Metformin would improve insulin sensitivity but would not do it as much as weight loss. The unfortunate thing is that weight loss is the most difficult strategy for the patient to adhere to. Its much easier to take a pill than to diet.

[Q: 754] OnExamination -
Endocrinology

Inhaled insulin is approved for the treatment of diabetes.

In which of the following should inhaled insulin be avoided?

- 1- Autoimmune disease
- 2- Depression
- 3- Obesity
- 4- Peripheral vascular disease
- 5- Smokers

Answer & Comments

Answer: 5- Smokers

Exubera is the first licensed inhaled insulin. It is a fast acting insulin and studies reveal that it is as effective as subcutaneous insulin in both type 1 and type 2 diabetes. As a consequence of increased absorption and precipitation of hypoglycaemia, it is not recommended in smokers.

[Q: 755] OnExamination -
Endocrinology

A 55-year-old obese man with Type 2 Diabetes Mellitus is uncontrolled on diet alone.

Which antidiabetic therapy would increase insulin sensitivity in this patient?

- 1- Acarbose
- 2- Gliclazide
- 3- Glimiperide
- 4- Repaglinide
- 5- Rosiglitazone

Answer & Comments

Answer: 5- Rosiglitazone

Of the drugs listed only rosiglitazone would boost insulin sensitivity. Other thiazolidinediones such as pioglitazone would also do this as well as the more widely prescribed metformin!

Gliclazide, glimiperide and repaglinide are insulin secretagogues - they boost insulin secretion. Acarbose has a modest effect on the absorption of sugars from the gut but its main effect is to cause flatulence.

Type 2 Diabetes is due to two defects - insulin resistance and insulin deficiency. In 95% of patients it is insulin resistance that is the main cause of the diabetes. These patients are typically obese with features of the metabolic syndrome. The bulk of the insulin resistance appears to be in skeletal muscle. The state of insulin resistance is associated with abnormal glucose metabolism (obviously) and excessive free fatty acids in the blood. Drugs and lifestyle modifications that increase insulin sensitivity (and thereby reduce insulin resistance) help to reverse these abnormalities.

[Q: 756] OnExamination -
Endocrinology

A 44-year-old woman with type 1 diabetes mellitus has not attended the diabetic clinic for 5 years. Examination shows no abnormalities.

Investigations show:

Haemoglobin 9 g/dL

MCV 94 fL

Haematocrit 28%

HbA1c 10.1%

A blood smear shows normochromic, normocytic anaemia

Which of the following is the most likely cause?

- 1- acute blood loss
- 2- chronic lymphocytic leukaemia
- 3- erythropoietin deficiency
- 4- microangiopathic haemolysis
- 5- sideroblastic anaemia

Answer & Comments

Answer: 3- erythropoietin deficiency

The most likely cause is progressive renal failure which leads to reduced release of erythropoietin from the kidneys. Sideroblastic anaemia (myelodysplasia) is seen in older age groups. CLL or microangiopathic haemolysis are possible causes but unlikely.

[Q: 757] OnExamination -
Endocrinology

A 33-year-old woman with an eighteen year history of type I diabetes mellitus presents with proteinuria. She is a smoker of 20 cigarettes daily. Examination reveals a blood pressure of 155/95 mmHg. Investigations reveal:

serum cholesterol 7.6 mmol/L (<5.2)

HbA1c 8.3% (3.8 - 6.4)

24 hour urinary protein excretion 1.5 g (< 0.2)

Which intervention is most likely to retard the development of renal failure?

- 1- bendroflumethiazide
- 2- improve glycaemic control with HbA1c <7%
- 3- lisinopril
- 4- simvastatin
- 5- stop smoking

Answer & Comments

Answer: 3- lisinopril

This patient has diabetic nephropathy with marked proteinuria. To attenuate the progression towards end stage renal disease, stringent blood pressure control should be employed maintaining a BP less than 130/80 and an ACE inhibitor would probably offer even greater reno-protection than any other anti-hypertensive. Simvastatin has no proven benefit on renal disease and improved glycaemic control although of benefit would be of less benefit than BP control (UKPDS/DCCT trials). Again stopping smoking would probably be of greatest benefit to her with regard to reducing cardiovascular risk but would not itself offer any reno-protective effect.

[Q: 758] OnExamination - Endocrinology

A 45-year-old female attends the diabetic annual review clinic. Her body mass index has increased over the year to 33.3.

How do you calculate body mass index?

- 1- Height/Weight
- 2- Height/(Weight) 2
- 3- Weight/Height
- 4- Weight/(Height) 2
- 5- Weight/? Height

Answer & Comments

Answer: 4- Weight/(Height)2

BMI is one of the most important calculations of anthropometry, is calculated as weight over (height) squared and measured in kg/m². BMI can be defined as underweigh (less than 18.5), normal (18.5-24.9), overweight (25-29.9) and obese. A BMI above 30 diagnoses obesity and has prognostic value indicating increased propensity to develop diabetes, cancer, osteoarthritis and depression.

[Q: 759] OnExamination - Endocrinology

A 33-year-old type 1 diabetic male presents with a two day history of pain in his left hand, fever and a rash. This began after he pricked his finger in the garden whilst pruning a bush. His diabetic control has been quite reasonable with a HbA1c of 7.1% on basal bolus insulin consisting of Lispro tds and Humulin I in the evenings. On examination he has a painful, red and swollen middle finger with the redness extending to the metacarpophalangeal joint. He is diagnosed with cellulites and is prescribed antibiotics.

What is the most likely infective organism?

- 1- Escherichia coli
- 2- Klebsiella
- 3- MRSA
- 4- Pseudomonas aeruginosa
- 5- Streptococcus pyogenes

Answer & Comments

Answer: 5- Streptococcus pyogenes

This patient has a community-acquired cellulitis which is most likely due to either strep or Staphylococcus aureus (not MRSA which is more of a hospital pathogen and tends not to cause cellulitis). Understanding the likely infective organism can therefore dictate appropriate antibiotic therapy. In this

case oral flucloxacillin and Pencillin V are appropriate. If the cellulitis does not quickly improve then intravenous antibiotics may be required.

[Q: 760] OnExamination - Endocrinology

A 53-year-old male presents with a 3 month history of polyuria with polydipsia.

Which of the following measurements would confirm a diagnosis of diabetes mellitus?

- 1- A fasting plasma glucose of 6.5 mmol/l
- 2- A fasting plasma glucose of 7.5 mmol/l
- 3- A plasma glucose of 10 mmol/l at the end of an oral glucose tolerance test
- 4- A random glucose of 10.5 mmol/l
- 5- A urine dipstick analysis showing +++ glucose

Answer & Comments

Answer: 2- A fasting plasma glucose of 7.5 mmol/l

Diabetes Mellitus is diagnosed on the basis of symptoms plus a random glucose above 11.1 mmol/l or fasting plasma glucose above 7 mmol/l or the two hour oral glucose tolerance test. Impaired glucose tolerance would be indicated by a post OGTT plasma glucose between 7.7 and 11.1 or a fasting plasma glucose between 6.1 and 7.

[Q: 761] OnExamination - Endocrinology

A 59-year-old woman has had insulin dependent diabetes mellitus for over two decades. The degree of control of her disease is characterized by the laboratory finding of a HbA1c of 10.1%. She complains of repeated episodes of abdominal pain following meals. These episodes have become more frequent and last for longer periods over the last couple of months.

On physical examination, there are no abdominal masses or organomegaly and no tenderness to palpation.

Which of the following findings is most likely to be present?

- 1- Acute pancreatitis
- 2- Chronic renal failure
- 3- Hepatic infarction
- 4- Mesenteric artery occlusion
- 5- Ruptured aortic aneurysm

Answer & Comments

Answer: 4- Mesenteric artery occlusion

Diabetes- especially Type 2 diabetes- is associated with macrovascular disease. Smoking is a further risk factor for macrovascular atherosclerosis. After a meal splanchnic blood flow is increased. If the mesenteric artery is occluded the lack of blood flow to the bowel will produce ischaemic type pain. Chronic renal failure may be present but would not cause post prandial pain. Ruptured aortic aneurysm would normally present acutely with hypotension, cold lower limbs with reduced pulses and a pulsatile, tender abdominal mass. Pancreatitis is unlikely given the history and the lack of epigastric tenderness. Hepatic infarction should lead to right upper quadrant pain.

[Q: 762] OnExamination - Endocrinology

A 17-year-old girl is admitted with a 2 day history of rigors due to a urinary tract infection. On examination she appears unwell, has a Body Mass Index of 31 kg/m², a temperature of 39°C; examination is otherwise normal.

Initial biochemistry revealed:

Potassium 4 mmol/L (3.5-5)

Urea 7 mmol/L (2.5-7)

Glucose 33 mmol/L (3.0-6.0)

pH 7.3 (7.36-7.44)
 Standard bicarbonate 14 mmol/l
 Base deficit -10
 urinalysis negative for ketones

Which one of the following is the best initial treatment for her hyperglycaemia?

- 1- Metformin
- 2- Metformin plus Gliclazide
- 3- Rosiglitazone
- 4- Sliding scale IV insulin infusion
- 5- Subcutaneous insulin mixture

Answer & Comments

Answer: 4- Sliding scale IV insulin infusion

This patient has a metabolic acidosis with pH of 7.3 and low bicarbonate likely due to sepsis. She is likely to be a type 2 diabetic, given the BMI, with uncontrolled hyperglycaemia but is unlikely to have classical diabetic ketoacidosis because the urine is negative for ketones.

It is important that her glycaemia is controlled to promote recovery from the sepsis. This is best achieved with intravenous insulin initially.

[Q: 763] OnExamination - Endocrinology

A 60-year-old lady with dyslipidaemia, hypertension and angina has recently been diagnosed with impaired glucose tolerance. Clinically she is obese with a BMI of 32 kg/m², her blood pressure is 140/80mmHg. She is aware that having impaired glucose tolerance is a risk factor for type 2 diabetes and would like to discuss strategies to attenuate this risk.

Which of the following has been shown to best reduce the incidence of type 2 diabetes in individuals with IGT?

- 1- Acarbose 100mg tds
- 2- Gliclazide
- 3- Intensive lifestyle change

- 4- Metformin 850mg bd
- 5- Pioglitazone 15mg daily

Answer & Comments

Answer: 3- Intensive lifestyle change

Both the diabetes prevention programme (DPP) and Finnish diabetes prevention study showed a 58% reduction in incidence of type 2 diabetes after intervention which involved intensive dietary change, increased physical activity and weight loss.

This compares with a 31% reduction in incidence when metformin was used. Acarbose has also been shown to reduce the incidence of diabetes in combination with lifestyle change when compared with Placebo. There is evidence that the thiazolidinedione Rosiglitazone has been shown to reduce the incidence of type 2 diabetes in individuals with pre diabetes when the Dream study was published in 2006. Currently this is not licensed in the UK for diabetes prevention.

[Q: 764] OnExamination - Endocrinology

A 32-year-old lady presented with episodes of polydipsia and polyuria for the last 6 months.

Investigations:

serum urea 8.1 mmol/L (2.5-7.5)
 serum creatinine 92 mol/L (60-110)
 serum corrected calcium 2.85 mmol/L (2.2-2.6)
 serum phosphate 0.75 mmol/L (0.81-4)
 plasma parathyroid hormone 6.2 pmol/L (0.9-5.4)

Which of the following is directly responsible for his increased reabsorption of calcium in the distal tubule of the kidney?

- 1- 1,25 dihydroxy vitamin D
- 2- 25 hydroxy vitamin D
- 3- calcitonin

4- hypophosphatemia

5- parathyroid hormone

Answer & Comments

Answer: 5- parathyroid hormone

This patient has hypercalcaemia due to hyperparathyroidism. Parathyroid hormone has a number of direct effects: enhancing the release of calcium from bones by binding to osteoblasts which stimulates the formation of osteoclasts, and enhances reabsorption of calcium in the distal tubules.

[Q: 765] OnExamination -
Gastroenterology

A 75-year-old male presents with a two month history of dyspnoea, weight loss and generalised lethargy. Past medical history included a previous left-sided hemiparesis due to stroke for which he took aspirin and perindopril.

Examination revealed residual left sided hemiparesis together with a pale and slightly jaundiced appearance.

Investigations show:

Haemoglobin 5 g/dL (13-16.5)

MCV 109 fL (80-96)

White cell count $2 \times 10^9/L$ (4-11)

Platelets $45 \times 10^9/L$ (150-400)

Urinalysis: Increased urobilinogen

What is the next most appropriate investigation?

- 1- Bone marrow aspirate
- 2- Direct antiglobulin test
- 3- Endoscopy
- 4- Serum haptoglobins
- 5- Vitamin B₁₂ concentration

Answer & Comments

Answer: 5- Vitamin B₁₂ concentration

In this situation, Serum B12 estimation is the correct choice. With a pancytopenic picture and raised MCV, the most appropriate step is to check the B12 and folate. The other choices are considered only after the basic assays. Haemolysis does not explain the low WCC, nor the thrombocytopaenia. A haptoglobin only adds weight to a diagnosis of haemolysis, and a RBC-labelled scan would add greater sensitivity to the diagnosis of haemolysis.

The mild jaundice is typical of megaloblastic anaemia (Vitamin B₁₂ or folate deficiency)

because of increased destruction of red cell precursors in the bone marrow.

[Q: 766] OnExamination -
Gastroenterology

A male teacher who is 31 years of age, attends clinic with his partner who tells you that he has memory problems. The only other symptom is intermittent diarrhoea over the preceding 4 months. He has limited vertical eye movements and exhibits rhythmic simultaneous eye and mouth movements.

Which pathogen is most likely to be the cause of his symptoms?

- 1- Clostridium botulinum
- 2- HIV
- 3- Prion protein
- 4- Salmonella enteritidis
- 5- Tropheryma whippelii

Answer & Comments

Answer: 5- Tropheryma whippelii

This is a tough question. The suggestion here is that the patient has Whipple's disease, due to intestinal infection with Tropheryma Whippelii. Non neurological manifestations of Whipple's disease are more common and include chronic diarrhoea, malabsorption with steatorrhoea and associated abdominal distension and tenderness. Neurological manifestations involve a chronic, progressive, impairment of higher mental function in association with seizures, myoclonus ataxia and oculomasticatory myorhythmia found uniquely in Whipple's. The diagnosis is made by duodenal or jejunal biopsy and demonstrating the bacilli within the mucosa on PAS staining. Characteristically, there is accumulation of glycoprotein and fat filled (PAS +ve) macrophage within the lamina propria. Botulism does not produce this clinical picture. An AIDS related dementia is possible, but abnormal facial movements

would be unusual. CJD could also produce this picture, although myoclonus is usually more of a feature and cognitive impairment is more generalised and acute. Salmonella enteritidis usually causes only an acute diarrhoeal illness, but may lead to bacteraemia and chronic long-term carriage and excretion.

[Q: 767] OnExamination -
Gastroenterology

A 19-year-old student presents with weight loss and blood loss per rectum. You organise a flexible sigmoidoscopy.

Which of the following histological features would favour a diagnosis of Crohn's disease and not ulcerative colitis?

- 1- Crypt abscesses
- 2- Metaplastic polyp formation
- 3- Goblet cell mucus depletion
- 4- Lymphocyte infiltrate of the lamina propria
- 5- Caseating granulomata

Answer & Comments

Answer: 4- Lymphocyte infiltrate of the lamina propria

Ulcerative colitis is characterised by mucosal inflammation with general inflammatory cell infiltration, goblet-cell mucus depletion, crypt abscesses, crypt shortening and branching. There is continuous inflammation, worsening from caecum to rectum. In contrast, Crohn's disease is characterised by transmural inflammation, with neutrophil infiltrates and lymphoid aggregates, fissures, preservation of crypt architecture, and non-caseating granulomata. There is patchy inflammation from mouth to anus.

[Q: 768] OnExamination -
Gastroenterology

A 30-year-old woman presents with jaundice and her investigations reveal:

Haemoglobin 9.0 g/dL (11-16)

reticulocyte count $180 \times 10^9/L$ (25-85)

serum bilirubin 50 $\mu\text{mol/L}$ (1-20)

Her blood film reveals the presence of spherocytes.

Which of the following is the next most useful investigation?

- 1- abdominal ultrasound scan
- 2- direct antiglobulin test
- 3- glucose-6-phosphate dehydrogenase activity
- 4- haemoglobin electrophoresis
- 5- red cell osmotic fragility

Answer & Comments

Answer: 2- direct antiglobulin test

The results given indicate a haemolytic anaemia of which spherocytes are typical and given the age of patient the most likely cause is immune. Therefore the most useful test is the Direct Antiglobulin Test.

[Q: 769] OnExamination -
Gastroenterology

A 30-year-old caucasian male presents with a six month history of weight loss, abdominal pain, and diarrhoea. On examination you note finger clubbing.

Which of the following diagnoses is least likely.

- 1- Crohn's disease
- 2- Ulcerative colitis
- 3- Coeliac disease
- 4- Whipple's disease
- 5- Ileocaecal TB

Answer & Comments

Answer: 5- Ileocaecal TB

Ileo-caecal TB is the only condition mentioned not associated with clubbing and would be very rare in a young caucasian in the UK.

[Q: 770] OnExamination -
Gastroenterology

A 45-year-old woman is diagnosed with a duodenal ulcer.

Which one of the following is the most sensitive test for detecting current infection with Helicobacter pylori?

- 1- A gastric fundal biopsy.
- 2- Culture of a gastric biopsy.
- 3- The (13C) urea breath test.
- 4- The presence of Helicobacter pylori serum antibodies.
- 5- The urease test on gastric biopsy.

Answer & Comments

Answer: 3- The (13C) urea breath test.

The gold standard for diagnosis of H. pylori remains culture of a gastric biopsy. Yet this test is only 72% sensitive. However, the rapid Urease test on a biopsy is 80-95% sensitive and 95-100% specific. Histology is 80-90% sensitive and 95% specific. However, the urease breath test is approximately 95% sensitive and 98-100% specific. Therefore the most specific and clinically applicable would be the urease breath test. The presence of IgG antibodies to H. pylori could indicate previous infection. A gastric antral biopsy can give false negative results following PPI treatment.

[Q: 771] OnExamination -
Gastroenterology

Which of the following is true of Spontaneous bacterial peritonitis?

- 1- A survival rate of over 50% is expected at one year
- 2- Gentamicin is the treatment of choice

- 3- is characteristically caused by aerobic bacteria.
- 4- is diagnosed by culture of ascitic fluid.
- 5- is due to intestinal perforation

Answer & Comments

Answer: 3- is characteristically caused by aerobic bacteria.

SBP is a frequent complication of the ascites of cirrhosis. It is diagnosed by ascitic fluid examination which reveals a PMN count of >250/ml. SBP has poor prognostic significance with a one year survival after a diagnosis of between 30-50%. It is, as the name suggests a spontaneous event that is not a consequence of intestinal perforation. It is speculated that the infective organism may leak into the ascitic fluid via the blood or from intestinal overgrowth. Organisms should be cultured by directly collecting into blood culture bottles. It is typically caused by aerobic Gram negative bacteria. Hence Cefotaxime is regarded as the drug of choice for treatment.

[Q: 772] OnExamination -
Gastroenterology

A 52-year-old male is admitted with vomiting and acute epigastric abdominal pain which radiates through to his back. Investigations confirm severe acute pancreatitis.

Which of the following figures most accurately reflect the mortality associated with severe acute pancreatitis?

- 1- Less than 5%
- 2- Approximately 10%
- 3- Approximately 20%
- 4- Approximately 30%
- 5- Approximately 40%

Answer & Comments

Answer: 3- Approximately 20%

Mortality in acute pancreatitis varies according to age, co-morbidities and severity and is scored through the Ranson scoring system. However, average mortality has remained pretty much unchanged over the last two decades with severe disease and is approximately 20%.

[Q: 773] OnExamination - Gastroenterology

Which of the following is correct regarding infection with Salmonella typhi

- 1- children are particularly likely to become carriers
- 2- most carriers are female
- 3- faecal culture is almost always positive during the first week of illness
- 4- relapse does not occur if antibiotics are taken for 2 weeks
- 5- vaccinated individuals who develop the disease will have a mild illness

Answer & Comments

Answer: 2- most carriers are female

Children are rarely chronic carriers of the organism although for some unknown reason females are more commonly long-term carriers than males (Remember Typhoid Mary).

C-only 50% of cases

E-higher threshold but same disease.

[Q: 774] OnExamination - Gastroenterology

A patient is referred to hepatology department for possible treatment of Hepatitis B. He has stigmata of chronic liver disease. There is portal hypertension and ascites. His INR is 2.2 and albumin 25g/L. HBsAg and HBeAg positive. Hepatitis C screen is negative.

What will you suggest for treatment?

- 1- Beta interferon
- 2- Lumivudine alone
- 3- Lumivudine plus interferon
- 4- Ribavirin alone
- 5- Ribavirin plus interferon

Answer & Comments

Answer: 2- Lumivudine alone

Ribavirin is used for Hepatitis C infection. Its combination with interferon confers more success in treating HCV infection. Interferon cannot be used in this case as it can initially worsen hepatic decompensation. Lumivudine alone is safe in decompensated HBV infection.

[Q: 775] OnExamination - Gastroenterology

Which of the following is true of Gilbert's syndrome?

- 1- inheritance is autosomal dominant
- 2- serum conjugated bilirubin levels are elevated
- 3- serum bilirubin levels are decreased by fasting
- 4- serum bilirubin levels are decreased by liver enzyme inducers
- 5- there is bilirubinuria

Answer & Comments

Answer: 4- serum bilirubin levels are decreased by liver enzyme inducers

Gilbert's syndrome is inherited in autosomal recessive fashion and affects 2-5% of the population. UDP glucuronyl transferase levels are reduced leading to an unconjugated hyperbilirubinaemia.

Whilst serum bilirubin levels are elevated the other LFTs are normal. Jaundice deepens after a period of fasting or intercurrent illness but

bilirubin levels are reduced by enzyme inducers such as phenobarbitone.

As unconjugated bilirubin is tightly bound to albumin it cannot cross the glomerulus and so is not found in the urine. This contrasts with the bilirubin-glucuronide-albumin complex formed in patients with cholestatic jaundice (and raised conjugated bilirubin levels) where 1% of the complex is dialysable and although most of the bilirubin is reabsorbed in the proximal tubule some bilirubin is detectable in the urine.

[Q: 776] OnExamination - Gastroenterology

An 81-year-old frail ضعيف man admitted with a stroke becomes increasingly drowsy after receiving nasogastric feeding for five days.

Which biochemical abnormality is the most likely cause of his drowsiness?

- 1- hyperglycaemia
- 2- hypermagnesaemia
- 3- hypernatraemia
- 4- hypocalcaemia
- 5- hypophosphataemia

Answer & Comments

Answer: 5- hypophosphataemia

The chronology of his presentation 5 days after receiving NG feeds suggests hypophosphataemia associated with the re-feeding syndrome. This is well described in elderly frail subjects who may have prior poor nutrition. However, other electrolyte abnormalities are also described in associated with NG feeds eg Hypermagnesaemia. But with this briefest of histories and the five days I suspect the examiner is looking for hypophosphataemia.

[Q: 777] OnExamination - Gastroenterology

A 75-year-old patient presents with watery diarrhoea. He is passing large volumes of watery diarrhoea, approximately 3litres a day, with no noticeable blood. It has been present for approximately 5 months and is gradually becoming more frequent. It often wakes him at night with the urge to defecate.

Liver function tests, calcium and urea and electrolytes are normal.

Stool microscopy and culture are normal, and clostridium difficile toxin is negative.

A flexible sigmoidoscopy is organised, and the investigator reports to you that the large bowel appears normal.

Which of the following treatments may this patient benefit from?

- 1- Gluten free diet
- 2- High fibre diet
- 3- Low residue diet
- 4- Oral cholestyramine
- 5- Oral prednisolone

Answer & Comments

Answer: 4- Oral cholestyramine

In the absence of infection and with this typical history in an elderly individual the diagnosis is likely to be microscopic colitis. This does not fulfil the ROME II criteria for IBS. Although Coeliac disease is a possibility, this is unlikely, given the patients age, and the presentation.

Microscopic colitis can only be diagnosed by colonoscopy and mucosal biopsy because, macroscopically, the colon appears normal. The incidence is increasing as the use of colonoscopy increases - almost certainly due to better diagnostic workup. Microscopic colitis is diagnosed in up to 10% of all patients undergoing colonoscopy for unexplained diarrhoea, an incidence which increases to

20% in those aged over 70 years. Microscopic colitis may be associated with bile acid malabsorption and may respond to either budesonide or cholestyramine.

[Q: 778] OnExamination -
Gastroenterology

With respect to liver cirrhosis which of the following statements is correct?

- 1- In end-stage cirrhosis, liver transplantation is associated with 20% 5 year survival
- 2- The final common pathway of hepatic fibrosis is mediated by the hepatic stellate cell
- 3- Tumour necrosis factor is an anti-inflammatory effector in fibrotic liver injury
- 4- Transforming growth factor is a potent promoter of the fibrogenic response by hepatocytes
- 5- Endothelin causes dilatation of the sinusoids, thus decreasing portal hypertension

Answer & Comments

Answer: 2- The final common pathway of hepatic fibrosis is mediated by the hepatic stellate cell

The hepatic stellate cells, which reside in the space of Disse are central to the process of fibrosis within the liver. Tumour necrosis factor- is a pro-inflammatory effector in fibrotic liver injury, through activation of the stellate cells, which then secrete the fibrillar collagen, constituting the defining features of hepatic fibrosis. Interleukin-10 is thought to exert anti-inflammatory effects on the stellate cell. Endothelin is a vasoconstrictor in the hepatic sinusoids (similarly in the endothelium of the systemic circulation), and functions by causing contraction of the hepatic stellate cells, thus increasing intrahepatic sinusoidal resistance, and promoting portal hypertension. Nitric Oxide antagonises the

effects of endothelin in the liver. 5 year survival after liver transplantation is now 75%. For an update on liver cirrhosis refer to BMJ 2003;327:143-7.

[Q: 779] OnExamination -
Gastroenterology

A 17-year-old girl is commenced on nasogastric feeding due to severe anorexia nervosa. Five days later she becomes increasingly confused.

On examination she was afebrile, appeared appropriately hydrated, with a pulse of 98 bpm and blood pressure 96/60 mmHg.

Which one of the following investigations should be requested forthwith?

- 1- Arterial blood gases
- 2- Phosphate
- 3- Serum Calcium
- 4- Serum Magnesium
- 5- Vitamin B concentrations

Answer & Comments

Answer: 2- Phosphate

The patient appears to have developed the refeeding syndrome. Refeeding malnourished patients increases basal metabolic rate, with glucose being the predominant energy source. This anabolic response causes intracellular movement of minerals, and serum levels may fall significantly. These rapid changes in metabolism and electrolyte movement may lead to severe cardiorespiratory and neurological problems resulting in cardiac and respiratory failure, oedema, lethargy, confusion, coma, convulsions, and death. The symptoms of the refeeding syndrome are thought to be due predominantly to hypophosphataemia, but metabolic changes in potassium, magnesium, glucose, and thiamine can also contribute. The probable answer here is therefore phosphate as hypophosphataemia seems probable.

Calcium depletion is possible but there is absence of tetany.

Zinc deficiency causes skin rashes periorally and around nostrils. Its extremely difficult to measure vitamin B concentrations plus her presentation does not sound like Wernicke's ?neurophthalmological features.

[Q: 780] OnExamination - Gastroenterology

A 32-year-old man develops profuse diarrhoea with mucus and blood. Biopsies from the flexible sigmoidoscopy shows evidence of ulcerative colitis.

Which of the following is true of the condition?

- 1- mesalazine therapy is associated with infertility in males
- 2- pseudopolyps on sigmoidoscopic examination have premalignant potential
- 3- topical 5-aminosalicylic acid are less effective than topical steroids in proctitis
- 4- colectomy may produce regression of gall bladder disease
- 5- goblet cells are unaffected in the mucosa

Answer & Comments

Answer: 4- colectomy may produce regression of gall bladder disease

Mesalazine is 5-aminosalicylic acid. Sulphasalazine is the combination of 5-ASA and sulphapyridine, the latter being a sulphonamide and causing oligospermia. Pseudopolyps are not premalignant and may occasionally regress. Topical 5-aminosalicylic acid are as effective as topical steroids in proctitis. Goblet cells are depleted in the mucosa.

[Q: 781] OnExamination - Gastroenterology

Which of the following statements regarding the genetic and immunological basis of Coeliac

Disease is correct?

- 1- 50% of patients are HLA-DQ 2 or HLA-DQ 8 positive.
- 2- alpha-gliadin specific CD8 cells can be identified in the intestinal wall of untreated patients with coeliac disease
- 3- Cow's milk proteins may precipitate an immune-related enteropathy indistinguishable from coeliac disease.
- 4- Tissue Transglutaminase generates the antigenic epitopes present in alpha-gliadin.
- 5- TNF- γ plays a critical role in the inflammatory response in the intestinal wall of patients with untreated celiac disease.

Answer & Comments

Answer: 4- Tissue Transglutaminase generates the antigenic epitopes present in alpha-gliadin.

The prevalence of Coeliac Disease is 1% in Western societies, and is thus one of the commonest immune-mediated diseases. It arises as a result of genetic predisposition, at least 95% of patients are HLA-DQ2 or HLA-DQ8 positive, and the specific immune response to the alpha-gliadin component of gluten. The action of tissue transglutaminase on alpha-gliadin generates epitopes to CD4+ T-lymphocytes, which provoke an inflammatory response in the intestinal wall. In untreated individuals, alpha-gliadin specific CD4+ T cells can be found producing interferon- γ in the intestinal wall. Cow's milk can produce an immunologically mediated enteropathy, but the condition is rare and transient.

[Q: 782] OnExamination - Gastroenterology

Which of the following statements concerning iron metabolism is correct?

- 1- Approximately 0.1% of body iron circulates in the plasma
- 2- Approximately 90% of dietary iron is absorbed in the intestine
- 3- The main route of excretion is the liver
- 4- The serum ferritin concentration is reduced characteristically following surgery
- 5- The transferrin content of intestinal mucosal cells is high when body iron stores are high

Answer & Comments

Answer: 1- Approximately 0.1% of body iron circulates in the plasma

Approximately 4mg of iron circulate within the plasma with a total body iron store of 3-4 g (2500 mg in the RBCs, 500mg in liver, 500 mg in macropahages and about 500 mg in muscle). From an intake of approx 6mg/1000kcal of dietary iron only 15% is bioavailable. The majority of iron contained within the RBCs is metabolised and re-utilised but 1mg per day is lost through the gut. Ferritin, the plasma protein responsible for binding iron is an acute phase reactant protein and increases in inflammatory conditions and following surgery. Transferrin is a glycoprotein responsible for internal ion exchange and the content within mucosal cells is naturally low in haemochromatosis with high saturation.

[Q: 783] OnExamination - Gastroenterology

A 46-year-old man with a family history of haemochromatosis presented to outpatients for advice.

Investigations revealed.

serum ferritin 453ug/L (15-300)

serum iron 29 umol/L (12-30)

serum iron binding capacity 46 umol/L(45-75)

iron saturation 63 per cent (20-50)

What is the most appropriate next step in management?

- 1- arrange for DNA analysis
- 2- begin a venesection programme
- 3- monitor his serum ferritin regularly
- 4- take no action unless the iron saturation exceeds 90 per cent
- 5- undertake a liver biopsy

Answer & Comments

Answer: 1- arrange for DNA analysis

This man is likely to have hereditary heamochromatosis (HHC). Homozygous mutation (C282Y mutation) of the Human Iron gene (HFE gene) accounts for over 80% of cases of HHC. The diagnosis is made on DNA analysis. If the diagnosis is confirmed then treatment with venesection to achieve and maintain a ferritin of 50-100?/l is indicated. A liver biopsy is not required to make the diagnosis of HHC although may be indicated for prognostic reasons if cirrhosis is suspected.

[Q: 784] OnExamination - Gastroenterology

Which of the following conditions may give a false/positive sweat test?

- 1- Conn syndrome
- 2- Hyperthyroidism
- 3- Hyperparathyroidism
- 4- Obesity
- 5- Glucose-6-phosphatase dehydrogenase deficiency

Answer & Comments

Answer: 5- Glucose-6-phosphatase dehydrogenase deficiency

Non-cystic fibrosis conditions associated with elevated concentrations of sweat electrolytes include:

" Endocrine: Untreated adrenal insufficiency, hereditary nephrogenic diabetes insipidus, hypothyroidism, hypoparathyroidism.

" Metabolic: Glucose-6-phosphate dehydrogenase deficiency, mucopolysaccharidoses, fucosidosis.

" Other: Ectodermal dysplasia, familial cholestasis, pancreatitis, malnutrition.

[Q: 785] OnExamination - Gastroenterology

A middle-aged woman presents with recent changes in bowel habit. She is investigated as a case of sporadic colonic carcinoma.

What is the mechanism of its tumorigenesis?

- 1- APC gene mutation
- 2- β -catenin suppression
- 3- Down-regulation of p27
- 4- K-ras suppression
- 5- p53 upregulation

Answer & Comments

Answer: 3- Down-regulation of p27

The cyclin-dependent kinase inhibitor p27 is a negative regulator of the cell cycle and a potential tumour suppressor gene. Its down-regulation is associated with occurrence of sporadic colon cancer. β -catenin accumulation, not suppression, initiates adenoma formation. p53 is a tumour suppressor gene. Activation of K-ras oncogene is seen in sporadic colon cancer.

[Q: 786] OnExamination - Gastroenterology

A 48-year-old man with malaise and abdominal pain is found to have a raised serum bilirubin of 60 μ M. The provocation test with intravenous nicotinic acid is positive.

What is the best course of action?

- 1- Corticosteroid
- 2- Sphincterotomy with endoscopic retrograde cholangiopancreatography (ERCP)
- 3- Cholestyramine
- 4- Reassure patient
- 5- Ursodeoxycholic acid

Answer & Comments

Answer: 4- Reassure patient

This patient has Gilbert's syndrome, which is a familial mild unconjugated hyperbilirubinaemia with an excellent prognosis. It is probably autosomal dominant. There are a number of abnormalities with bilirubin handling including hepatic uptake and conjugation. Investigations show a rise in unconjugated bilirubin on fasting, or by nicotinic acid. Reassure patient that condition is common and benign.

[Q: 787] OnExamination - Gastroenterology

With respect to gastric carcinoma, which of the following statements is true?

- 1- Incidence of distal stomach tumours is increasing
- 2- Aspirin use is a risk factor for gastric carcinoma
- 3- Helicobacter pylori infection is not associated with gastric carcinoma
- 4- Endoscopic ultrasonography is superior to conventional CT scanning for local tumour staging
- 5- Early diagnosis of gastric carcinoma results in a 5 year survival rate of 20%

Answer & Comments

Answer: 4- Endoscopic ultrasonography is superior to conventional CT scanning for local tumour staging

Incidence of distal stomach tumours is actually decreasing while the incidence of tumours in the proximal stomach is increasing. NSAID use is associated with decreased risk of certain gastric tumours. H. pylori infection has been associated in a number of studies with increased risk of gastric carcinoma. Screening for gastric carcinoma in Japan detects up to 40% of gastric carcinomas at an early stage, and, in skilled hands 5 year survival can be upwards of 90%. CT with gastric dilatation is an useful complementary investigation in the staging of gastric carcinoma, but endoscopic ultrasonography is superior to conventional CT scanning as it is able to assess depth of infiltration and lymphatic dissemination of tumour.

[Q: 788] OnExamination -
Gastroenterology

A 29-year-old male presents with symptoms of severe gastro-oesophageal reflux.

Which one of the following is most useful in assessing the role of surgery?

- 1- cardiac sphincter manometry
- 2- gastric emptying study
- 3- intragastric pH monitoring off therapy
- 4- oesophageal motility study
- 5- oesophageal pH monitoring on therapy

Answer & Comments

Answer: 4- oesophageal motility study

Laparoscopic fundoplication is the treatment of choice for patients with GORD refractory to or intolerant of, Proton Pump Inhibitor therapy. The patient should have had an endoscopy at least 6 months prior to surgery to exclude any unsuspected pathology ?Barrett's oesophagus or adenocarcinoma. An oesophageal transit study is indicated to rule out a primary motor disorder (eg achalasia, scleroderma) when suspected and to rule out aperistalsis, which may result in post-

operative dysphagia after some forms of fundoplication.

[Q: 789] OnExamination -
Gastroenterology

A 60-year-old man presents with a 5 day history of lower abdominal pain and diarrhoea. He has a history of chronic obstructive airways disease and has had numerous acute infective exacerbations over the last 3 months.

On examination he was dehydrated, with a temperature of 38.6 C, a blood pressure of 102/72 mmHg and has a distended, tender abdomen.

Which of the following is the most appropriate investigation for this patient?

- 1- Chest X-ray
- 2- Plain abdominal X-ray
- 3- Sigmoidoscopy and biopsy
- 4- Stool microscopy
- 5- Ultrasound scan of the abdomen

Answer & Comments

Answer: 2- Plain abdominal X-ray

This is pseudomembranous colitis due to Clostridium Difficile secondary to Antibiotic usage for his COAD. Plain AXR is useful for diagnosing toxic dilatation and would be the investigation of choice here due to his abdominal distension. So toxic dilatation should be excluded prior to sigmoidoscopy. However it does not establish the diagnosis. Stool microscopy has no value but stool toxin assay is useful. A Patient with diarrhoea normally has involvement of the distal colon and rectum and sigmoidoscopy with biopsy is helpful for rapid diagnosis but should not be performed if toxic dilatation is suspected. Patients with involvement of right colon usually have little or no diarrhoea.

[Q: 790] OnExamination -
Gastroenterology

49-year-old woman presents with a 6 month history of pruritus. Examination reveals jaundice, xanthelasma, scratch marks, vitiligo and 3cm hepatomegaly. She was afebrile. Liver function tests reveal raised bilirubin, alkaline phosphatase, gamma glutamyl transferase and mildly elevated alanine transaminase and aspartate transaminase.

Which of the following conditions will be most likely found in this woman?

- 1- Constipation
- 2- Haemolysis
- 3- Lymphadenopathy
- 4- Vitamin A deficiency
- 5- Vitamin B complex deficiency

Answer & Comments

Answer: 4- Vitamin A deficiency

The most likely diagnosis is primary biliary cirrhosis as evidenced by pruritus, hypercholesterolaemia, jaundice, raised ALP and γ -GT. Malabsorption of fat-soluble vitamins (A, D, K) is common.

[Q: 791] OnExamination -
Gastroenterology

A new diagnostic test for malabsorption has been analysed and the results have yielded the following 2x2 contingency table.

	Disease present	
	Yes	No
+ve test	0.9	0.1
-ve test	0.2	0.8

Applying this test to a case of chronic diarrhoea from a patient group where the prevalence of malabsorption is known to be 20% (probability = 0.2)

What is the probability of a patient having malabsorption if they have a positive test?

- 1- 0.16
- 2- 0.24
- 3- 0.48
- 4- 0.64
- 5- 0.8

Answer & Comments

Answer: 4- 0.64

This is tough but the College are putting more and more Evidence Based Medicine Questions into the exam. This question tests understanding of pre-test and post-test odds, likelihood ratios, sensitivity and specificity. The calculation is as follows.

$$\text{Sensitivity} = 0.9 / (0.9 + 0.2) = 0.818$$

$$\text{Specificity} = 0.8 / (0.1 + 0.8) = 0.889$$

$$\text{Likelihood ratio for a positive test (LR+)} = 0.818 / (1 - 0.889) = 7.2$$

$$\text{Pre-test odds} = 0.2 / (1 - 0.2) = 0.25$$

$$\text{Post-test odds} = \text{pre-test odds} \times \text{LR+} = 0.25 \times 7.2 = 1.8$$

$$\text{Post-test probability} = 1.8 / (1.8 + 1) = 0.64$$

		Disease present	
		Yes	No
test	result	true positive (A)	false positive (B)
test	result – ve	false negative (C)	true negative (D)

Sensitivity (how much a test is positive in disease) = $A / (A + C)$

Specificity (how much a test is negative in health) = $D / (B + D)$

$$\text{Positive Predictive Value} = A / (A + B)$$

$$\text{Negative Predictive value} = D / (C + D)$$

Pre-test odds = the odds of having the disease before you do the test (e.g. your rule-of-thumb guestimate or the prevalence of the disease in the population or based on clinical findings etc.)

Post-test odds = the odds of having the disease after you did the test

Systematic Error = $(A + B) / (A + C)$ = good statistic for - 1) breaking the ice at a party of epidemiologists, 2) confusing your fellow SpRs at meetings

Likelihood Ratio (LR) + (the ratio of the chance of having a +ve test if the disease is present to the chance of having a positive test if the disease is absent) = sensitivity / (1 - specificity)

LR- = $(1 - \text{sensitivity}) / \text{specificity}$

WHAT? ... Aghh! I knew I hated stats. Of what use is an LR?

Likelihood Ratios are good for

" directly calculating post-test odds

" tests with multiple levels (i.e. not just +ve or -ve). Calculate the LR at each level by taking the ratio of true +ves to false +ves both expressed as percentages of the total number tested.

" diseases requiring multiple tests. The post-test odds after one test is the pre-test odds for the next.

" bluffing your way in statistics, especially when talking to Evidence Based Medicine boffins

[Q: 792] OnExamination - Gastroenterology

Which of the following statements regarding lactose intolerance is correct?

- 1- Lactose is degraded to glucose and fructose by lactase
- 2- Lactose intolerance is commonest in white Northern Europeans
- 3- Lactose intolerance is best diagnosed with a methane breath test
- 4- Rotavirus infection may precipitate the diagnosis of lactose intolerance

- 5- Lactose intolerance is treated by glucose and galactose replacement therapy

Answer & Comments

Answer: 4- Rotavirus infection may precipitate the diagnosis of lactose intolerance

Lactase acts on lactose to generate glucose and galactose. Lactose intolerance is least common in white northern Europeans, and is more common in Asian, and East Asian races. Lactose intolerance may be diagnosed with a DNA assay of the Lactase gene, along with a Hydrogen breath test. Any GI infection may reveal lactose intolerance, as gut flora may be altered by large bowel bacterial or viral load, as well as the treatment of infection. A change from an Eastern to a Western, high lactose, diet, may also reveal lactose intolerance. Many patients labelled as having IBS may suffer from undiagnosed lactose intolerance, and many medications use lactose as a binding and stabilising agent. Treatment of lactose intolerance is with careful replacement of lactase.

[Q: 793] OnExamination - Gastroenterology

A 43-year-old male presents with weight loss and watery diarrhoea. Investigations reveal hypokalaemia with a pancreatic mass.

Which of the following would support the diagnosis of a VIPoma?

- 1- Achlorhydria
- 2- Hypoglycaemia
- 3- Increased Pancreatic polypeptide
- 4- Migratory erythema
- 5- Pellagra

Answer & Comments

Answer: 1- Achlorhydria

Achlorhydria is classically associated with VIPoma together with profuse diarrhoea, a

hypokalaemic acidosis and hyperglycaemia. Migratory erythema is associated with a glucagonoma. Although raised pancreatic polypeptide is seen with a VIPoma it is unusual and is more commonly associated with its own syndrome. Pellagra is associated with the carcinoid syndrome.

[Q: 794] OnExamination - Gastroenterology

A 36-year-old man presents with a 16 week history of indigestion. Five years previously he had been treated for a duodenal ulcer. Investigations reveal:

Fasting gastrin 120 pmol/L (<55)

Which one of the following statements regarding gastrin is correct?

- 1- It acts upon the G cells of the stomach
- 2- It inhibits the secretion of pancreatic bicarbonate
- 3- It is produced by the alpha cells of the pancreatic islets
- 4- It is produced by the parietal cells of the stomach
- 5- Its release is stimulated by gastric luminal peptides

Answer & Comments

Answer: 5- Its release is stimulated by gastric luminal peptides

Gastrin is mainly produced in 2 forms by the G cells of the gastric antrum. It stimulates the parietal cells to produce hydrochloric acid and its production is stimulated by neural reflex pathways and also by the direct effect of digested peptides on the G cells themselves. It also stimulates the production of bicarbonate.

[Q: 795] OnExamination - Gastroenterology

A 70-year-old woman presented with a history of pancreatitis and persistent diarrhoea. She

also gave a history of osteoporosis and had had a deep vein thrombosis.

Which one of the following drugs will become less effective after she starts taking Cholestyramine to relieve intolerable itching?

- 1- Aspirin
- 2- Folic Acid
- 3- Thiamine
- 4- Vitamin D
- 5- Warfarin

Answer & Comments

Answer: 4- Vitamin D

Cholestyramine is an anion exchange resin, and will interfere with the absorption of fat-soluble vitamins. Thus vitamin D absorption will be reduced, making treatment with this drug less effective when given along with cholestyramine. Cholestyramine may enhance or reduce the anticoagulant effect of warfarin (see BNF).

[Q: 796] OnExamination - Gastroenterology

A 40-year-old single man returned from holiday in Europe with mild bloody diarrhoea which had lasted for two weeks. He had lost 2.5 kg in weight, had occasional lower abdominal cramping discomfort and a painful swelling of his left knee.

What is the most likely diagnosis?

- 1- amoebiasis
- 2- campylobacter infection
- 3- Crohn's disease
- 4- gonococcal septicaemia
- 5- ulcerative colitis

Answer & Comments

Answer: 2- campylobacter infection

Campylobacter infection is one of the commonest causes of inflammatory diarrhoea. Abdominal pain is often a prominent feature of the illness, frequently localising to the right iliac fossa, Diarrhoea may be mild or very severe, often with passage of blood. Symptoms may last a week or longer. Reactive arthritis and Reiter's syndrome can develop following infection with a number of enteric pathogens, including Shigella, Salmonella, Campylobacter and Yersinia.

[Q: 797] OnExamination -
Gastroenterology

A 65-year-old woman presented with a malabsorption syndrome. She had a past history of radiotherapy for cervical cancer. Small intestine biopsy reveals - villous atrophy and crypt hypertrophy, chronic inflammatory cell infiltrate of the lamina propria together with increase in intra-epithelial lymphocytes.

What is the most likely diagnosis?

- 1- Bacterial overgrowth
- 2- Coeliac disease
- 3- Crohn's disease
- 4- Mesenteric ischaemia
- 5- Radiation enteropathy

Answer & Comments

Answer: 2- Coeliac disease

Don't be put off by the description of the case, these histological features are typical of Coeliac disease with villous atrophy, crypt hyperplasia/hypertrophy, inflammatory infiltrate of the lamina propria and intra-epithelial lymphocytes. Useful serology includes anti-TTG antibodies which would be expected in over 90% of cases. Treatment of this case would therefore entail gluten-free diet.

[Q: 798] OnExamination -
Gastroenterology

A 52 year-old male presents with general deterioration. He drinks approximately 25 units of alcohol each week and is a smoker of 5 cigarettes daily. Examination reveals that he is jaundiced, has numerous spider naevi on his chest and he has a temperature of 37.2°C. Abdominal examination reveals hepatosplenomegaly.

Investigations reveal:

Bilirubin 200 micromol/L (1-22)
Alkaline phosphatase 550 iu/l (45 - 105)
AST 258 iu/l (1 - 31)
Albumin 25 g/L (37 - 49)
hepatitis B virus surface antigen positive
hepatitis B virus e antigen negative
hepatitis B virus DNA undetectable

What is the most likely diagnosis?

- 1- Alcoholic liver disease
- 2- Autoimmune chronic active hepatitis
- 3- Carcinoma of the pancreas
- 4- Chronic hepatitis B infection
- 5- Chronic hepatitis D (delta) infection

Answer & Comments

Answer: 4- Chronic hepatitis B infection

HbsAg is positive, Hepatitis E antigen is negative and the DNA being undetectable suggests that it is Chronic HBV infection with low viral replication.

[Q: 799] OnExamination -
Gastroenterology

A 78 year-old female with hip osteoarthritis presents with altered bowel habit. She undergoes a sigmoidoscopy and rectal biopsy shows normal epithelium and pigment-laden macrophages in the lamina propria.

What is the most likely cause of these findings?

- 1- Diverticular disease
- 2- laxative abuse
- 3- mesenteric ischaemia
- 4- Non-steroidal anti-inflammatory drugs
- 5- Ulcerative colitis

Answer & Comments

Answer: 2- laxative abuse

She has 'melanosis coli' as a result of prolonged laxative use. Often the bowel mucosa looks dark and 'stained' during colonoscopy. She may be predisposed to constipation due to immobility from her arthritis and/or use of constipating pain killers.

[Q: 800] OnExamination - Gastroenterology

A 45-year-old female develops profuse watery diarrhoea with lower abdominal pain 7 days after undergoing laparoscopic cholecystectomy.

What is the most likely diagnosis?

- 1- Abdominal sepsis
- 2- Bile acid diarrhoea
- 3- Campylobacter gastroenteritis
- 4- Pseudomembranous colitis
- 5- Pseudo-obstruction

Answer & Comments

Answer: 4- Pseudomembranous colitis

Prophylactic antibiotics are frequently given in both laparoscopic and open cholecystectomy. Typically broad spectrum antibiotics are administered with a consequent risk of Pseudomembranous colitis. However, it must also be remembered that Clostridium difficile may also be contracted on the wards.

Bile acid diarrhoea may affect 10% of patients following cholecystectomy. Typically it is post-prandial; the bile, with no gall bladder to store it, is excreted directly into the gut.

[Q: 801] OnExamination - Gastroenterology

A 55-year-old male is admitted with vomiting. He has a long history of alcohol abuse, appears slightly jaundiced and is dishevelled and unkempt. He was started on an intravenous glucose infusion and Diazepam and he symptomatically improved.

One day later he becomes confused, developed vomiting, diplopia and was unable to stand.

What is the most likely diagnosis?

- 1- Benzodiazepine intoxication
- 2- Delirium tremens
- 3- Hepatic encephalopathy
- 4- Subdural haematoma
- 5- Vitamin B deficiency

Answer & Comments

Answer: 5- Vitamin B deficiency

This patient is manifesting signs of Wernicke's encephalopathy with confusion, oculomotor signs and ataxia affecting gait and stance. Wernicke's encephalopathy is a medical emergency, requiring urgent intravenous thiamine.

The episode has been precipitated by intravenous dextrose administration which has exhausted his vitamin B reserves, hence B vitamins must be administered to all alcoholic patients requiring dextrose.

[Q: 802] OnExamination - Gastroenterology

A 53-year-old woman with rheumatoid arthritis was referred with iron deficiency

anaemia. Endoscopy revealed several superficial antral erosions, with small bowel biopsy showing mild villous blunting, apoptotic bodies, occasional eosinophils and mild increase in chronic inflammatory cells. Colonoscopy was reported as normal.

What is the most likely cause of these findings?

- 1- coeliac disease
- 2- Crohn's disease
- 3- non-steroidal anti-inflammatory drug therapy
- 4- small bowel lymphoma
- 5- Whipple's disease

Answer & Comments

Answer: 3- non-steroidal anti-inflammatory drug therapy

This salient features in this patient's case revolve around the fact that she has rheumatoid arthritis (hence the requirement for NSAIDs), the iron deficiency anaemia and the superficial ulceration on endoscopy with features indicative of inflammation due to the chronic NSAID use. Coeliac disease is associated with villous atrophy and lymphocyte infiltration. There is no suggestion on the biopsy of lymphocyte infiltration which argues against lymphoma or celiac.

[Q: 803] OnExamination - Gastroenterology

A 35-year-old woman with a history of recurrent anaemia was noted to have target cells and Howell-Jolly bodies on a blood film examination.

Investigations revealed:

Haemoglobin	7.0 g/dL (11.3-16.5)
MCV	77 fl (80-96)
MCH	26.2 pg (28-32)
Serum B12	140 ug/L (160-760)

Red cell folate 95 ug/L (160-640)

Serum ferritin 10 ug/L (15-300)

What disease specific antibody is most likely to be present?

- 1- Anti-endomysial
- 2- Anti-gastric parietal cell
- 3- Anti-glutamic acid decarboxylase
- 4- Anti-intrinsic factor
- 5- Antimitochondrial

Answer & Comments

Answer: 1- Anti-endomysial

The patient has hyposplenism as suggested by the blood film and a mixed anaemia. Coeliac disease could therefore fit the above picture with anti-endomysial antibodies being the most appropriate selection from the above list. Antimitochondrial antibodies are seen in PBC, anti-gastric and anti intrinsic Abs are seen in pernicious anaemia. Anti-GAD abs are found in auto-immune DM.

Screening for coeliac disease should include high-risk groups such as anaemia (iron or folate deficiency), hyposplenism, reduced bone density and infertility.

"Anti-endomysial IgA antibodies are extremely specific markers for CD and for dermatitis herpetiformis. These antibodies are directed to a component of the gut endomysium (connective tissue surrounding smooth muscle fibers of the gut).

[Q: 804] OnExamination - Gastroenterology

A 22-year-old man presented to casualty one week after returning from a six month visit to Pakistan. He complained of fever, rigors and headache. On examination he was febrile (38 C) with a blood pressure of 115/65 mmHg, and a pulse of 100/minute.

His abdomen was tender in the right upper quadrant.

Investigations showed:

Hb 11.0 g/dL

WBC $15.5 \times 10^9/L$

Neutrophils $13.5 \times 10^9/L$

Platelets $350 \times 10^9/L$

Blood film No malaria parasites seen

Alk Phos 450 iU/L

AST 50 iU/L

CRP 88 mg/L

Stool culture Negative

Chest x-ray: Small right pleural effusion noted

Which of the following investigations would be of most diagnostic value?

- 1- Hepatitis E serology
- 2- Sigmoidoscopy
- 3- Stool microscopy for ova, cysts and parasites
- 4- Typhoid serology
- 5- Ultrasound scan of the abdomen

Answer & Comments

Answer: 5- Ultrasound scan of the abdomen

The presentation is not consistent with Hepatitis E infection. Typhoid serology is unreliable. The differential diagnosis is mainly pyogenic or amoebic liver abscess. Pyogenic abscesses present with swinging pyrexia, neutrophilia and high inflammatory markers. Right-sided pleural effusions are common and blood cultures are often positive. The presentation of amoebic liver abscess (ALA) is very similar. Most patients do not have bowel symptoms at any time and amoebic cysts are found in stool in less than 50% of proven cases of ALA. Serology is the main stay of diagnosis. Ultrasound scan would confirm most moderate-sized to large liver abscesses; and

could guide a diagnostic aspiration, Small lesions are best demonstrated by CT or MRI.

[Q: 805] OnExamination - Gastroenterology

A group of construction workers presented to the accident and emergency department with diarrhoea, flushing, sweating and a hot mouth. They fell ill minutes after eating lunch in the staff canteen. They admitted that they had eaten tuna fish and wine.

What is the likely cause of food poisoning?

- 1- Clostridium perfringens
- 2- Heavy metal
- 3- Mushroom
- 4- Scrombotoxin
- 5- Staphylococcus aureus

Answer & Comments

Answer: 4- Scrombotoxin

Scrombotoxin food poisoning is caused by the ingestion of foods that contain high levels of histamine and possibly other vasoactive amines and compounds. Histamine and other amines are formed by the growth of certain bacteria and the subsequent action of their decarboxylase enzymes on histidine and other amino acids in food, either during the production of a product such as Swiss cheese or by spoilage of foods such as fishery products, particularly tuna or mahi mahi. Incubation period is 10-60 minutes.

[Q: 806] OnExamination - Gastroenterology

A previously well 40-year-old man is admitted with a single haematemesis after taking 300 mg of aspirin five hours previously.

On examination, pulse was 120/min with a blood pressure of 110/75 mmHg (lying) and 90/60 mmHg (standing). Respiratory and

abdominal examination was otherwise normal.

His haemoglobin concentration returned as 7 g/dL (13.0 - 16.5).

What is the most likely cause of his haemetemesis?

- 1- Angiodysplasia
- 2- Duodenal ulcer
- 3- Gastric cancer
- 4- Gastric erosions
- 5- Oesophagitis

Answer & Comments

Answer: 4- Gastric erosions

The most likely answer is gastric erosions based upon the fact that the incident has occurred after only one dose of Aspirin without any prior history of chronic usage which is associated with oesophagitis and ulcer formation. Malignancy is unlikely because of history of being fit and also the age.

[Q: 807] OnExamination - Gastroenterology

A 52-year-old man with a diagnosis as a child of coeliac disease had been asymptomatic despite poor dietary compliance. He presents with a one month history of intermittent, colicky, central abdominal pain and 3 kilogram weight loss and positive faecal occult bloods.

What is the most appropriate investigation?

- 1- Anti-endomysial antibody.
- 2- Colonoscopy.
- 3- CT scan of abdomen.
- 4- Distal duodenal biopsy.
- 5- Small bowel enema.

Answer & Comments

Answer: 2- Colonoscopy.

New-onset weight loss, with positive faecal occult bloods and central abdo pain in a 52-year-old man must be assumed to be colonic carcinoma until proven otherwise. Colonoscopy is the best way to check for this and would also demonstrate inflammatory bowel disease if present. If the colonoscopy were negative, then an OGD would be needed to check for upper GI malignancy.

[Q: 808] OnExamination - Gastroenterology

A 70 year-old man is admitted with pruritus, jaundice and a 2kg weight loss of two weeks duration. He had not drunk any alcohol for at least eight years. One month ago, he had completed a course of Co-Amoxiclav which had been prescribed by his GP for sinusitis and was also taking Ibuprofen for hip osteoarthritis. Investigations reveal:

Albumin 38 g/L (37-49)

Bilirubin 200 umol/L (1-22)

AST 200 iu/L (5-35)

Alkaline Phosphatase 200 iu/l (50-110)

Abdominal ultrasound reveals gallstones but no biliary duct dilatation

What is the most likely cause of his jaundice?

- 1- Cholangio-carcinoma
- 2- Co-Amoxiclav
- 3- Hepatitis B infection
- 4- Hepatitis C infection
- 5- Ibuprofen

Answer & Comments

Answer: 2- Co-Amoxiclav

Co amoxiclav (Augmentin) is notorious for causing drug-induced jaundice, often with a mixed hepatic/cholestatic picture. A 4 week delay in symptoms and signs is not unusual. Flucloxacillin is another common culprit. The

patient must be warned that this could re-occur if he is given Co amoxiclav again.

[Q: 809] OnExamination - Gastroenterology

Which statement is true concerning iron?

- 1- Iron absorption is mainly in the distal jejunum.
- 2- Parenteral iron is indicated if the haemoglobin level is not raised within 3 days by oral iron.
- 3- Sustained release preparations are useful if larger doses are required.
- 4- 200mg iron sulphate has more elemental iron than an equal dose of iron gluconate.
- 5- Absorption is prevented by ascorbic acid.

Answer & Comments

Answer: 4- 200mg iron sulphate has more elemental iron than an equal dose of iron gluconate.

Important for the structure of haemoglobin and myoglobin for O₂ and CO₂ transport; oxidative enzymes; cytochrome C and catalase. Absorbed in ferrous form in small bowel according to body need, aided by gastric juice and ascorbic acid; hindered by fibre, phytic acid and steatorrhoea. Transported in plasma in ferric state bound to transferrin; stored in liver, spleen, bone marrow and kidney as ferritin and haemosiderin; conserved and reused; minimal losses in urine and sweat; about 90% of intake excreted in stool. Ferrous sulphate contains about twice the amount of elemental iron as the gluconate. Levels raise Hb levels about 0.5g/100ml per week. Sustained release preparations should not be used, as they delay release beyond the early small bowel, where most iron absorption occurs.

[Q: 810] OnExamination - Gastroenterology

A 32 year-old woman with Crohn's Disease has a history of a right hemicolectomy for ileo-colonic disease. Since the operation she has had frequent diarrhoea but no blood in the stools.

Investigations show:

ESR 10

PLT 240

serum CRP 7 (< 10)

Which is the best treatment?

- 1- Cholestyramine
- 2- Mesalazine
- 3- Metronidazole
- 4- Omeprazole
- 5- Prednisolone

Answer & Comments

Answer: 1- Cholestyramine

The ESR, CRP and platelet counts are not raised, indicating that this patient's symptoms are not due to active Crohn's.

Also the diarrhoea is not bloody which goes against active Crohn's colitis. Hence mesalazine or prednisolone would not be effective here. Metronidazole is typically given for peri-anal disease. The history includes a previous right hemicolectomy for ileo-colonic disease. Loss of the terminal ileum frequently leads to bile salt malabsorption and treatment with the bile salt chelator cholestyramine quickly relieves the problem.

[Q: 811] OnExamination - Gastroenterology

Reflux oesophagitis of gastric contents

- 1- is a cause of asthma
- 2- can be improved by Helicobacter pylori eradication

- 3- Occurs during transient relaxation of the lower oesophageal sphincter
- 4- Is neutralised by bicarbonate secreted by the oesophageal mucosa
- 5- Can be excluded by a normal appearance at endoscopy

Answer & Comments

Answer: 3- Occurs during transient relaxation of the lower oesophageal sphincter

Diagnosis is based predominantly on history, with a very proportion of patients with reflux disease having a normal endoscopy. H pylori eradication is indicated in long term healing of gastric and duodenal ulceration, but not reflux disease. Brunner's glands are found in the duodenum which secrete alkaline mucus. Intra-oesophageal PH monitoring is used to exclude reflux as cause of bronchoconstriction. Reflux oesophagitis of gastric contents is a cause of chronic cough and not asthma.

[Q: 812] OnExamination - Gastroenterology

A 24-year-old woman has ingested an unknown quantity of Paracetamol tablets 4 hours ago. She now presents with nausea, vomiting, anorexia and right subchondral pain.

Which of the following features suggest that she should be transferred to the liver unit?

- 1- ALT 800 units/L
- 2- Blood glucose 5 mmol/L
- 3- Heart rate 120 BPM
- 4- pH 7.25
- 5- Systolic BP 100 mmHg

Answer & Comments

Answer: 4- pH 7.25

A pH of less than 7.3 is a poor prognostic factor for this patient.

The criteria for transfer to a specialist unit are:

Encephalopathy

INR >2.0 at <48h or >3.5 at <72h

Serum creatinine >200 µmol/L

Blood pH <7.3

Systolic BP <80 mmHg

[Q: 813] OnExamination - Gastroenterology

A 40 year-old man is referred with gastro-oesophageal reflux disease (GORD).

Which of the following concerning GORD is correct?

- 1- Acid suppressant therapy should not be given continuously
- 2- Endoscopy is mandatory
- 3- In the presence of Barrett's oesophagus, the risk of future malignancy can be assessed endoscopically without biopsy
- 4- Oesophageal pH monitoring is a good guide to therapy
- 5- Symptoms do not correlate with mucosal status at endoscopy

Answer & Comments

Answer: 5- Symptoms do not correlate with mucosal status at endoscopy

Symptoms of GORD do not correlate with the mucosal appearances at endoscopy. Although endoscopy should be performed in cases that are not clear cut or do not respond to PPI, it is not mandatory. The risk with Barrett's and hence the diagnosis of Barrett's can only be clarified with biopsy.

Monitoring of pH is not a good guide to therapy but symptomatic improvement is a good guide to the efficacy of therapy. PPIs can be given continuously where the diagnosis has been satisfactorily proven and relapse of symptoms persist after withdrawal.

[Q: 814] OnExamination -
Gastroenterology

Which ONE of the following statements is true of autoimmune hepatitis:

- 1- It usually presents as an acute hepatitis
- 2- It rarely presents before 20 years of age
- 3- It may be associated with keratoconjunctivitis sicca
- 4- It is associated with hypogammaglobulinaemia
- 5- It rarely interferes with menstruation except in later stages

Answer & Comments

Answer: 3- It may be associated with keratoconjunctivitis sicca

It occurs frequently in young (10-20 years) and middle-aged women. 25% present as acute hepatitis, but usually the onset is insidious. Some may be asymptomatic for years and then are found to have signs of chronic liver disease. Amenorrhoea is common. It is associated with hyperglobulinaemia and other autoimmune disease. 60% are associated with HLA-B8, DR3 and Dw3. The sicca syndrome (xerostomia/dry eyes, keratoconjunctivitis sicca) may occur.

[Q: 815] OnExamination -
Gastroenterology

Which of the following is most commonly associated with the development of pseudo-membranous colitis?

- 1- Cefuroxime
- 2- Ciprofloxacin
- 3- Co-trimoxazole
- 4- Erythromycin
- 5- Flucloxacillin

Answer & Comments

Answer: 1- Cefuroxime

Clostridium difficile a gram positive anaerobic bacterium is the cause of pseudo-membranous colitis. Studies show that when *C. difficile* colonize the gut, they release two potent toxins, toxin A and toxin B, which bind to certain receptors in the lining of the colon and ultimately cause diarrhea and inflammation of the large intestine, or colon (colitis). Commonly the disease is caused by broad spectrum antibiotics most commonly - cephalosporins, broad spectrum penicillins and clindamycin. Less commonly, macrolides and quinolones have been reported to cause the disorder. Appropriate treatment includes metronidazole and oral vancomycin.

[Q: 816] OnExamination -
Gastroenterology

Which one of the following organs is in direct contact with the anterior surface of the left kidney, without being separated from it by peritoneum?

- 1- Duodenum
- 2- Jejunum
- 3- Pancreas
- 4- Spleen
- 5- Stomach

Answer & Comments

Answer: 3- Pancreas

This is a basic anatomy question. However the only retroperitoneal structure is the pancreas, the body of which is in direct approximation to the anterior surface of the left kidney

[Q: 817] OnExamination -
Gastroenterology

A 42-year-old female with Ulcerative Colitis is found to have anti-smooth muscle antibodies.

Which is the next most appropriate test for this patient?

- 1- Abdominal Ultrasound
- 2- Colonoscopy
- 3- Full blood count
- 4- Liver biopsy
- 5- Liver function tests

Answer & Comments

Answer: 5- Liver function tests

The most appropriate investigation for this woman is LFTs to begin with to assess if there are any features of autoimmune hepatitis i.e. raised bilirubin, AST, ALT and Alkaline Phosphatase. If this is the case then liver biopsy may be required or further diagnostic imaging.

[Q: 818] OnExamination - Gastroenterology

A 67-year-old man with known aortic valvular disease is admitted with deteriorating dyspnoea. Investigations show:

haemoglobin 9 g/dL (12-16) MCV 70 fL (80-96)

upper gastrointestinal tract endoscopy: normal

duodenal biopsy: normal

Which one of the following investigations is most likely to provide the diagnosis?

- 1- Barium enema
- 2- colonoscopy
- 3- CT abdomen
- 4- mesenteric angiography
- 5- small bowel enema

Answer & Comments

Answer: 2- colonoscopy

In the older age group investigation of the lower GI tract is vital to exclude a lower GI malignancy. CT scans do not demonstrate colonic pathology as well as colonoscopy which is still considered the gold standard. Angiography is only helpful if the patient is bleeding briskly at the time of the examination.

[Q: 819] OnExamination - Gastroenterology

A 24-year-old woman had ulcerative colitis for seven years and was prescribed mesalazine 1.5 g per day. She smoked 20 cigarettes per day and was 10 weeks pregnant. She complained of worsening symptoms with six bloody stools per day.

Which one of the following statements is correct?

- 1- Azathioprine is contraindicated.
- 2- Initiation of an elemental diet risks fetal malnutrition.
- 3- Oral corticosteroids are contraindicated.
- 4- Oral mesalazine therapy should be withdrawn.
- 5- Termination of the pregnancy is advisable.

Answer & Comments

Answer: 1- Azathioprine is contraindicated.

The effect of pregnancy on UC is variable. Oral corticosteroids and mesalazine are not contraindicated. In general, the health of a mother with UC is the best predictor of the outcome of the pregnancy. Hence drug treatment is preferred to leaving active disease untreated. The BNF states that azathioprine should not generally be started during pregnancy, but it is only relatively contraindicated. However, azathioprine is concentrated in breastfeeding. In the context of pregnancy, an elemental diet does not risk maternal and/or fetal malnutrition.

[Q: 820] OnExamination -
Gastroenterology

A 28-year-old lady develops abdominal pain, jaundice and ascites worsening over a week. She drinks ten units of alcohol each week and takes the oral contraceptive pill.

Which of the following findings would make a diagnosis of hepatic vein thrombosis (Budd-Chiari syndrome) MOST likely?

- 1- alanine aminotransferase of 345 U/L (5 - 35)
- 2- acute liver failure
- 3- ankle oedema
- 4- ascites fluid protein of 38 g/L
- 5- tender enlarged liver

Answer & Comments

Answer: 5- tender enlarged liver

The most common causes of an acute severe liver injury in a young woman are: viruses (including: HAV, HBV), drugs (particularly paracetamol OD), Autoimmune hepatitis, and hepatic vein thrombosis (often precipitated by pregnancy or OCP use). The presence of liver failure, ankle oedema, and an exudative ascites do not help differentiate between these aetiologies. The ALT of 345 is moderately elevated and compatible with BCS. With viral or drug related hepatitis the peak ALT is usually much higher than this, the ALT may already be on the way down if she has had symptoms for a week. Tender hepatomegaly is one of the hallmarks of BCS. In acute severe viral, autoimmune or drug / toxin related liver disease the necrotic liver decreases in size.

[Q: 821] OnExamination -
Gastroenterology

A 30 year-old male presents with acute, profuse, watery diarrhoea with some blood after returning from a holiday in Tanzania. He had been taking oral rehydration salts.

Which one of the following is the most appropriate treatment?

- 1- Ciprofloxacin
- 2- Loperamide
- 3- Metronidazole
- 4- Prednisolone
- 5- Vancomycin

Answer & Comments

Answer: 1- Ciprofloxacin

The most likely cause of such travellers diarrhoea is *Escherichia coli* and hence ciprofloxacin is recommended for first line antibiotic therapy (when needed) before stool culture results are available. Metronidazole would be suitable for *Giardia* infection but its course is usually more insidious.

[Q: 822] OnExamination -
Gastroenterology

A 17-year-old student returns from a back-packing trip to Nepal with a two-week history of offensive diarrhoea and weight loss.

What is the most likely infective organism?

- 1- *Escherichia coli* 0157
- 2- *Giardia intestinalis* (G.lamblia)
- 3- *Shigella flexneri*
- 4- *Salmonella typhi*
- 5- *Yersinia enterocolitica*

Answer & Comments

Answer: 2- *Giardia intestinalis* (G.lamblia)

The best bet here is Giardiasis as it presents as chronic diarrhoeal illness due to duodenal infestation by the faeco-oral route. Malabsorption can occur along with epigastric discomfort and flatulence. *Escherichia coli* does not have a chronic illness (neither does *Shigella*) and like *Yersinia* causes bloody diarrhoea. *Salmonella typhi* is likely to cause a

particularly serious systemic illness in this patient.

[Q: 823] OnExamination -
Gastroenterology

Which of the following concerning the conjugation of bilirubin is correct?

- 1- is catalysed by a glucuronyl transferase
- 2- occurs in the Kupfer cells of the liver
- 3- is increased by valproate
- 4- is inhibited by rifampicin
- 5- is impaired in Dubin-Johnson syndrome

Answer & Comments

Answer: 1- is catalysed by a glucuronyl transferase

b - Hepatocytes.

c - Enzyme inhibitor.

d - Enzyme inducer.

e - Conjugation is OK but excretion from the hepatocyte into the bile is impaired. (Gilbert's syndrome - bilirubin can't go in to the hepatocyte - unconjugated bilirubinaemia. Crigler-Najjar syndrome - bilirubin can't conjugate - unconjugated bilirubinaemia. Dubin-Johnson syndrome - bilirubin can't depart from the hepatocyte - conjugated bilirubinaemia.)

[Q: 824] OnExamination -
Gastroenterology

A 51-year-old man was brought to Accident and Emergency for loose stools. He was dehydrated, weak and in shock. He had previously been complaining of large stool volumes for a 1 month period. Stool colour was normal. There was no history of laxative abuse and no significant past medical history.

What is the most likely diagnosis?

- 1- Carcinoid syndrome

- 2- Diabetic diarrhoea
- 3- Gastrinoma
- 4- Systemic mastocytosis
- 5- VIPoma

Answer & Comments

Answer: 5- VIPoma

VIPomas are endocrine tumours that secrete excessive amounts of VIP32, which causes a distinct syndrome characterized by large-volume watery diarrhoea, hypokalaemia, and dehydration. This syndrome is also called Verner-Morrison syndrome, pancreatic cholera, or WDHA syndrome for watery diarrhoea, hypokalaemia, and achlorhydria, which some patients develop. The mean age of patients is 49 years; however, it can occur in children, and when it does is usually caused by a ganglioneuroma or ganglioneuroblastoma. A stool volume of <700 mL/d excludes the diagnosis of VIPoma.

[Q: 825] OnExamination -
Gastroenterology

A 68-year-old male presents with alcoholic cirrhosis complicated by mild ascites.

Which of the following features is likely in this patient?

- 1- Increased serum sodium
- 2- Increased vascular resistance
- 3- Reduced urinary potassium excretion
- 4- Reduced renin concentrations
- 5- Reduced urinary sodium excretion

Answer & Comments

Answer: 5- Reduced urinary sodium excretion

Remember they have secondary hyperaldosteronism - sodium retention with consequent potassium loss. There is decreased vascular resistance, increased plasma volume and low serum sodium.

[Q: 826] OnExamination -
Gastroenterology

A 26-year-old presents in the first trimester of her first pregnancy (six weeks gestation) for an ante-natal check, she feels well. Blood tests show a Bilirubin of 40 $\mu\text{mol/l}$ the other LFT's are completely normal.

The most likely diagnosis is:

- 1- Gilbert's syndrome
- 2- Primary biliary cirrhosis
- 3- Primary sclerosing cholangitis
- 4- Dubin-Johnson syndrome
- 5- Cholestasis of pregnancy

Answer & Comments

Answer: 1- Gilbert's syndrome

Gilbert's is the most common condition causing mild isolated hyperbilirubinaemia. PBC & PSC are much less common conditions and are almost always associated with a rise in the other LFT's (particularly ALP & GGT). DJS is much less common than Gilbert's. Intrahepatic cholestasis of pregnancy is relatively common but usually occurs in the second or third trimester, ALP is usually high, risk increases with multiparity.

[Q: 827] OnExamination -
Gastroenterology

A 52-year-old woman presented with history of worsening dysphagia over many years. Recently there had been episodes of ill-defined central chest discomfort and nocturnal cough.

What is the most likely diagnosis?

- 1- achalasia
- 2- Barrett's oesophagus
- 3- motor neurone disease
- 4- oesophageal carcinoma
- 5- pharyngeal pouch

Answer & Comments

Answer: 1- achalasia

Achalasia presents most often in the 3rd - 5th decade. Symptoms usually develop years before the patient presents. Vague chest discomfort is common. 30% have a nocturnal cough due to aspiration of oesophageal contents.

Barrett's oesophagus does not cause dysphagia.

MND causes dysphagia due to problems with chewing and initiating a swallow and would not cause chest discomfort.

Oesophageal carcinoma is very unlikely due to the duration of symptoms (years).

A pharyngeal pouch usually presents in the 6th-7th decade with regurgitation and would not cause chest discomfort

[Q: 828] OnExamination -
Gastroenterology

A 50-year-old woman with a long history of alcohol abuse is prescribed Phenytoin for epilepsy. Examination was normal except for a liver edge. Her full blood count reveals

haemoglobin 10.0 g/dL (13-18)

MCV 122 fL (80-96)

white cell count $2.2 \times 10^9/\text{L}$ (4-11)

platelet count $85 \times 10^9/\text{L}$ (150-400)

What is the most likely explanation for these results?

- 1- Alcoholic liver disease
- 2- Aplastic anaemia
- 3- Folic acid deficiency
- 4- Hypothyroidism
- 5- Vitamin C deficiency

Answer & Comments

Answer: 3- Folic acid deficiency

Folic acid deficiency would give all these results. In addition she has good reason to be folate deficient- drinks a considerable amount and is on anticonvulsants.

Alcoholic liver disease, on its own would not make you leucopenic.

Hypothyroidism, would cause a raised MCV, but not the other parameters.

Scurvy does not cause this picture.

Aplastic anaemia could cause this haematological picture, but the clinical scenario leads you towards folic acid deficiency.

[Q: 829] OnExamination - Gastroenterology

A 42-year-old female presents with tiredness. Her investigations reveal:

Haemoglobin 7.8 g/dl (11.5 - 16.5)

MCV 72 fL (80 - 96)

white cell count $7.6 \times 10^9/L$ (4 - 11)

platelet count $350 \times 10^9/L$ (150 - 400)

serum ferritin 8 µg/L (15 - 300)

She was commenced on oral iron therapy and one month later her haemoglobin concentration was 8.0 g/dl.

What is the most likely cause of the failure of her haemoglobin to respond to this treatment?

- 1- coeliac disease
- 2- folate deficiency
- 3- inadequate dosage of iron
- 4- poor compliance with therapy
- 5- sideroblastic anaemia

Answer & Comments

Answer: 4- poor compliance with therapy

The most likely explanation for the failure of an iron deficiency anaemia to respond to iron

therapy in a menstruant female is poor compliance. It is likely that the dose that this patient is prescribed would be adequate and if not some response would still be expected. There is no evidence of a concomitant folate deficiency as suggested by the blood picture, which would also argue against Coeliac disease. Similarly, there is no evidence to suggest a sideroblastic anaemia where a raised MCV and increased ferritin may be expected.

[Q: 830] OnExamination - Gastroenterology

Which of the following is activated by Cholera toxin?

- 1- Adenylate cyclase
- 2- Guanylate cyclase
- 3- Peroxisome proliferator receptor (PPAR) gamma
- 4- Sodium/potassium ATPase
- 5- The glucose-sodium transporter

Answer & Comments

Answer: 1- Adenylate cyclase

Cholera toxin activates adenylate cyclase with generation of cAMP.

[Q: 831] OnExamination - Gastroenterology

A 55 year-old woman presents with lethargy, diarrhoea together with joint pains and intermittent fever. These symptoms have developed over the six months during which time she has lost 6 kg in weight.

Supraclavicular lymphadenopathy is noted.

What is the most likely diagnosis?

- 1- bacillary dysentery
- 2- campylobacter infection
- 3- Coeliac disease
- 4- giardiasis

5- Whipple's disease

Answer & Comments

Answer: 5- Whipple's disease

Whipple's disease is caused by Tropheryma Whippeli and symptoms include chronic diarrhoea, arthralgia, pyrexia and lymphadenopathy. Diagnosis is by microscopy of Jejunal biopsy specimen which shows macrophages with PAS positive granules.

Treatment is Cotimoxazole.

Bacillary dysentery and c.jejuni infection is characterised by bloody diarrhoea and is not chronic.

Coeliac disease and Giardiasis has no lymph involvement.

[Q: 832] OnExamination - Gastroenterology

A 24-year-old man with chronic diarrhoea and malabsorption is suspected of having coeliac disease. A jejunal biopsy is taken.

Which of the following findings would be expected in coeliac disease?

- 1- Shows leaf-shaped villi
- 2- Shows flattening of the crypts
- 3- Appearances may resemble severe tropical sprue
- 4- Shows fissures penetrating into the submucosa
- 5- Characteristically shows epithelial cells distended with fat globules

Answer & Comments

Answer: 3- Appearances may resemble severe tropical sprue

In coeliac disease, the villi are shortened and the crypts lengthened with increased lymphocytic infiltrate. Tropical sprue may also

cause subtotal villous atrophy. Fissures are not found and epithelial cells are normal.

[Q: 833] OnExamination - Gastroenterology

A 65 year-old male presents with a four month history of diarrhoea with pale stools and weight loss.

Relevant results show:

Calcium 1.8 mmol/L (2.2-2.6)

Alkaline phosphatase 350 U/L (45-105)

What is the most likely diagnosis?

- 1- coeliac disease
- 2- Giardia lamblia infection
- 3- pancreatic carcinoma
- 4- Small Intestinal bacterial overgrowth
- 5- Whipple's disease

Answer & Comments

Answer: 3- pancreatic carcinoma

The patient has a marked osteomalacia associated with malabsorption. In this age pancreatic carcinoma is the most probable diagnosis. Coeliac disease very seldom causes such an increased alk phos and is more likely to present with iron deficiency anaemia. The villous atrophy caused by Giardia is very transient. Whipples is extremely rare, found in middle aged men and caused by a bacillus, Tropheryma Whippelii.

[Q: 834] OnExamination - Gastroenterology

A 50-year-old male with a history of alcohol excess, presents with a 2 week history of confusion.

Which of the following strongly suggests a diagnosis of Korsakoff's psychosis?

- 1- delusional jealous beliefs
- 2- epileptic seizures

- 3- impaired long term memory
- 4- inventing recent events
- 5- visual hallucinations

Answer & Comments

Answer: 4- inventing recent events

Korsakoff's is associated with short term memory loss, with subsequent compensatory confabulation by the patient. Other symptoms may include delirium, anxiety, fear, depression, confusion, delusions and insomnia; painful extremities, sometimes bilateral wrist drop, but more frequently bilateral foot drop with pain or pressure over the long nerves. The treatment is intravenous thiamine, and attention to the consequences of alcohol withdrawal.

[Q: 835] OnExamination - Gastroenterology

A 20-year-old woman was referred for investigation of iron deficiency anaemia. Her mother died aged 28 years from colonic carcinoma complicating Peutz-Jeghers syndrome.

Which is the most likely mode of inheritance of Peutz-Jeghers syndrome?

- 1- Autosomal dominant
- 2- Autosomal recessive
- 3- Mitochondrial
- 4- Polygenic
- 5- X-linked dominant

Answer & Comments

Answer: 1- Autosomal dominant

Peutz Jegher syndrome is a condition characterised by perioral pigmentation and numerous hamartomas of the bowel. Originally it was assumed that these did not predispose to malignancy but studies now

suggest the contrary. The condition is autosomal dominant.

[Q: 836] OnExamination - Gastroenterology

Which one of the following require urgent referral for upper endoscopy?

- 1- A 45-year-old male with a one month history of persistent dyspepsia.
- 2- A 56-year-old male with a one month history of dyspepsia and a pulsatile central abdominal mass
- 3- A 73-year-old male with a three month history of dyspepsia which has failed to respond to a course of proton pump inhibitors
- 4- A 35-year-old male who has a history of waterbrash and dyspepsia which has responded to a course of ranitidine but since stopping has recurred.
- 5- A 62-year-old male with a three month history of unexplained weight loss, tenesmus and a right abdominal mass.

Answer & Comments

Answer: 3- A 73-year-old male with a three month history of dyspepsia which has failed to respond to a course of proton pump inhibitors

Criteria for referral for urgent endoscopy include dysphagia (at any age); dyspepsia at any age combined with any one of weight loss, anaemia or vomiting; dyspepsia in a patient aged 55 or above with onset of dyspepsia within one year and persistent symptoms; Dyspepsia with one of Barrett's oesophagus, FH of upper GI carcinoma, pernicious anaemia or Upper GI surgery more than 20 years ago; Jaundice; abdominal mass. With regard to the presented cases, the second case has dyspepsia with what seems to be an aortic aneurysm. This requires a ultrasound and vascular opinion. In the last case of unexplained weight loss, tenesmus and upper

right mass the problem is likely to be a colonic carcinoma.

[Q: 837] OnExamination -
Gastroenterology

A 28-year-old male presents with a four day history of profuse bloody diarrhoea after returning from a holiday in the Far East.

Which of the following regarding his illness is true?

- 1- a negative amoebic fluorescent antibody test excludes a diagnosis of acute amoebic dysentery
- 2- Cysts to Entamoeba histolytica in the stools confirms a diagnosis of acute amoebic dysentery
- 3- cholera is a likely diagnosis
- 4- Giardiasis is a likely diagnosis
- 5- shigellosis is a likely diagnosis

Answer & Comments

Answer: 5- shigellosis is a likely diagnosis

Shigellosis is a possible cause of profuse bloody diarrhoea as cholera and giardiasis are associated with watery diarrhoea. Trophozoites seen in acute amoebic dysentery, and the test is not 100% sensitive.

[Q: 838] OnExamination -
Gastroenterology

Which of the following is NOT true of a patient with ascites due to liver cirrhosis:

- 1- Spontaneous bacterial peritonitis is a recognised feature
- 2- The usual source of the ascitic fluid is mainly from the exudation from the surface of the liver
- 3- Hepatic intrasinusoidal pressure is elevated
- 4- Urinary sodium concentration is usually less than 10 mmol/l
- 5- Cardiac output is often elevated

Answer & Comments

Answer: 2- The usual source of the ascitic fluid is mainly from the exudation from the surface of the liver

Hepatocellular failure is associated with hyperdynamic circulation and systemic vasodilatation, with increased vascular capacitance. Most patients have sodium and water retention.

[Q: 839] OnExamination -
Gastroenterology

A 55-year-old female is referred by her GP with abnormal liver function tests. She is overweight but otherwise well. Liver biopsy is reported as showing evidence of non-alcoholic steatotic hepatitis(NASH).

Which of the following statements is correct concerning NASH?

- 1- Commoner in males than females
- 2- Is treated with urso-deoxycholic acid
- 3- Is associated with insulin resistance
- 4- Is treated with Rosiglitazone
- 5- The majority of patients will develop cirrhosis

Answer & Comments

Answer: 3- Is associated with insulin resistance

NASH is associated with increased prevalence of Insulin resistance/type 2 diabetes. Approximately 20% develop cirrhosis

It is more common in obese females and the treatment is weight reduction.

[Q: 840] OnExamination -
Gastroenterology

A study comparing contrast CT colonography with the reference technique of colonoscopy for large bowel carcinoma reveals the following data in 400 patients:

	CT Positive	CT Negative
Colonoscopy Positive	30	10
Colonoscopy negative	20	340

Which one of the following most accurately describes the performance of CT versus colonoscopy for the diagnosis of large bowel cancer?

- 1- There are 340 false negatives
- 2- There are 370 false negatives
- 3- There are 10 false positives
- 4- There are 20 false positives
- 5- There are 20 true negatives

Answer & Comments

Answer: 4- There are 20 false positives

There are 40 true positive patients identified by Colonoscopy with colon cancer and 10 of these are false negatives as identified by CT. There are 360 patients without the disease with 20 identified as having cancer with CT (false positives).

[Q: 841] OnExamination - Gastroenterology

A 54-year-old woman presented with an eighteen month history of chest pain and dysphagia for both solids and liquids. She smokes 20 cigarettes per day and drinks 16 units of alcohol per week. Clinical examination was normal.

What is the most likely diagnosis?

- 1- Achalasia.
- 2- Bronchial neoplasm.
- 3- Oesophageal neoplasm.
- 4- Oesophageal web.
- 5- Pharyngeal pouch.

Answer & Comments

Answer: 1- Achalasia.

A longstanding history of dysphagia to both solids and liquids suggests a functional rather than mechanical cause for the dysphagia. Hence a neoplasm or other obstructive lesion is unlikely. Chest pain is not a typical feature of a pharyngeal pouch. Achalasia, in which there is failure of oesophageal peristalsis and of relaxation of the lower oesophageal sphincter, typically causes the symptoms described above.

[Q: 842] OnExamination - Gastroenterology

A 36-year-old man presented with a three day history of bloody diarrhoea. He was afebrile and mildly icteric. Investigations revealed:

Haemoglobin 10.5 g/dL (13.0-18.0)

White cell count $19 \times 10^9/L$ (4-11)

Platelets $70 \times 10^9/L$ (150-400)

Serum urea 12.5 mmol/L (2.5-7.5)

Serum aspartate aminotransferase 90 IU/L (1-31)

Prothrombin time 12s (11.5-15.5)

Blood film fragmented red cells

What is the most likely cause of his illness?

- 1- Escherichia coli 0157 colitis
- 2- Ischaemic colitis
- 3- Leptospirosis
- 4- Salmonella enterocolitis
- 5- Ulcerative colitis

Answer & Comments

Answer: 1- Escherichia coli 0157 colitis

The combination of bloody diarrhoea, haemolytic anaemia, thrombocytopenia but normal clotting, and renal impairment suggests haemolytic-uraemic syndrome. This

is associated with E coli 0157 toxin most commonly.

[Q: 843] OnExamination -
Gastroenterology

Ten individuals are admitted to casualty with profuse vomiting after attending a retirement dinner in a Chinese restaurant. They all ate at roughly 7 pm and became ill at roughly midnight. Nine ate a mixture of dishes except one female who ate vegetarian dishes with her rice.

What is the most likely infective organism?

- 1- Salmonella enteritidis
- 2- Staphylococcus aureus
- 3- Escherichia coli
- 4- Clostridium perfringens
- 5- Bacillus cereus

Answer & Comments

Answer: 5- Bacillus cereus

This is a typical case of Bacillus cereus, with profuse vomiting which occurs approx 1-5 hrs after eating. In this case it is likely that the rice itself had been infected. Another possibility is Staph. aureus although this is less likely.

[Q: 844] OnExamination -
Gastroenterology

A 24-year-old woman who has a long history of ulcerative colitis and takes Mesalazine 3g per day discovers that she is 10 weeks pregnant. She is also a smoker of 15 cigarettes daily. She now presents with a deterioration of symptoms with six bloody stools per day.

Which one of the following statements is correct?

- 1- Azathioprine would be contraindicated
- 2- Initiating an elemental diet predisposes to foetal malnutrition
- 3- Mesalazine therapy should be withdrawn

4- Steroid therapy is contraindicated

5- Termination of the pregnancy is advised

Answer & Comments

Answer: 1- Azathioprine would be contraindicated

Azathioprine should not generally be started in pregnancy. Well controlled ulcerative colitis is more important for the baby from a nutritional point of view. An elemental diet simply contains pre-digested food and would not lead to fetal malnutrition. The safety of the 5-ASA drugs in pregnancy is best supported by the data on salazopyrine which has been available for the longest.

[Q: 845] OnExamination -
Gastroenterology

A 55 year-old man on no current treatment for his quiescent ulcerative colitis is found to have an ESR of 95 mm/hr.

Investigations show:

Haemoglobin	13.2 g/L
WCC	4.5
PLT	160
Corrected Calcium	2.58
IgG	25 (6-13)
IgA	1.8 (0.9-3)
IgM	1.6 (0.4-2.2).

What is the most appropriate next investigation?

- 1- Bone marrow trephine and aspiration.
- 2- Isotope bone scan.
- 3- Plasma immunoelectrophoresis.
- 4- Rectal biopsy.
- 5- X-Ray Skeletal survey.

Answer & Comments

Answer: 3- Plasma immunoelectrophoresis.

The ESR is not raised in quiescent UC. Hence, there must be another reason in this case. The only abnormal result given is a raised IgG. This suggests that myeloma is the diagnosis. Plasma immunoelectrophoresis, to look for an M band, is the most appropriate next investigation. A bone marrow trephine is the definitive investigation but is traumatic and painful to the patient and so is not the next investigation of choice.

[Q: 846] OnExamination - Gastroenterology

A 35-year-old obese Afrocarribean lady presents with mild jaundice. She claims to be a teetotaler ممتنع عن المسكرات and her BMI is 30 kg/m².

Investigations reveal the following results.

Haemoglobin 14g/dL

U+Es normal

Bilirubin 25 µmol/L (2-18)

AST 140IU/L (5-40)

Alanine transaminase 155 IU/L (5-40)

ALP 160 IU/L (50-110)

Random blood glucose 11.2 mmol/l (3.5-6)

Hepatitis A IgG positive

Hepatitis B and C screening negative

Anti-nuclear antibodies 1:16 titre

Ultrasound Abdomen reveals Hyperechogenic hepatic parenchyma

Liver Biopsy reveals lesions suggestive of alcoholic liver disease

On review of her notes, liver function tests performed 6 months previously showed similar values.

Which of the following is the most likely diagnosis?

- 1- Alcoholic liver disease
- 2- Autoimmune hepatitis
- 3- Non-alcoholic steatohepatitis

4- Primary biliary cirrhosis

5- Viral hepatitis

Answer & Comments

Answer: 3- Non-alcoholic steatohepatitis

This is a case of non-alcoholic steatohepatitis, the diagnosis of which is made only by histology of liver biopsy which shows lesions suggestive of ethanol intake in a patient known to consume less than 40g of alcohol per week. The diagnosis is supported by the presence of obesity, hyperglycaemia and hyperechogenic hepatic parenchyma. In alcoholic hepatitis, AST to ALT ratio is more than 1.

[Q: 847] OnExamination - Gastroenterology

A 61-year-old man has a 2 cm adenoma removed from his sigmoid colon. The biopsy results confirm an adenocarcinoma in situ with moderately differentiated dysplastic cells. The pathology report confirms total excision with clear resection margins.

What is the most appropriate follow up management for this patient?

- 1- Annual carcinoembryonic antigen (CEA)
- 2- Chemotherapy
- 3- No follow up
- 4- Regular follow up with colonoscopy
- 5- Regular follow up with no colonoscopy

Answer & Comments

Answer: 4- Regular follow up with colonoscopy

The first thing to note is the question is about planned management This patient has been picked up early and has had a tumour resected. His CEA would be normal and would not be expected to be elevated until the disease was quite established on the TNM

scale. However, this patients prognosis would be excellent, but he is by definition someone with increased risk. Therefore, he should continue to be reviewed with colonoscopy annually for at least two years.

[Q: 848] OnExamination - Gastroenterology

A 47-year-old man presents with confusion and drowsiness. A diagnosis of hepatic encephalopathy is suspected and treatment with lactulose is begun.

Which of the following concerning lactulose is true?

- 1- Absorbed from the gut
- 2- Causes hypermagnesaemia
- 3- Contraindicated in diabetes mellitus
- 4- Inhibits proliferation of ammonia-forming organisms in the gut
- 5- Reduces absorption of spironolactone

Answer & Comments

Answer: 4- Inhibits proliferation of ammonia-forming organisms in the gut

Lactulose, an osmotic diuretic causes hypomagnesaemia associated with diarrhoea, is not absorbed, does not affect the absorption of spironolactone and may be used in diabetics. It is used in patients with cirrhosis/hepatic encephalopathy to limit the proliferation of ammonia forming gut organisms and increase the clearance of protein load in the gut.

[Q: 849] OnExamination - Gastroenterology

Which of the following statements regarding jejunal biopsy is correct?

- 1- Electron microscopy is necessary to confirm the presence of villous atrophy

- 2- Sub-total villous atrophy is diagnostic of gluten-sensitive enteropathy and is not found in other conditions
- 3- It is contra-indicated over the age of 70 years
- 4- In tropical countries apparently healthy people have a mucosal structure which would be regarded as abnormal in Europe
- 5- It can be used to diagnose Whipple's disease

Answer & Comments

Answer: 5- It can be used to diagnose Whipple's disease

a- the villus atrophy may be seen with a magnifying glass

b- sub-total villus atrophy is seen in a number of conditions other than coeliac disease (i.e. Severe tropical sprue, cow's milk / soya sensitivity in children, gastroenteritis, Whipple's disease, hypogammaglobulinaemia, neomycin therapy, laxative abuse, Norwalk agent)

c- There is a group of patients who present with coeliac disease in older age, sometimes in their 90s. They present with iron deficiency anaemia, osteoporosis or weight loss.

d- They would not be 'healthy'.

[Q: 850] OnExamination - Gastroenterology

A 43-year-old female presents with abdominal pain and watery diarrhoea. She is taking ibuprofen for joint pains, and has been previously investigated for infertility. She was given a proton pump inhibitor by her GP for 6 weeks with no relief of her symptoms.

Investigations:

Haemoglobin	12.2g/dl
Calcium	2.86mmol/l
Albumin	42g/l

Phosphate 0.8mmol/l
 CRP 10mg/l
 Endoscopy multiple small duodenal ulcers
 H. pylori negative

What is the likely diagnosis?

- 1- Crohn's disease
- 2- Cushing's Syndrome
- 3- NSAID induced PUD
- 4- Multiple endocrine neoplasia
- 5- Small Bowel Lymphoma

Answer & Comments

Answer: 4- Multiple endocrine neoplasia

The CRP is not raised, making a diagnosis of Crohn's unlikely. The DUs have persisted despite a lengthy treatment with PPIs. Small bowel lymphoma is suggested by narrowing of the intestine lumen, resulting in paraumbilical pain, made worse by eating, with weight loss, vomiting and occasional intestinal obstruction. Small bowel lymphoma is diagnosed by contrast radiographs and intestinal biopsy. The most likely diagnosis here is MEN, likely to MEN1a (Wermer's Syndrome). Multiple DUs make a diagnosis of Zollinger Ellison's syndrome likely, due to Gastrinomas. Hypergastrinaemia may be the cause of the diarrhoea. There is also hypercalcaemia as a result of the parathyroid hyperplasia indicative of this condition. There may not necessarily be a family history, sporadic cases make up 10% of new cases. The infertility would fit with a prolactinoma.

[Q: 851] OnExamination - Gastroenterology

A 51-year-old male labourer presents with a haematemesis.

Which of the following features would categorise him into a high risk group?

- 1- A blood pressure of 134/88 mmHg

- 2- A pulse of 90 beats per minute
- 3- A plasma glucose of 7.2 mmol/l
- 4- A history of ischaemic heart disease
- 5- His age

Answer & Comments

Answer: 4- A history of ischaemic heart disease

There are a number of scoring systems which are available to stratify subjects with GI bleed in to high and low risk groups. The Rockall scoring system is based on age (higher the age the worse the prognosis), comorbidities (IHD), the presence of shock, and endoscopic abnormalities. The Canadian Consensus Conference Statement utilises a similar system incorporating Endoscopic factors including active bleeding, major stigmata of recent hemorrhage, ulcers greater than 2 cm in diameter, and the location of ulcers in proximity to large arteries. The Baylor Bleeding score attaches a score to pre- and post- endoscopic features. The Blatchford score is based on clinical parameters alone - elevated blood urea nitrogen, reduced haemoglobin, a drop in systolic blood pressure, raised pulse rate, the presence of melaena or syncope, and evidence of hepatic or cardiac disease

[Q: 852] OnExamination - Gastroenterology

A 19-year-old student presents with a fifteen week history of diarrhoea. He has lost 2 kg in weight, and has no recent travel abroad. A smear of a duodenal biopsy reveals many trophozoites.

What is the best treatment option?

- 1- Ciprofloxacin
- 2- Gluten free diet
- 3- Metronidazole
- 4- Prednisolone

5- Quinine

Answer & Comments

Answer: 3- Metronidazole

The diagnosis here is Giardiasis, caused by *Giardia lamblia*. *Giardia* has been reported as a cause of chronic diarrhoea. Most patients respond to oral metronidazole 250-400mg tds for 5 days.

[Q: 853] OnExamination -
Gastroenterology

A 29-year-old man presents with anaemia, bleeding tendency, diarrhoea and abdominal pain. Examination reveals a palpable mass in the right lower quadrant and anal skin tags.

What is the most likely underlying condition?

- 1- chronic pancreatitis
- 2- coeliac disease
- 3- crohn's disease
- 4- intestinal lymphoma
- 5- ulcerative colitis

Answer & Comments

Answer: 3- crohn's disease

Crohn's disease commonly presents with diarrhoea, abdominal pain and weight loss. It can affect the whole gastrointestinal tract, the commonest being ileocolitis. Anaemia is usually due to blood loss and less commonly B12/folate malabsorption. An abdominal mass is often palpable in presence of small bowel disease, which can lead to Vitamin K malabsorption. Anal tags, fissures, perianal fistulae and abscesses are associated with crohn's disease and not ulcerative colitis.

[Q: 854] OnExamination -
Gastroenterology

A woman had lunch at a Chinese restaurant. In the evening she presented with diarrhoea and

vomiting. There was no fever.

Which of the following is the likely cause of food poisoning in her case?

- 1- Bacillus cereus
- 2- Clostridium perfringens
- 3- Escherichia coli
- 4- Staphylococcus aureus
- 5- Yersinia enterocolitica

Answer & Comments

Answer: 1- Bacillus cereus

Bacillus cereus food poisoning is the general description, although two recognized types of illness are caused by two distinct metabolites. The diarrhoeal type of illness is caused by a large molecular weight protein, while the vomiting (emetic) type of illness is believed to be caused by a low molecular weight, heat-stable peptide. The onset of watery diarrhoea, abdominal cramps, and pain occurs 6-15 hours after consumption of contaminated food. Symptoms usually persist for 24 hours. The emetic type of food poisoning is characterized by nausea and vomiting within 0.5 to 6 hours after consumption of contaminated foods. Occasionally, abdominal cramps and/or diarrhoea may also occur. Duration of symptoms is generally less than 24 hours.

A wide variety of foods including meats, milk, vegetables, and fish have been associated with the diarrhoeal type food poisoning. The vomiting-type outbreaks have generally been associated with rice products. *Staphylococcus aureus* and *Clostridium perfringens* are associated with meat and *Yersinia enterocolitica* with milk

[Q: 855] OnExamination -
Gastroenterology

Which of the following is the commonest cause of traveller's diarrhoea?

- 1- Escherichia coli

- 2- Entamoeba histolytica
- 3- Giardia lamblia
- 4- Shigella flexneri
- 5- Yersinia enterocolitica

Answer & Comments

Answer: 1- Escherichia coli

Enterotoxigenic E Coli is the commonest cause of travellers diarrhoea and is usually a self limiting condition. Usually no treatment nor investigation is required for this brief diarrhoeal illness. Other causes that may be associated with prolonged diarrhoea include Giardia and amoebiasis. Chronic diarrhoea merits investigation.

[Q: 856] OnExamination - Gastroenterology

Which ONE statement is true regarding the treatment of iron deficiency anaemia:

- 1- iron is absorbed in the distal jejunum
- 2- absorption of iron is increased by ascorbic acid
- 3- sustained release iron is a useful way of giving larger doses
- 4- ferrous sulphate 200mg has less elemental iron than the same dose of ferrous gluconate
- 5- parenteral iron is indicated when the anaemia responds slowly to oral iron

Answer & Comments

Answer: 2- absorption of iron is increased by ascorbic acid

- 1 - iron is absorbed in the upper small intestine.
- 2 - absorption of oral iron is improved by ascorbic acid.

3 - sustained release preparations may improve tolerance of oral iron but do not aid absorption.

4 - ferrous sulphate has more elemental iron by mass.

5 - parenteral iron acts no faster than oral iron. It is indicated when oral iron cannot be tolerated or is not absorbed.

[Q: 857] OnExamination - Gastroenterology

A 65-year-old man was investigated for weight loss and dyspepsia. Endoscopic examination revealed an ulcerated lesion in the stomach and biopsy revealed the presence of a low grade mucosa-associated lymphoma with Helicobacter pylori. Further investigation with CT of chest and abdomen were normal as were bone marrow aspirate and trephine.

What is the best treatment option for this patient?

- 1- Eradication therapy for Helicobacter pylori
- 2- IV chemotherapy
- 3- Oral chlorambucil
- 4- Partial gastric resection
- 5- Radiotherapy

Answer & Comments

Answer: 1- Eradication therapy for Helicobacter pylori

This is a gastric MALT tumour. These are usually marginal zone B cell lymphomas and associated with an excellent prognosis. Low grade gastric MALT tumours associated with Helicobacter Pylori infection respond in over 80% to helicobacter eradication as the primary mode of treatment. Radiotherapy is considered but generally unnecessary.

[Q: 858] OnExamination -
Gastroenterology

A 24-year-old woman was referred with tiredness and intermittent bloody diarrhoea and a past history of cerebral venous thrombosis.

On examination, the sclera of the right eye was inflamed, and multiple mouth ulcers were noted. At the colonoscopy, which confirmed colitis, two large vulval ulcers were noted.

Which is the most likely diagnosis?

- 1- Behcet's disease.
- 2- Crohn's disease.
- 3- HIV infection
- 4- Syphilis
- 5- Ulcerative colitis.

Answer & Comments

Answer: 1- Behcet's disease.

A classical description of the presentation of Behcet's, with oral and genital ulceration, colitis and scleritis.

[Q: 859] OnExamination -
Gastroenterology

Which ONE of the following statements regarding colon cancer is correct:

- 1- In non-familial cases, gene mutations in the cancer cells are unusual
- 2- In familial cases the inheritance pattern is typically autosomal recessive
- 3- It occurs most commonly in the ascending colon
- 4- It is a characteristic feature of the Peutz-Jegher syndrome
- 5- In familial polyposis coli the increased cancer risk is due to inheritance of a mutated suppressor gene

Answer & Comments

Answer: 5- In familial polyposis coli the increased cancer risk is due to inheritance of a mutated suppressor gene

A- Quantitative and qualitative alterations in gene expression accumulate in colorectal cancer cells. These include alterations of pro-oncogene expression and chromosomal abnormalities (deletions at 17p and 18q are seen in 70% of colorectal carcinomas).

B- Both familial polyposis coli and Gardner's syndrome are autosomal dominant.

C- The rectum and sigmoid colon are the commonest sites.

D- Peutz-Jegher's syndrome is dominantly inherited pigmentation of skin and mucous membranes, and hamartomatous polyps in the stomach and larger intestine. The polyps only rarely undergo malignant change.

E- An allelic deletion of a putative tumour suppressor gene located 5q21-q22. FAP is an autosomal dominant disorder causing extensive adenomatous polyps of the colon and early onset colorectal cancer.

[Q: 860] OnExamination -
Gastroenterology

A 40-year-old man has a history of left-sided Crohn's colitis. Though, previously treated with steroids and mesalazine, he has had several relapses in the past year. The last relapse, treated with high doses of steroids, was complicated by gastric bleeding.

Investigations show:

Haemoglobin 10.8 g/L (13.0-18.0)

MCV 76 fL (80-96)

MCH 24 pg (28-32)

WBCs $10 \times 10^9/L$ (4-11)

Platelets $400 \times 10^9/L$ (150-400)

Serum total protein 70 g/L (61-76)

Serum albumin 30 g/L (37-49)

Serum CRP 30 mg/L(<10)

Abdo X-ray normal

Which of the following is the most appropriate management?

- 1- A trial of oral metronidazole for three months.
- 2- Total colectomy with ileostomy construction.
- 3- Total colectomy with pouch construction.
- 4- Treatment with azathioprine.
- 5- Treatment with oral budesonide.

Answer & Comments

Answer: 4- Treatment with azathioprine.

This patient has all the hallmarks of active Crohn's colitis that is failing to settle with first-line medical therapy.

The next step is a trial of azathioprine, which is used as a steroid-sparing agent. This is particularly relevant to this particular patient, as he has had a serious side-effect from previous steroid treatment. Metronidazole is rarely effective in the treatment of active Crohn's colitis. Given that Crohn's disease can recur following surgery, an operation should not be embarked upon without first a trial of the second-line medical therapies such as azathioprine, its metabolite 5-mercaptopurine, or infliximab.

[Q: 861] OnExamination - Gastroenterology

A 58-year-old man complains of tiredness, fever, weight loss, arthralgia and diarrhoea. Jejunal biopsy reveals flattened mucosa containing periodic acid-Schiff (PAS) positive macrophages.

What is the most likely diagnosis?

- 1- coeliac's disease
- 2- tuberculosis

- 3- tropical sprue
- 4- parasitic infection
- 5- whipple's disease

Answer & Comments

Answer: 5- whipple's disease

Whipple's disease is rare and affects most commonly middle-aged males. It can affect any organ, but dominated by involvement of small bowel, causing malabsorption. The organism (*Tropheryma whipplei*) can be identified both between and within abnormal macrophages, which stain magenta with PAS. Treat with prolonged antibiotics eg parenteral penicillin and streptomycin for 2 weeks, followed by 1 year of doxycycline.

[Q: 862] OnExamination - Gastroenterology

A 48-year-old woman complains of pruritis, steatorrhoea and bruising. On examination, she is jaundiced, pigmented with spider naevi and hepatosplenomegaly.

What is the most likely underlying diagnosis?

- 1- autoimmune hepatitis
- 2- primary biliary cirrhosis
- 3- alcoholic liver disease
- 4- alpha-1 antitrypsin deficiency
- 5- Wilson's disease

Answer & Comments

Answer: 2- primary biliary cirrhosis

She has clinical evidence of chronic liver disease and portal hypertension. The 2 main conditions causing pigmentation and chronic liver disease are primary biliary cirrhosis (PBC) and haemochromatosis. PBC is a chronic cholestatic inflammatory liver disease, the aetiology of which is probably autoimmune. It most commonly affects middle-aged women. There is jaundice with skin pigmentation, risk

of developing oesophageal varices and fat malabsorption, leading to deficiency of the vitamins A, D, E, K (hence osteomalacia and also bruising). Serum antimitochondrial antibody is positive in 95-99% cases.

[Q: 863] OnExamination - Gastroenterology

A 35-year-old woman with alcoholic cirrhosis is admitted with deteriorating encephalopathy and abdominal discomfort. An ascitic tap revealed a polymorphonuclear cell count of 350 cells per mm³.

Which of the following is the most appropriate therapy?

- 1- Intravenous amoxicillin
- 2- Intravenous cefotaxime
- 3- Intravenous metronidazole
- 4- Oral neomycin
- 5- Oral norfloxacin

Answer & Comments

Answer: 2- Intravenous cefotaxime

This lady has Spontaneous Bacterial Peritonitis as suggested by the typical history, ascites and raised polymorphonuclear count within the ascitic tap. It is most commonly seen in alcoholic cirrhosis and the causative organism is usually *Escherichia coli*, *Klebsiella*, *S. Pneumoniae* or *Enterococci*. (Compare this with the mixed growth seen in other forms of peritonitis). Sending some ascitic fluid in blood culture bottles increases the yield. Initial treatment is with broad spectrum antibiotics such as cefotaxime. Norfloxacin is recommended for short term prophylaxis.

[Q: 864] OnExamination - Gastroenterology

A 69-year-old male is seen in Outpatients. He reports weight loss of 1 stone over 3 months but his history is otherwise unremarkable. On

examination his abdomen is soft with no palpable masses.

A PR examination is normal.

His blood tests show:

Haemoglobin 8.0g/dl (12-16)

MCV 70fl (85-95)

Which of the following is the most appropriate investigation for this patient?

- 1- Abdominal X-ray and colonoscopy
- 2- CT scan of the abdomen and upper GI endoscopy
- 3- Sigmoidoscopy upper GI endoscopy
- 4- Ultrasound scan of abdomen and colonoscopy
- 5- Upper GI endoscopy and colonoscopy

Answer & Comments

Answer: 5- Upper GI endoscopy and colonoscopy

This man has weight loss and an unexplained microcytic anaemia. The likely site of blood loss is from the GI tract in absence of an alternative explanation. This may be due to an occult GI malignancy and, therefore, the initial investigations of choice are upper and lower GI endoscopy.

[Q: 865] OnExamination - Gastroenterology

In the diarrhoea associated with cholera toxin, there is activation of which of the following enzyme systems?

- 1- Adenylate cyclase.
- 2- ATP.
- 3- Guanylate cyclase.
- 4- Na-glucose co-transporter.
- 5- Na⁺/K⁺ ATPase pump.

Answer & Comments

Answer: 1- Adenylate cyclase.

Cholera toxin has two parts, A and B. B binds while A activates G protein, which activates adenylate cyclase. Elevated CAMP results in unrestricted chloride secretion from villous crypts.

[Q: 866] OnExamination - Gastroenterology

Which of the following statements is correct of hepatitis C virus infection?

- 1- Cell cultures of virus are routinely used to assess response to drug therapy
- 2- High antibody titres are an indication for therapy
- 3- Less than 5% of cases lead to chronic infection
- 4- More likely to be transmitted by the sexual route than hepatitis B virus
- 5- Treatment with ribavirin and interferon alpha is more effective than interferon alpha alone

Answer & Comments

Answer: 5- Treatment with ribavirin and interferon alpha is more effective than interferon alpha alone

In hepatitis C infection the criteria for treatment are abnormal liver function tests and detectable hepatitis C RNA in plasma, with evidence of moderate inflammation on liver biopsy. Response to therapy is determined by normalisation of hepatic transaminases and undetectability of hepatitis C RNA in plasma. Hepatitis C is generally transmitted by inoculation or vertically from mother-to-child. In contrast to hepatitis B, sexual transmission is uncommon. Around 85% of acute hepatitis C infections lead to chronic infection. Treatment with interferon alpha alone has around a 10-15% success rate

in achieving long-term undetectability of plasma hepatitis C RNA. Combination treatment with ribavirin and interferon alpha has been found to have approximately a 45% success rate.

[Q: 867] OnExamination - Gastroenterology

A 33-year-old man with chronic hepatitis C is admitted with general deterioration. He has missed many of his previous outpatient appointments and currently is not receiving any treatment. On examination he is generally unwell with a temperature of 37.8C, blood pressure of 110/72 mmHg and appears jaundiced. His investigations reveal:

Serum Na 133 mmol/l

Serum potassium 4.3 mmol/l

Serum Urea 21 mmol/l

Serum Creatinine 336 micromol/l

bilirubin 78 micromol/l (10-20)

AST 92 iu/l (10-40)

Alk Phosphatase 267 (50-100)

Albumin 30 (33-42)

Urine sodium 15 mmol/l

What is the likely diagnosis?

- 1- Abdominal tuberculosis
- 2- Hepatocellular carcinoma
- 3- Hepatorenal syndrome
- 4- Mixed essential cryoglobulinaemia
- 5- Spontaneous bacterial peritonitis

Answer & Comments

Answer: 3- Hepatorenal syndrome

The abnormal urea and creatinine plus the low urine sodium suggest a diagnosis of hepatorenal syndrome. Fluid balance is very difficult in these patients but some respond to treatment with IV glypressin which improves kidney perfusion.

[Q: 868] OnExamination -
Gastroenterology

A 16-year-old boy with cystic fibrosis presents with abdominal pain.

Which of the following is most likely to be the cause?

- 1- Ulcerative colitis
- 2- Irritable Bowel Syndrome
- 3- Pyelonephritis
- 4- Meconium Ileus Equivalent Syndrome
- 5- Renal Calculi

Answer & Comments

Answer: 4- Meconium Ileus Equivalent Syndrome

Meconium ileus equivalent or distal intestinal obstruction syndrome occurs in older children and adults with CF and presents with colicky abdominal pain, distension, vomiting and failure to pass faeces. The plain AXR confirms small bowel obstruction. Initial management includes rehydration with IV fluids and oral N-acetyl cysteine. Other GI complications of / associations with CF include liver cirrhosis, gall bladder disease, pancreatitis, peptic ulceration, hiatus hernia, coeliac disease and Crohns disease.

[Q: 869] OnExamination -
Gastroenterology

A 25-year-old man, who had a long history of heavy alcohol intake is admitted with nausea and frequent vomiting four hours after a meal in a restaurant. During review in the A+E he vomits a cupful of blood.

What is the cause of his haemetemesis?

- 1- duodenal ulceration
- 2- Haemorrhagic Gastritis
- 3- Mallory-Weiss tear
- 4- oesophageal varices
- 5- oesophagitis

Answer & Comments

Answer: 3- Mallory-Weiss tear

Persistent vomiting can eventually lead to small tears in the oesophagus leading to the vomiting of red blood. Varices would produce large volumes of blood (much more than just a cupful).

[Q: 870] OnExamination -
Gastroenterology

A routine ultrasound at 18 weeks gestation in a diabetic mother reveals a male foetus with an endocardial cushion defect. Other abnormalities include increased nuchal thickening and a "double bubble" sign.

Which of the following conditions is most likely to have contributed to this set of findings:

- 1- Maternal use of ACE inhibitor
- 2- Marfan syndrome
- 3- Maternal folate deficiency
- 4- Trisomy 21
- 5- Congenital syphilis

Answer & Comments

Answer: 4- Trisomy 21

Diabetic mothers are more likely to have children with congenital abnormalities depending on pre-conception, and first trimester blood sugar control. 40% of Down's syndrome babies have atrioventricular septal defects as in this foetus. The double bubble sign suggests duodenal atresia which again suggests Down's syndrome. GI malformations occur in 6% of Down's patients - most commonly duodenal atresia and Hirschsprungs disease.

[Q: 871] OnExamination -
Gastroenterology

An 80-year-old female presents with confusion associated with a chest infection.

She received standard treatment, and four days later she developed green, then bloody diarrhoea.

Which of the following organisms is most likely to be responsible for her diarrhoea?

- 1- Campylobacter jejuni
- 2- Clostridium difficile
- 3- Escherichia coli 0157
- 4- Methicillin-resistant Staphylococcus aureus
- 5- Vancomycin-resistant enterococcus

Answer & Comments

Answer: 2- Clostridium difficile

This is typical of Clostridium infection with pseudomembranous colitis induced by prior treatment with broad spectrum antibiotics such as cefuroxime, augmentin and the macrolides. It is treated with oral vancomycin/metronidazole.

[Q: 872] OnExamination - Gastroenterology

45-year-old gentleman presents with dyspepsia of 5 months duration and loss of weight. Examination reveals mild pallor and slight epigastric tenderness. Gastroscopy reveals 5-mm posterior ulcer in the first part of duodenum and 2-cm mass on lesser curve of the stomach. Biopsy of the mass reveals mucosa-associated lymphoid tumour confined to gastric mucosa. He has tested positive for H. pylori infection.

Which of the following treatment options will be appropriate for him?

- 1- Chemotherapy
- 2- H. Pylori eradication
- 3- Proton pump inhibitor
- 4- Radiotherapy
- 5- Surgery

Answer & Comments

Answer: 2- H. Pylori eradication

Lymphomas restricted to the gastric mucosa usually disappear when H. pylori is eradicated. These lesions are less likely to respond to H. pylori eradication alone if they extend beyond the gastric mucosa. Chemotherapy or surgical excision may then be indicated. Duodenal ulcer will also disappear with H. pylori eradication.

[Q: 873] OnExamination - Gastroenterology

A 63-year-old patient with known alcohol related cirrhosis presented with ascites, abdominal tenderness and peripheral oedema. A diagnostic tap revealed a neutrophil count of 400/ mm³ (normal <250/mm³).

Which of the following would be of most immediate benefit?

- 1- fluid restriction and a no added salt diet
- 2- intravenous antibiotics
- 3- oral spironolactone
- 4- therapeutic paracentesis
- 5- trans-jugular intrahepatic porto-systemic shunt

Answer & Comments

Answer: 2- intravenous antibiotics

This man has spontaneous bacterial peritonitis (SBP). Appropriate treatment is IV antibiotics. He is likely to have a decreased intravascular volume and require IV albumin as volume expansion. Fluid restriction, diuretics, or large volume paracentesis are likely to cause further hypovolaemia and precipitate renal failure. There is no stated indication for a TIPSS, indications are: diuretic resistant ascites, intractable portal hypertensive bleeding and hepato-renal failure.

[Q: 874] OnExamination -
Gastroenterology

Which of the following statements is characteristic of acute hepatitis B infection?

- 1- Most patients present with splenomegaly.
- 2- It confers immunity to hepatitis A.
- 3- It commonly presents with distal joint arthritis.
- 4- There is increased infectivity in the presence of the Hep B e antigen.
- 5- Pruritis is an important early symptom.

Answer & Comments

Answer: 4- There is increased infectivity in the presence of the Hep B e antigen.

Clinical features of hepatitis B are as follows:

1. Most are asymptomatic.
2. Symptoms: Lethargy, anorexia, arthralgia, rash (any type), papular acrodermatitis (Gianotti Crosti), polyarthritis, glomerulonephritis, aplastic anaemia. 25 % have jaundice.
3. Complications: ?Acute fulminant hepatitis. ?Chronic hepatitis. ?Membranous glomerulonephritis. Hepatitis E antigen is present in the acute phase and indicates a highly infectious state. Pruritis is characteristic of chronic hepatitis.

[Q: 875] OnExamination -
Gastroenterology

A 58-year-old man presents to your clinic with dysphagia for solids for the past three months. He also complains of weight loss and loss of appetite. There is no other past medical history, apart from symptoms of indigestion and heartburn for the past five years. He regularly takes Gaviscon and Rennie tablets. He is a heavy smoker and a regular drinker. He undergoes endoscopy, which reveals a small tumour at the lower end of the oesophagus.

What is the most likely aetiological cause for the tumour?

- 1- Alcohol
- 2- Barrett's oesophagus
- 3- Helicobacter pylori
- 4- Oesophageal candidiasis
- 5- Oesophageal pouch

Answer & Comments

Answer: 2- Barrett's oesophagus

The history is suggestive of gastro oesophageal reflux for the past 5 years, which can predispose to columnization of the oesophageal mucosa known as Barrett's oesophagus, this is a premalignant state and 3 yearly surveillance endoscopies are recommended. The development of dysphagia for solids and weight loss suggests the development of oesophageal carcinoma.

[Q: 876] OnExamination -
Gastroenterology

An asymptomatic 40-year-old female underwent an abdominal ultrasound scan as part of a clinical trial and was noted to have gallstones but entirely normal liver function tests.

Which one of the following is the most appropriate management?

- 1- Chenodeoxycholic acid
- 2- Laparoscopic cholecystectomy
- 3- Lithotripsy
- 4- Observation
- 5- Ursodeoxycholic acid

Answer & Comments

Answer: 4- Observation

This patient is asymptomatic and does not require any treatment at present. If it ain't broken don't fix it is the general rule. There is

no proven role for the use of oral drugs to try and reduce the formation of gallstones. The only definitive treatment would be a cholecystectomy but that is not generally offered for asymptomatic gallstones.

[Q: 877] OnExamination -
Gastroenterology

A 50-year-old ex-footballer with a long history of alcohol excess presents with epigastric pain.

Which of the following suggests a diagnosis of peptic ulceration rather than chronic pancreatitis?

- 1- Back pain
- 2- Exacerbation with alcohol
- 3- Loose stool
- 4- Relieved by food
- 5- Weight loss

Answer & Comments

Answer: 4- Relieved by food

Relief with food suggests peptic (and specifically) duodenal ulceration. It is likely that food would precipitate the pain of chronic pancreatitis.

Loose stool is suggestive of pancreatitis/malabsorption. Pain referred to the back occurs in both situations and hence not suggestive.

Weight loss can occur in both gastric ulcers and pancreatitis and not very suggestive. Alcohol may well exacerbate both types of pain.

[Q: 878] OnExamination -
Gastroenterology

A 60-year-old woman with known alcoholic liver cirrhosis presents with vague abdominal pains, malaise and nausea. She has been abstinent since she was diagnosed eight

months ago. On examination she had moderate ascites and mild, generalised abdominal tenderness.

Investigations

Haemoglobin 11.2 g/dL (11.5 - 16.5)

WCC $15 \times 10^9/L$ (4 - 11)

prothrombin time 21 s (<15s)

serum albumin 28 g/L (37 - 49)

serum total bilirubin 56 $\mu\text{mol/L}$ (1 - 22)

ascitic fluid protein 26 g/L

ascitic fluid amylase normal

ascitic fluid white cell count $500 \times 10^9/L$

What is the most likely reason for her current problem?

- 1- hepatic vein thrombosis
- 2- pancreatic pseudocyst rupture
- 3- portal vein thrombosis
- 4- primary liver cancer
- 5- spontaneous bacterial peritonitis

Answer & Comments

Answer: 5- spontaneous bacterial peritonitis

The high white cell count in the ascites makes spontaneous bacterial peritonitis (SBP) much more likely than Budd Chiari Syndrome (BCS), PVT, HCC, or a ruptured pancreatic pseudocyst. Abdominal pain is often only mild, or even absent in SBP, with patients often presenting with otherwise unexplained hepatic decompensation.

[Q: 879] OnExamination -
Gastroenterology

A 32-year-old female presents with pruritis and jaundice. She is 30 weeks gestation in her first pregnancy. Two weeks earlier she had been treated by the ENT surgeons after presenting to A+E with intractable nose bleeds.

The Liver Function Tests are shown below:

ALT 72 U/L (5-40)
 Alkaline phosphatase 700 U/L (30-110)
 Bilirubin 80 μ mol/L (1-18)
 Serum bile acids 100 times normal titre.

Which of the following statements is correct concerning this patient?

- 1- ALP does not increase in a normal pregnancy
- 2- Maternal hepatic blood flow does not increase in pregnancy
- 3- Treatment options include IV N-acetylcysteine
- 4- Varices are diagnostic of liver disease in pregnancy
- 5- Viral hepatitis is the likely diagnosis

Answer & Comments

Answer: 2- Maternal hepatic blood flow does not increase in pregnancy

The diagnosis here is Intrahepatic Cholestasis which presents with markedly elevated serum bile acids (cholelyglycine). It presents in the 2nd or 3rd trimester, and usually the alkaline phosphatase is 7-10 times normal, with raised ALT, AST and bilirubin. Cardiac output and blood volume increase in pregnancy, but hepatic blood flow does not. Treatment options include ursodeoxycholic acid, cholestyramine, Phenobarbital and vitamin K to treat the coagulopathy. ALP rises in pregnancy but not to this extent. The placenta is the source of the raised ALP. Viral hepatitis is the commonest cause of jaundice in pregnancy, but the elevated bile acids make this unlikely in this case.

[Q: 880] OnExamination - Gastroenterology

Which of the following is most likely to be reversible following venesection in a 45-year-old male with haemochromatosis?

- 1- Arthropathy
- 2- Cardiomyopathy
- 3- Cirrhosis
- 4- Diabetes Mellitus
- 5- Hypopituitarism

Answer & Comments

Answer: 2- Cardiomyopathy

Disorders that are potentially reversible in haemochromatosis include the dermal pigmentation and cardiomyopathy. Similarly there are improvements in LFTs. However, diabetes, cirrhosis, hypogonadism and arthropathy are usually irreversible.

[Q: 881] OnExamination - Gastroenterology

A 56-year-old man from Thailand presented with abdominal pain and a mass in the right upper quadrant. He reported that he had been diagnosed with viral hepatitis several years previously.

Investigations showed:

Serum alpha-fetoprotein 13,500 IU/L (< 10)

What is the most likely underlying viral infection?

- 1- Hepatitis A virus
- 2- Hepatitis B virus
- 3- Hepatitis C virus
- 4- Hepatitis D virus
- 5- Hepatitis E virus

Answer & Comments

Answer: 2- Hepatitis B virus

Very difficult! The patient has chronic viral hepatitis and presents with a hepatoma. The underlying cause must be either HBV or HCV. There is a higher prevalence of HBV in the Far East and since his country of origin is the only

other detail that gives a clue to the cause of his hepatitis, the most likely viral agent is HBV.

[Q: 882] OnExamination -
Gastroenterology

Which of the following is true concerning a hepatitis E infection?

- 1- It can be transmitted with hepatitis B.
- 2- It is a recognised cause of chronic liver disease.
- 3- CT scan of the liver with contrast shows diagnostic appearances.
- 4- The incidence of chronic liver disease is reduced by administration of alpha interferon.
- 5- It does not result in a carrier state.

Answer & Comments

Answer: 5- It does not result in a carrier state.

Five hepatitis viruses form a heterogeneous group causing similar clinical illnesses. Hepatitis A, C, D, and E are all RNA viruses coming from 4 different families; and hepatitis B is a DNA virus. Hepatitis A & E cause acute illness, with the former causing most hepatitis in childhood and hepatitis E being very rare. Hepatitis B, C, and D cause chronic morbidity and mortality, with B causing a third of cases, hepatitis C a fifth of cases, and D being very rare. Hepatitis D illness cannot occur without B as a helper virus. Hepatitis B can be treated with interferon-alpha, which improves liver disease.

[Q: 883] OnExamination -
Haematology

A 20-year-old man presented to hospital two days after returning from visiting his family in Bangladesh. Within a day of his return to the UK, he suddenly developed profuse watery diarrhoea.

He says there had been an outbreak of diarrhoea in his family's village in the week before his return.

Stool culture revealed a growth of *Vibrio cholerae*.

Which one of the following blood types is associated with the greatest susceptibility to severe cholera?

- 1- Blood Group A
- 2- Blood Group AB
- 3- Blood Group B
- 4- Blood Group O
- 5- Rhesus -ve

Answer & Comments

Answer: 4- Blood Group O

"Individuals with blood group O are more susceptible than other individuals to severe cholera, although the mechanism underlying this association is unknown."

Infect Immun. 2005 Nov;73(11):7422-7

[Q: 884] OnExamination -
Haematology

A 36-year-old female who is on warfarin after suffering a deep vein thrombosis, presents with an INR of 8.2 and a conjunctival haemorrhage.

The blood pressure is 125/55 mmHg, heart rate is 65 bpm and the ECG reveals a normal sinus rhythm.

Which of the following is the most appropriate treatment for this patient?

- 1- FFP
- 2- Factor VII
- 3- Oral vitamin K 1mg
- 4- Prothrombin complex concentrate
- 5- Stop warfarin only

Answer & Comments

Answer: 3- Oral vitamin K 1mg

A conjunctival bleed is defined as a minor bleed, and current guidelines suggest that oral or IV vitamin K together with the omission of warfarin, is the treatment of choice. Local guidelines should also be available. One must always weigh up the risks and benefits of reversing the anticoagulation. The patient described is at low risk if the warfarin induced coagulopathy is reversed. There is no suggestion from the ECG and the haemodynamic status that there is pulmonary embolus.

Major bleeds are defined as intraorbital, intracranial, retroperitoneal or muscular bleeding causing compartment syndrome. Any acute bleeding with BP<90mmHg, oliguria or Hb drop to less than 9g/l, also count as major bleeding episodes and require aggressive reversal of the coagulopathy with vitamin K, stopping warfarin and prothrombin complex concentrate or FFP.

[Q: 885] OnExamination -
Haematology

A 72-year-old male presents with a five day history of cough, dyspnoea and fever. His chest X-ray shows a left basal consolidation.

His Full Blood Count shows:

- Haemoglobin 11 g/dL (13.0-16.5)
- White cell count $30 \times 10^9/L$ (4-11)
- Neutrophils $10 \times 10^9/L$ (2-7)
- Lymphocytes $20 \times 10^9/L$ (1-4)
- Monocytes $1 \times 10^9/L$ (0-0.8)

Eosinophils $0.4 \times 10^9/L$ (0.04-0.4)

Basophils $0.1 \times 10^9/L$ (0-0.1)

Which one of the following is the most appropriate test to establish the diagnosis?

- 1- Bone marrow aspirate
- 2- Bone marrow cytogenetics
- 3- CT abdomen
- 4- Immunophenotyping of white cells
- 5- Sputum cytology and AFB

Answer & Comments

Answer: 4- Immunophenotyping of white cells

Apart from the mild neutrophilia, which could be explained by the infection, the significant abnormality on the FBC is the lymphocyte count. Such a high lymphocyte count could be suggestive of a lymphoproliferative disorder such as chronic lymphocytic leukaemia. The best way to diagnose these is immunophenotyping of the blood- non invasive and will give a diagnosis.

The patient may have lymphadenopathy, splenomegaly- which would show on CT, but no diagnosis can be made from this. A bone marrow is invasive, and the BM is sometimes not involved in low grade lymphoproliferative disorders and similarly there may be no cytogenetic abnormality.

The FBC is not suggestive of TB or malignancy, therefore sputum examination would not be useful.

[Q: 886] OnExamination - Haematology

An 84-year-old woman presented with tiredness. On examination, she was anaemic but had no palpable splenomegaly. Investigations revealed a haemoglobin of 9.7 g/dL (11.5 - 16.5). She was commenced on oral iron therapy for one month and her haemoglobin remained unchanged. Further investigations revealed:

MCV 102 fL (80 - 96)

blood film marked anisopoikilocytosis

serum ferritin 70 ug/L (15 - 300)

Vitamin B₁₂ 280 ng/L (160 - 760)

red cell folate 230 ug/L (160 - 640)

serum urea 9.1 mmol/L (2.5-7.5)

serum creatinine 150 umol/L (60 - 110)

What is the most likely diagnosis?

- 1- aplastic anaemia
- 2- anaemia due to renal disease
- 3- hypothyroidism
- 4- iron deficiency anaemia
- 5- sideroblastic anaemia

Answer & Comments

Answer: 5- sideroblastic anaemia

Idiopathic sideroblastic anaemia is a member of the myelodysplastic syndromes. In this condition, the red blood cells are normal or macrocytic and there is anisocytosis and poikilocytosis on the peripheral films. This isn't iron deficiency anaemia as the ferritin is normal and a microcytic anaemia would be expected. A normochromic normocytic anaemia is expected in renal disease (epo deficiency). Hypothyroidism may cause a slight elevation of MCV but no anisopoikilocytosis is evident.

[Q: 887] OnExamination - Haematology

A 26-year-old man presents with dark urine, especially in the early morning. Further investigations show that he has haemoglobinuria and haemolytic anaemia. A diagnosis of paroxysmal nocturnal haematuria is made.

What is the likely mechanism underlying this condition?

- 1- aberrant fusion of 2 genes

- 2- impaired protein degradation
- 3- over expression of cellular oncogene
- 4- post-translational modification
- 5- telomere shortening

Answer & Comments

Answer: 4- post-translational modification

Posttranslational modification by the GPI glycolipid anchor is essential for the surface expression of many membrane proteins. Defect of GPI biosynthesis due to somatic mutation in the hematopoietic stem cell is the basis for an acquired genetic disease, paroxysmal nocturnal haemoglobinuria. The other mechanisms are associated with various other diseases.

[Q: 888] OnExamination -
Haematology

Concerning immune cell antigen receptors, which of the following statements is false?

- 1- Affinity maturation of the B-cell receptor is an important process initiated during the primary immune response
- 2- IgD are surface receptors of B-lymphocytes
- 3- In normal individuals T- lymphocytes with T-cell receptors (TCR) that recognize auto-antigens are all deleted to prevent autoimmunity
- 4- TCRs with different antigen specificities can be co-expressed on a single T lymphocytes
- 5- The antigen specificity of the T-cell receptor is generated during development

Answer & Comments

Answer: 3- In normal individuals T-lymphocytes with T-cell receptors (TCR) that recognize auto-antigens are all deleted to prevent autoimmunity

T- and B-lymphocytes express receptors on their surface that recognise antigen in a

specific manner. Each individual lymphocyte expresses a single type of receptor with unique specificity. The receptor on the B-lymphocyte is membrane bound immunoglobulin (IgM and IgD isotype) and recognises particulate antigen, whilst the TCR is a heterodimer that recognise peptide fragments presented by MHC molecules.

The antigen specificity of T- and B- cells is generated during development by recombination of gene segments encoding the variable domains (antigen recognition domains) of immune receptors. These gene recombinations are random and maturing lymphocytes that express auto-reactive receptors are then deleted or rendered anergic.

These processes take place in the thymus (T-lymphocytes) and in the bone marrow (B-lymphocytes). However, not all autoreactive lymphocytes are deleted during development. In the case of T-lymphocytes, not all proteins are expressed in the thymus, and those that are present only in the periphery or at certain stages of development will encounter mature T-cells that can respond to them. Thus, autoreactive T-cells exist in the periphery and other mechanisms are responsible for the protection of the body against autoimmunity. Affinity maturation refers to the process of progressive development of immunoglobulin with higher affinity to the antigen. This occurs in the germinal centres of lymphoid organs during the evolution of the humoral response and is accomplished by hypermutation of the variable region genes. T-cells with dual specificities have been reported although their function is unknown.

[Q: 889] OnExamination -
Haematology

In porphyria, which of the following is least likely to precipitate an acute attack:

- 1- Menstruation
- 2- Aspirin

- 3- Phenytoin
- 4- Thiopentone
- 5- Starvation

Answer & Comments

Answer: 2- Aspirin

Porphyria is a group of diseases characterised by excess production and excretion of porphyrins and their precursors. They are caused by enzyme defects within the haem metabolic pathway. Stress, infection, pregnancy, menstruation, starvation and certain drugs may precipitate acute attacks. Definite precipitants include sulphonamides, barbiturates and phenytoin.

[Q: 890] OnExamination - Haematology

Anti-neutrophilic cytoplasmic autoantibodies:

- 1- positive only in Wegener's syndrome associated with renal disease
- 2- cause neutropenia in SLE
- 3- present in inflammatory bowel disease
- 4- increased in systemic lupus erythematosus
- 5- ANCA positive glomerulonephritis characteristically causes nephrotic syndrome

Answer & Comments

Answer: 3- present in inflammatory bowel disease

85% of untreated subjects with Wegener's will have c-ANCA, and those with limited disease are less likely to have positive serology. p-ANCA is present in approximately 70% with ulcerative colitis and less than 20% of Crohn's patients. Neither p nor c-ANCA is typical of SLE. Initial renal damage causes proteinuria (focal proliferative glomerulonephritis) but renal function can deteriorate rapidly, with

development of acute focal necrotising glomerulonephritis).

[Q: 891] OnExamination - Haematology

A 28-year-old pregnant woman is being treated for a deep vein thrombosis with unfractionated heparin.

A recent blood test shows:

Haemoglobin 9.8 g/dL

White Cell Count $9.5 \times 10^9/L$

Platelets $35 \times 10^9/L$

What would be the best course of action for this woman?

- 1- Change to hirudin
- 2- Change to low molecular weight heparin
- 3- Change to warfarin
- 4- Danaparinoid
- 5- No change in treatment and observe

Answer & Comments

Answer: 4- Danaparinoid

This patient appears to have Heparin Induced Thrombocytopaemia. When HIT is suspected, heparin treatment should be discontinued and alternative anticoagulation should be started. The heparinoid danaparoid appears to be the drug of choice for acute treatment and prophylaxis because of its low placental permeability. Hirudin should only be used when either cross-reactivity with heparin-induced antibodies or cutaneous allergy against heparinoids are observed.

[Q: 892] OnExamination - Haematology

A 53-year-old woman presents with a six month history of recurrent facial and tongue swelling. She associated the attacks with consuming certain food additives and with contact with some cosmetics and cleaning

fluids. Her only regular medication was hormone replacement therapy.

Investigations reveal:

total serum IgE 145 kU/L (0-120)

serum C3 105 mg/dL (65-190)

serum C4 35 mg/dL (15-50)

What is the most likely diagnosis?

- 1- C1 esterase inhibitor deficiency
- 2- chemical intolerance
- 3- food allergy
- 4- idiopathic angioedema
- 5- mastocytosis

Answer & Comments

Answer: 3- food allergy

The history suggests atopy which is confirmed by the mildly elevated IgE concentration and normal C4 and C3 concentrations.

Hereditary or acquired angioedema is unlikely given the normal C4 and the history occurs late. Also the patient herself has noticed a link with food - food allergy is usually easier to diagnosis in adults. The cosmetics (chemical intolerance) are unlikely and the clinical history does not fit mastocytosis.

[Q: 893] OnExamination - Haematology

A 78-year-old female who is on warfarin for atrial fibrillation presents with melaena.

The blood pressure is 90/60 mmHg and the heart rate 100 bpm. Investigations show:

Haemoglobin 9g/l (12-16)

MCV 87 fl (83-95)

INR 7.2

A PR examination confirms melaena.

Which is the best option for correcting the coagulopathy?

- 1- FFP

- 2- IV Vitamin K

- 3- Stop warfarin and give IV Vitamin K

- 4- Stop warfarin and give IV Vitamin K and Prothrombin complex concentrate

- 5- Stop warfarin

Answer & Comments

Answer: 4- Stop warfarin and give IV Vitamin K and Prothrombin complex concentrate

This patient is hypotensive and tachycardic with melaena suggesting a major bleeding episode on warfarin. In these circumstances, current guidelines suggest stopping warfarin, giving IV vitamin K, and either FFP, or Prothrombin complex concentrate. Local guidelines will be available, and if in doubt consult with the haematologist on call. FFP may not completely reverse the effects of warfarin, so it may now be preferable to consider Prothrombin complex concentrate (PCC) if available.

The rate of fatal haemorrhage in patients receiving warfarin approaches 1%. It is therefore essential that knowledge regarding the reversal of warfarin coagulation is serviceable.

[Q: 894] OnExamination - Haematology

A 25-year-old female with a history of type 1 Von Willebrand's disease is referred for an opinion. She is to have a cervical cone biopsy and the admitting team are concerned about her clotting.

You find that she has a past history menorrhagia and has had two dental extractions as an adolescent that were uncomplicated.

What is the most useful test to assess her bleeding tendency?

- 1- Activated partial thromboplastin time
- 2- Bleeding time

- 3- Plasma factor VIII activity
- 4- Platelet aggregation
- 5- Prothrombin time

Answer & Comments

Answer: 3- Plasma factor VIII activity

In Type I vWD the PT and platelet aggregation will be normal. Bleeding time, APTT and FVIIIc are likely to be abnormal. The bleeding time would be a good screening test, but as we already know she has Type I vWBD it will not give a quantitative measurement of her bleeding tendency.

Similarly APTT will not be that useful. The most useful test in practice is to do the VWB Antigen and activity(RICOF); But you would also do FVIIIc as this is also low in vWD.

[Q: 895] OnExamination -
Haematology

Which of the following statements is true of sickle cell disease?

- 1- a painful shoulder joint will respond to intra-articular corticosteroid injection
- 2- oral iron supplements are required
- 3- symptoms of anaemia are usually limiting when Hb equals 8 g/dl
- 4- there is often an inability to concentrate urine
- 5- the spleen is frequently enlarged

Answer & Comments

Answer: 4- there is often an inability to concentrate urine

There is a tendency to iron overload in sickle cell disease and therefore iron therapy is not usually indicated.

The spleen is decreased in size after 6 months of age.

Blood transfusion is not indicated since anaemia is usually only symptomatic below 7g/dl - oxygen is released more readily from erythrocytes.

Intra-articular steroids should be avoided. Bone disease in sickle cell disease consists of aseptic necrosis, acute infarction and osteomyelitis so steroids will be harmful.

[Q: 896] OnExamination -
Haematology

A 75-year-old man has a history of Chronic Lymphocytic Leukaemia. He has had treatment with several courses of chemotherapy and has now been admitted to hospital with pneumonia. His past medical history revealed that he had suffered several previous upper respiratory tract infections over the previous six months.

Which of the following components of his immune system is likely to be deficient?

- 1- Complement
- 2- Immunoglobulin G
- 3- Macrophages
- 4- Mast cells
- 5- T lymphocytes

Answer & Comments

Answer: 2- Immunoglobulin G

CLL is commonly complicated by panhypogammaglobulinaemia. Although IV immunoglobulin prevents recurrent infections it does not prolong survival.

[Q: 897] OnExamination -
Haematology

A patient with end stage renal disease is receiving haemodialysis and erythropoietin.

Which of the following does Erythropoietin therapy cause?

- 1- Benign intracranial hypertension

- 2- Myositis
- 3- Hypotension
- 4- Seizures
- 5- Osteoporosis

Answer & Comments

Answer: 4- Seizures

Hypertension is a frequent problem associated with erythropoietin and may induce seizures. A particular symptom is the onset of sudden stabbing migraine-like headache and should raise awareness to the possibility of hypertensive crisis. Other adverse effects of treatment with erythropoietin include hyperkalaemia in uraemic patients, increased PCV (especially with misuse by normal individuals), thrombocythaemia, shunt thrombosis, induction of iron deficiency, skin rashes, urticaria and flu-like illness.

[Q: 898] OnExamination -
Haematology

Which of the following statements is most true regarding polycythaemia rubra vera (PRV)?

- 1- The diagnosis of PRV is based on a high red cell mass, normal oxygen saturations and splenomegaly
- 2- PRV may be characterised by a raised packed cell volume and decreased plasma volume
- 3- PRV is often associated with hypertension and smoking
- 4- PRV is usually associated with a high haemoglobin, but with neutropenia and thrombocytopenia
- 5- Venesection treatment will improve long term survival rates

Answer & Comments

Answer: 1- The diagnosis of PRV is based on a high red cell mass, normal oxygen saturations and splenomegaly

The diagnosis of PRV is based on exactly what is stated in stem A of this question - high red cell mass, normal oxygen saturations and splenomegaly. A decreased plasma volume causing a raised PCV is known as apparent or spurious polycythaemia. This may be associated with hypertension or smoking. PRV is usually associated with a raised haemoglobin, and often with a high platelet count and white cell count. Venesection will lessen the rates of thrombotic complications, but there is no evidence that venesection improves long term survival rates.

[Q: 899] OnExamination -
Haematology

Which if the following is the mechanism of action of warfarin?

- 1- Activation of gamma-glutamyl carboxylase
- 2- Chelation of calcium
- 3- Inhibition of activated factor X
- 4- Inhibition of vitamin K epoxide reductase
- 5- Inhibition of vitamin K-dependent carboxylase

Answer & Comments

Answer: 4- Inhibition of vitamin K epoxide reductase

The Vitamin K epoxide is in turn recycled back to Vitamin K and Vitamin K hydroquinone by another enzyme, the vitamin K epoxide reductase (VKOR). Warfarin inhibits epoxide reductase (specifically the VKORC1 subunit), thereby diminishing available vitamin K and Vitamin K hydroquinone in the tissues, which inhibits the carboxylation activity of the glutamyl carboxylase. When this occurs, the coagulation factors are no longer carboxylated at certain glutamic acid residues, and are incapable of binding to the endothelial surface of blood vessels, and are thus biologically inactive

[Q: 900] OnExamination -
Haematology

A 24-year-old female student presented with fever and rigors for two days, fatigue, headache especially retro-orbital and diarrhoea.

In particular she complained of a weakness of the left side of her face and drooping of the lip. She had recently returned from a sabbatical in Uganda four weeks previously. She was febrile (39.9C), had a mild left facial nerve palsy, lymphadenopathy in her axillae and groin and she had an erythematous, maculopapular rash. Laboratory investigations showed.

Hb 12.0 g/dL (11.5-16.5)

WBC $3.0 \times 10^9/L$ (4-11)

Platelets $150 \times 10^9/L$ (150-400)

Blood film Lymphopaenia, some atypical lymphocytes seen

Which of the following is the most likely diagnosis?

- 1- Acute HIV infection (seroconversion illness)
- 2- Dengue fever
- 3- Infectious mononucleosis
- 4- Typhoid fever
- 5- Viral hepatitis

Answer & Comments

Answer: 1- Acute HIV infection (seroconversion illness)

Acute HIV seroconversion illness should be suspected where there has been a risk of exposure.

The symptoms and signs are often vague but the clinical presentation here is consistent. The median time from exposure to presentation is 25 days.

More than three quarters of patients who become infected with HIV develop symptoms consistent with primary HIV infection.

Symptoms typically appear a few days to a few weeks after exposure to HIV, and generally include several of the following:

- * Fever
- * Rash, often erythematous maculopapular
- * Fatigue
- * Pharyngitis
- * Generalized lymphadenopathy
- * Urticaria
- * Myalgia/arthralgia
- * Anorexia
- * Mucocutaneous ulceration
- * Headache, retroorbital pain
- * Neurologic symptoms (eg, aseptic meningitis, radiculitis, myelitis)

[Q: 901] OnExamination -
Haematology

An 80-year-old woman has a three month history of progressive numbness and unsteadiness of her gait. On examination, there is a mild spastic paraparesis, with brisk knee reflexes, ankle reflexes are present with reinforcement, extensor plantars, sensory loss in the legs with a sensory level at T10, impaired joint position sense in the toes, and loss of vibration sense below the iliac crests.

Investigations were as follows:-

haemoglobin 12.2 g/dl (12-16)

MCV 95 fl (85-95)

What is the most likely diagnosis?

- 1- anterior spinal artery occlusion
- 2- dorsal meningioma
- 3- multiple sclerosis
- 4- subacute combined degeneration of the cord
- 5- tabes dorsalis

Answer & Comments

Answer: 2- dorsal meningioma

The presence of a sensory loss at T10 indicates a thoracic myelopathy. Subacute combined degeneration of the cord is unlikely as Hb and MCV are normal. Anterior spinal artery occlusion is unlikely as the history is progressive.

[Q: 902] OnExamination -
Haematology

A 56-year-old female presents at the general practitioner with weakness. A full blood count reveals a haemoglobin concentration of 10.5 g/dl and an mean cell volume of 104 fl, but no other abnormality.

Which of the following may account for this?

- 1- Hormone replacement therapy
- 2- Thyrotoxicosis
- 3- Ulcerative colitis
- 4- Zollinger-Ellison syndrome
- 5- Scurvy

Answer & Comments

Answer: 5- Scurvy

Bear in mind this patient's symptoms and her FBC. She has weakness and in association with a mild anaemia (don't really think that this would cause the weakness) and her increased MCV a vitamin C deficiency is most probable. Vitamin C deficiency is associated with a macrocytosis and slight anaemia. HRT is more likely to be associated with Fe deficiency anaemia as is Zollinger-Ellison syndrome and ulcerative colitis. Hypothyroidism is associated with macrocytosis.

[Q: 903] OnExamination -
Haematology

A 75-year-old male is admitted with tiredness and lethargy and is found to have an enlarged

right supraclavicular mass.

Past medical history reveals that he had been developed acrocyanosis, six months previously and two months ago had been admitted with a chest infection for which he was treated with Co-Amoxiclav.

Investigations reveal:

blood film red cell auto-agglutination

direct antiglobulin test positive

cold agglutinin test positive

What is the most likely diagnosis?

- 1- Bronchial carcinoma
- 2- Drug-induced haemolysis
- 3- Mycoplasma pneumoniae infection
- 4- non-Hodgkin's lymphoma
- 5- Paroxysmal cold haemoglobinuria

Answer & Comments

Answer: 4- non-Hodgkin's lymphoma

Results are consistent with an Autoimmune Haemolytic screen caused by a Cold antibody. Drug induced haemolysis does not give these results. Bronchial Ca can give rise to an autoimmune haemolytic process but the antibody is usually warm- you do not get red cell agglutination or a positive cold agglutinin test.

PCH is a rare syndrome of acute intravascular haemolysis after exposure to cold caused by the Donath Landsteiner Antibody. Typically follows a viral illness or syphilis and usually self limiting.

The results and clinical description of acrocyanosis are consistent with a cold auto antibody.(Cold Autoimmune Haemolytic Anaemia)

The Antibody attaches to the RBC's in the peripheral circulation where the blood is cold, causing agglutination of the RBC's in the small vessels leading to the acrocyanosis. It is an

IgM Ab that can fix complement and cause both intra- and extravascular haemolysis. It can be a primary phenomenon (Idiopathic cold haemagglutinin disease) or secondary to infection eg. *Mycoplasma pneumoniae* or EBV or secondary to lymphoma.

The acrocyanosis developed before the chest infection, and in view of the lymphadenopathy, then NHL is the likely cause.

[Q: 904] OnExamination -
Haematology

Whilst being investigated for infertility, a 30-year-old woman is noted to have some bruising on her limbs with a palpable spleen on abdominal examination.

Investigations reveal:

Haemoglobin 10.0 g/dL (11.5 - 16.5)

White cell count $110 \times 10^9/L$ (4 - 11)

Neutrophils $60 \times 10^9/L$ (1.5 - 7)

Lymphocytes $2 \times 10^9/L$ (1.5 - 4)

Monocytes $0.8 \times 10^9/L$ (0 - 0.8)

Eosinophils $0.3 \times 10^9/L$ (0.04 - 0.4)

Basophils $0.7 \times 10^9/L$ (0 - 0.1)

Myelocytes $40 \times 10^9/L$

Myeloblasts $4 \times 10^9/L$

Platelet count $900 \times 10^9/L$ (150 - 400)

What is the most likely diagnosis?

- 1- Acute myeloid leukaemia
- 2- Acute promyelocytic leukaemia
- 3- Chronic myeloid leukaemia
- 4- Essential thrombocythaemia
- 5- Myelofibrosis

Answer & Comments

Answer: 3- Chronic myeloid leukaemia

The features of this blood film are anaemia, thrombocytosis, neutrophilia with roughly

55% neutrophils, 40% myelocytes with less than 5% blast cells. This is typical of Chronic Myeloid Leukaemia which usually has associated tender splenomegaly. Usually the Philadelphia chromosome is present in 95% of cases. Acute leukaemia is defined as blast cells constituting over 30% of cell type present. Chronic myeloid leukaemia often ends in acute blastic transformation after a mean duration of approx 4 years.

[Q: 905] OnExamination -
Haematology

Which of the following conditions is most likely to be associated with thrombocytopenia?

- 1- haemophilia A
- 2- hereditary haemorrhagic telangiectasia
- 3- pernicious anaemia
- 4- porphyria
- 5- uraemia

Answer & Comments

Answer: 3- pernicious anaemia

Pernicious anaemia is usually a megaloblastic anaemia but may also be associated with a pancytopenia.

The platelet count is usually normal in chronic renal failure but there is a platelet function abnormality.

[Q: 906] OnExamination -
Haematology

A 40-year-old man presents with bleeding gums and ease of bruising. His only medication is omeprazole for dyspepsia.

Investigations show:

Haemoglobin 12.5 g/dL (13.0-16.5)

MCV 90 fL (83-95)

Platelets $20 \times 10^9/L$ (150-400)

Blood film: occasional giant platelets

Prothrombin time 13.5s (11.5-15.5)

What is the most likely diagnosis?

- 1- Amegakaryocytic thrombocytopenia
- 2- Disseminated intravascular coagulation
- 3- Drug-induced thrombocytopenia
- 4- Immune thrombocytopenia
- 5- Thrombotic thrombocytopenic purpura

Answer & Comments

Answer: 4- Immune thrombocytopenia

Only abnormality is the very low platelet count. The Bone marrow is still working as there are giant platelets seen on film, which you see when there is peripheral consumption of the platelets(rules out A).

The large platelets are a sign that the bone marrow is churning them out prematurely to keep up with demand.

With disseminated intravascular coagulation the prothrombin time would be prolonged.

With thrombotic thrombocytopenic purpura the haemoglobin would be low- as haemolysis is a feature.

Drug-induced thrombocytopenia in itself is an immune mechanism, and while Lansoprazole can cause a reduction in platelet count, it is not classically a drug you associate with drug induced thrombocytopenia.

Immune thrombocytopenia, is very common, and would give this very low platelet count, and by choosing this answer it covers drug induced thrombocytopenia as well.

[Q: 907] OnExamination - Haematology

An eighty-year-old man presents with tiredness and weakness. A diagnosis of myelodysplastic syndrome is suspected.

Which of the following statements regarding myelodysplastic syndrome is correct?

- 1- Absence of ring sideroblasts on the blood film excludes myelodysplasia as a diagnosis
- 2- Cytotoxic chemotherapy is likely to be part of his treatment
- 3- He is more likely to die from an infection than from leukaemic transformation
- 4- If blast cells constitute 1% of the total white cells, this signifies leukaemic transformation.
- 5- On a blood film, neutrophils typically show toxic granulation

Answer & Comments

Answer: 3- He is more likely to die from an infection than from leukaemic transformation

The patient has myelodysplastic syndrome (MDS). Myelodysplastic syndrome is a disease of old age. Men are affected more frequently than women. 80% of patients present because of symptoms of anaemia. The blood film typically shows pancytopenia with hypogranular neutrophils. The number of blasts seen varies.

The disease can be classified into five subtypes:

- " 1. Refractory anaemia (<5% blasts)
- " 2. Refractory anaemia with ring sideroblasts (<5% blasts; >15% sideroblasts)
- " 3. Refractory anaemia with excess blasts (5-19% blasts)
- " 4. Refractory ansema with excess blasts in transformation (blasts 20-29% - near AML)
- " 5. CML (> 1 x 10⁹/L monocytes)

Few patients require aggressive therapy and most need only supportive care. As the vast majority are elderly patients with other medical conditions, excessive intervention is unwarranted. Transfusions of packed red cells or platelets may be required and antibiotics for intercurrent infections. G-CSF and r-Epo

can improve blood counts. Aggressive cytotoxic chemotherapy is generally reserved for treatment of transformation to AML in younger patients.

Median survival is two years. Patients are more likely to have serious infections or life-threatening bleeds than blastic transformation.

[Q: 908] OnExamination -
Haematology

Which of the following is a proto-oncogene?

- 1- The N-Myc gene
- 2- The WT1 (first Wilm's tumour) gene
- 3- The Retinoblastoma gene
- 4- The WT2 (second Wilm's tumour) gene
- 5- The BCRab1 translocation (Philadelphia chromosome)

Answer & Comments

Answer: 1- The N-Myc gene

Oncogenes are endogenous human DNA sequences that arise from normal genes called proto-oncogenes. Proto-oncogenes are normally expressed in many cells, particularly during fetal development, and are thought to play an important regulatory role in cell growth and development. Alterations in the proto-oncogene can activate an oncogene, which produces unregulated gene activity, contributing directly to tumourigenesis. Oncogene alterations are important causes of:

- " Rhabdomyosarcomas (ras oncogene).
- " Burkitt's lymphoma (C-myc is translocated intact from its normal position on chromosome 8 to chromosome 14).
- " Neuroblastoma (N-myc proto-oncogene is seen in a proportion of patients with poor prognosis).

They should be contrasted with tumour suppressor genes. In this situation, the genes

normally down regulate cell growth, and require inactivation to allow malignant growth. Examples include retinoblastoma.

[Q: 909] OnExamination -
Haematology

Which of the following haematological disorders is inherited as an autosomal recessive condition?

- 1- Antithrombin III deficiency
- 2- Protein C deficiency
- 3- Glucose-6-phosphate dehydrogenase deficiency
- 4- Pyruvate kinase deficiency
- 5- Acute intermittent porphyria

Answer & Comments

Answer: 4- Pyruvate kinase deficiency

Anti-thrombin 3 (AT3) is a plasma inhibitor protein that blocks the enzymatic activity of some serine proteases coagulation factors. The activity of this inhibitor is increased by heparin. AT3 is synthesised by the liver, is not Vitamin K dependent, and can be consumed during DIC. Normal newborns have a reduced activity. Congenital AT3 deficiency is an autosomal dominant. Treatment of thrombotic in these events in these patients may be difficult.

Protein C is an inhibitor that once activated inhibits clot formation and enhances fibrinolysis. It is liver synthesised and Vitamin K dependent. Protein C is converted to an active enzyme by a thrombin-thrombomodulin complex on the endothelial cell surface. Activated protein C inhibits a plasminogen activator inhibitor, which results in enhanced fibrinolysis, and, with protein S as a co-factor, inhibits the clotting of the activated factors 5 and 8 by limited proteolysis. Activated protein C thus controls the conversion of factor 10 to 10a and prothrombin to thrombin. Congenital

deficiency is an autosomal dominant trait. Acquired deficiency may occur in association with infection.

Glucose-6-phosphate dehydrogenase deficiency is the most important disease of the pentose phosphate pathway, and is responsible 2 clinical syndromes: an episodic haemolytic anaemia induced by infections or certain drugs, and a spontaneous chronic non-spherocytic haemolytic anaemia. The deficiency is X-linked, and heterozygous females are resistant to falciparum infections. There are a large number of abnormal alleles causing disease of vastly different severity.

Pyruvate kinase deficiency is a rare congenital haemolytic anaemia inherited as an autosomal recessive. Generation of ATP within the red cell is impaired resulting in an abnormally high concentration of 2,3,DPG in the red cell, which inhibits the enzymes of the pentose phosphate pathway. Clinical manifestations vary from severe neonatal haemolysis, to a mild well compensated haemolysis first noted in adulthood.

Acute intermittent porphyria is an autosomal dominant disorder resulting from partial porphobilinogen deaminase deficiency in the cytosol of all tissues including erythrocytes. Clinical expression of the disease is linked to environmental or acquired factors such as nutritional status, drugs, steroid or chemicals. The major abnormality is of the peripheral, autonomic or CNS. Major symptoms are abdominal pain, nausea, vomiting, constipation or diarrhoea. In severe cases the urine develops a port wine colour due to the high content of porphobilin, an auto-oxidation product of PBG. Hypertension and neuropathy are common, with muscle weakness, cranial nerve abnormality and seizures.

[Q: 910] OnExamination - Haematology

A patient presents with acute promyelocytic leukaemia.

What is the likely mechanism underlying leukaemogenesis?

- 1- aberrant fusion of 2 genes
- 2- impaired protein degradation
- 3- over expression of cellular oncogene
- 4- post-translational modification
- 5- telomere shortening

Answer & Comments

Answer: 1- aberrant fusion of 2 genes

In APL, one of the Retinoic Acid Receptor genes, RARA, is fused to PML in the great majority of patients as a result of the chromosomal translocation t(15; 17).

[Q: 911] OnExamination - Haematology

A patient who received total body irradiation for the treatment of Hodgkin's Lymphoma develops Graft Versus Host Disease (GVHD).

Which of the following blood products is likely to have caused this?

- 1- Cryoprecipitate
- 2- FFP
- 3- Frozen deglycerolized red blood cells
- 4- Immunoglobulin
- 5- Packed red blood cells

Answer & Comments

Answer: 5- Packed red blood cells

Graft versus host disease (GVHD) occurs when donor lymphocytes engraft in a susceptible recipient. Products implicated in cases of TA-GVHD include non-irradiated whole blood, packed red blood cells, platelets, granulocytes and fresh non-frozen plasma. Frozen deglycerolized red blood cells, fresh frozen plasma and cryoprecipitate have not been implicated.

[Q: 912] OnExamination -
Haematology

A 17-year-old girl with mild Von Willebrand's disease is scheduled for dental extraction. A previous dental extraction resulted in bleeding that had required two unit transfusion.

What is the most appropriate treatment prior to dental surgery?

- 1- Cryoprecipitate
- 2- DDAVP
- 3- Fresh frozen plasma
- 4- High purity factor VIII concentrate
- 5- Recombinant factor VIII concentrate

Answer & Comments

Answer: 2- DDAVP

DDAVP is the choice treatment for mild vonWillebrand disease, which would include Type I, and the majority of Type II, although there is some controversy in Type II B as it is thought that DDAVP can exacerbate thrombocytopenia that can accompany this type of Von Willebrand's.

It is of no use in Type III - severe Von Villebrand's disease. The history tells us that she has mild disease.

You would not use cryoprecipitate or Fresh frozen plasma in these patients in this era due to potential viral transmission risk from blood products. For severe disease you would use a Von Willebrand factor concentrate, not factor VIII concentrate.

[Q: 913] OnExamination -
Haematology

A 70-year-old male is diagnosed with multiple myeloma and is treated with melphalan and prednisolone.

Which of the following when added to this chemotherapeutic regime would be expected to improve survival?

- 1- Cyclosporin
- 2- Interferon alpha
- 3- Methotrexate
- 4- Thalidomide
- 5- Simvastatin

Answer & Comments

Answer: 4- Thalidomide

Significant improvements in survival may be expected through the addition of Thalidomide to standard chemotherapeutic regimes. Studies suggest a significant improvement at both 2 years and 5 years with Thalidomide.

[Q: 914] OnExamination -
Haematology

A 71-year-old man presents with a tender left calf and has a background history of headaches, tiredness and dizziness. He is a smoker of 20 cigarettes daily and drinks 45 units of alcohol weekly. On examination he was plethoric, had a blood pressure of 186/102 mmHg and has a swollen, hot tender and erythematous left calf. Dopplers confirm the presence of a deep vein thrombosis.

Investigations reveal:

haemoglobin 19 g/dL (13-18)

haematocrit 0.58 (0.4-0.52)

white cell count $12.5 \times 10^9/L$ (4-11)

platelet count $500 \times 10^9/L$ (150-400)

Which one of the following is the most appropriate investigation to establish the diagnosis?

- 1- Abdominal ultrasound scan
- 2- Arterial blood gases
- 3- Red blood cell mass
- 4- Bone marrow trephine
- 5- Leucocyte alkaline phosphatase score

Answer & Comments

Answer: 3- Red blood cell mass

The most significant abnormality is the raised Haemoglobin and Haematocrit suggesting polycythaemia which in the presence of all the other features suggest secondary polycythaemia. Therefore, the most useful INITIAL investigation will be red cell mass studies which would distinguish between true and relative polycythaemia- further investigations will then be dictated by the results of this initial test- an USS, bone marrow etc and blood gases may be needed after the initial red cell mass studies. The leucocyte alkaline phosphatase score is rather outdated and seldom performed.

The raised WCC and platelet count would suggest that this is primary polycythaemia not apparent polycythaemia but red blood cell mass is still the best answer.

[Q: 915] OnExamination - Haematology

A 62-year-old male is diagnosed with Chronic myeloid leukaemia and his investigations show that both Philadelphia chromosome and bcr/abl gene is present.

What is the significance of the presence of the bcr/abl gene?

- 1- Acts on stem cell line DNA
- 2- Blocks apoptosis
- 3- Codes for the production of a tyrosine kinase in the leukaemic cells
- 4- Increases production of granulocyte colony stimulating factor
- 5- Increases expression of granulocyte colony stimulating factor receptors on the cell membrane.

Answer & Comments

Answer: 3- Codes for the production of a tyrosine kinase in the leukaemic cells

The product of the bcr/abl gene that is seen 97% cases of Chronic Myeloid Leukaemia, is a constitutively active Tyrosine Kinase, this is responsible for the leukaemic process.

[Q: 916] OnExamination - Haematology

A 22-year-old male presents with episodic nausea and abdominal pain although has maintained a normal weight. The symptoms have been attributed to irritable bowel syndrome. There are no abnormalities on examination. Blood tests were performed which reveal:

Haemoglobin 12.2 g/dl (11.5-16)

MCV 92fl (83-95)

White cell count $6.5 \times 10^9/L$ (4-10)

Platelets $310 \times 10^9/L$ (150-400)

Reticulocytes 5%

Bilirubin 42 micromol/l (0-18)

AST/ALP Normal

Coomb's test negative

Haptoglobin undetectable

Which of the following is the likely diagnosis?

- 1- Acute intermittent porphyria
- 2- Dubin-Johnson syndrome
- 3- Gilbert's syndrome
- 4- Hereditary spherocytosis
- 5- Viral hepatitis

Answer & Comments

Answer: 4- Hereditary spherocytosis

This patient has an elevated bilirubin concentration and elevated reticulocyte count suggesting haemolysis. The most likely explanation would be hereditary spherocytosis which could be confirmed on blood film. This too explains the symptoms - nausea and abdominal pains suggesting gallstones, which is common even in mild disease.

[Q: 917] OnExamination -
Haematology

Which of the following statements regarding lymphomas in childhood is correct?

- 1- Hodgkin's disease is more common than non-Hodgkin's under the age of 5 years.
- 2- Hodgkin's disease has equal sex incidence.
- 3- lymphocyte-predominant Hodgkin's disease has the worse prognosis.
- 4- the nodular sclerosing variety is the most common form of Hodgkin's disease.
- 5- the most common presenting clinical sign is splenomegaly.

Answer & Comments

Answer: 4- the nodular sclerosing variety is the most common form of Hodgkin's disease.

Hodgkin's lymphoma occurs in four forms: (1) lymphocyte-predominant (10-20%) with the best prognosis; (2) nodular sclerosing (50%) which is the most common form; (3) mixed cellularity (40-50%) which is most likely to have extranodal disease at presentation; and (4) lymphocyte depleted (<10%) which is the rarest type with the worst prognosis. Hodgkin's disease is rarely found in children aged less than 5 years old (male:female ratio=2:1) and peaks at between 15 and 34 years. Non-Hodgkin's disease is more common in younger children (male:female ratio=3:1). The most common presenting clinical sign is enlarged cervical lymph nodes. From Hannam et al. MRCP (Paediatrics) Part 1 MCQs. page 15 ?WB Saunders. Reproduced with permission.

[Q: 918] OnExamination -
Haematology

A patient with AML develops jaundice and spiking pyrexia 3 weeks into induction chemotherapy. The patient remained pyrexial after 7 days of intravenous antibiotics.

What is the likely diagnosis?

- 1- CMV
- 2- Fungal infection
- 3- Hepatic leukaemic deposits
- 4- Miliary TB
- 5- Toxoplasmosis

Answer & Comments

Answer: 1- CMV

The most likely cause for the persisting pyrexia plus hepatitis in this immunocompromised patient treated with appropriate antibiotics would be a CMV infection. Fungal infection would not be expected to cause the jaundice but again may be responsible for the pyrexia. TB would be most unlikely and hepatic infiltration would not be expected to produce this pyrexia.

[Q: 919] OnExamination -
Haematology

Which of the following statements regarding thrombocytosis is correct?

- 1- The commonest cause is Essential Thrombocythaemia
- 2- Occurs exclusively in essential thrombocythaemia
- 3- Erythropoietin is the key hormone in the regulation of megakaryocyte differentiation
- 4- May occur as a response to exercise
- 5- Secondary thrombocytosis is an indication for hydroxycarbamide therapy

Answer & Comments

Answer: 4- May occur as a response to exercise

The commonest cause of thrombocytosis is a reactive thrombocytosis. Thrombocythaemia may occur in any of the myeloproliferative disorders, particularly PRV. Thrombopoietin is the key hormone in the regulation of

megakaryocyte differentiation. Secondary thrombocytosis does not place the patient at risk for haemostatic nor cardiovascular events.

[Q: 920] OnExamination -
Haematology

Which of the following statements concerning abnormalities of the haemoglobin molecule is true?

- 1- Alpha thalassaemia is due to a deficiency of beta-chain production
- 2- HbS is caused by a single base mutation on the beta-chain
- 3- genes for the alpha and beta chains are located on the same chromosome
- 4- in thalassaemia persistence of HbF is an adverse prognostic sign
- 5- oligonucleotide probes may assist in the diagnosis of haemoglobinopathies in adolescents

Answer & Comments

Answer: 2- HbS is caused by a single base mutation on the beta-chain

Alpha Thalassaemia is due to abnormalities of the alpha chain. Persistence of HbF has survival advantages in severely affected subjects. C-alpha 16, beta 11. e-Hb electrophoresis in the adult rather than oligonucleotide probes as used in the fetus (Dr Shu Ho)

[Q: 921] OnExamination -
Haematology

Heinz bodies in red blood cells in haemolytic anaemia is present in

- 1- paroxysmal nocturnal haemoglobinuria
- 2- Glucose 6 phosphate dehydrogenase deficiency
- 3- post splenectomy
- 4- cold agglutinin disease

- 5- clostridium welchii septicaemia

Answer & Comments

Answer: 2- Glucose 6 phosphate dehydrogenase deficiency

Heinz bodies = oxidised denatured Hb. Post splenectomy causes target cells, Pappenheimer bodies (siderotic granules) and Howell-Jolly bodies (DNA remnants).

[Q: 922] OnExamination -
Haematology

A 45-year-old Chinese man is found incidentally to have a severely hypochromic and microcytic blood picture, with Hb 11.2g/dl. He is asymptomatic.

Which of the following is the most discriminatory investigation?

- 1- Barium enema
- 2- Gastroscopy
- 3- Haemoglobin electrophoresis
- 4- Bone marrow biopsy
- 5- Ham test

Answer & Comments

Answer: 3- Haemoglobin electrophoresis

Thalassaemia trait is a common, usually asymptomatic abnormality. Red cells are hypochromic and microcytic, but iron and ferritin stores are normal. Haemoglobin electrophoresis shows raised HbA₂ (>3.5%) and raised HbF (normally consist predominantly of HbA with trace of HbF and HbA₂).

[Q: 923] OnExamination -
Haematology

A 42-year-old man presented with tiredness, breathlessness, and nose bleeds for three weeks. On examination there were several bruises on his arms and legs, 2 cm

splenomegaly and fundal haemorrhages.
Investigations revealed:

haemoglobin 7.2 g/dL (11.5-16.5)

white cell count $13.8 \times 10^9/L$ (4-11)

platelet count $24 \times 10^9/L$ (150-400)

blood film white cells predominantly myeloblasts and promyelocytes

Which one of the following investigations would be of most prognostic value?

- 1- cerebrospinal fluid examination
- 2- cytochemistry
- 3- cytogenic karyotype
- 4- immunophenotyping
- 5- bone marrow trephine biopsy

Answer & Comments

Answer: 3- cytogenic karyotype

Cytogenetic evaluation of malignant haematological cells may have important implications for the prognosis and treatment options in AML. For example t(8;21) confers a good prognosis in adult AML, and about 70% of patients in this low-risk group can be cured with intensive chemotherapy alone, radiotherapy being reserved for patients who relapse.

[Q: 924] OnExamination -
Haematology

A 30-year-old male presents with episodic jaundice and anaemia and has been diagnosed with glucose-6-phosphate dehydrogenase (G6PD) deficiency.

On further testing, his wife has normal plasma G6PD activity.

What is the risk of their children developing this condition?.

Which one of the following statements is correct?

- 1- 50% of their children will be affected, irrespective of gender
- 2- All their sons will be affected
- 3- All their children will be affected
- 4- All their daughters will be affected
- 5- None of their children will be affected

Answer & Comments

Answer: 5- None of their children will be affected

G6PD is X linked- therefore females are carriers, and are not usually affected, unless there is inactivation of their X chromosome, Males are affected.

Males will pass on the 'bad' X chromosome to their daughters so that they become carriers, and are said above they are not usually affected. Males pass on their Y chromosomes to any sons, therefore they will not be affected.

In the question the male is affected, but as the female has normal levels of the enzyme, we are assuming she is not a carrier (although strictly she could be a carrier and have normal levels).

The male will pass on the X chromosome to any daughters, who will not be affected, as they will have a 'good' X from the mothers, and the father will pass on the Y chromosome to his sons, which will not be affected.

[Q: 925] OnExamination -
Haematology

Folic acid metabolism can be affected by

- 1- tetracycline
- 2- pyrimethamine
- 3- Vitamin B₁₂
- 4- penicillin
- 5- brufen

Answer & Comments

Answer: 2- pyrimethamine

Drugs which inhibit dihydrofolate reductase = methotrexate, pyrimethamine and trimethoprim. Drugs which interfere with absorption/storage of folate = phenytoin, primidone, oral contraceptives.

[Q: 926] OnExamination - Haematology

A 50-year-old female presents with acute chest pain and dyspnoea.

Examination reveals bilateral ankle oedema with 24 hr urine protein assessment showing 8g/d (<0.2).

Which is the most likely explanation for these findings?

- 1- factor V Leiden
- 2- reduced antithrombin III activity
- 3- reduced concentration of Von Willebrand's factor
- 4- reduced fibrinogen concentration
- 5- reduced factor VIII

Answer & Comments

Answer: 2- reduced antithrombin III activity

This patient has developed nephrotic syndrome. and appears to have had a thromboembolic event. The suggestion is that she has had nephritic syndrome before developing the thromboembolism. Deranged coagulation associated with Nephrotic syndrome is a consequence of AT III deficiency, increased fibrinogen and increased Factor VIIIc.

[Q: 927] OnExamination - Haematology

A 61-year-old, who has smoked for 40 years, presents with thoracic back pain.

His investigations reveal:

Haemoglobin 11.1 g/dl

Urea 9.3 mmol/l

Creatinine 298 micromol/l

Calcium 3.67 mmol/l

Albumin 30 g/l

Total protein 97 g/l

Thoracic spine X-ray collapse of T8

Which investigation would confirm the diagnosis?

- 1- Bone Marrow Aspirate
- 2- CXR
- 3- Creatinine Clearance
- 4- ESR
- 5- PTH

Answer & Comments

Answer: 1- Bone Marrow Aspirate

This man has myeloma. The smoking is a red herring. Myeloma typically presents with back pain often associated with pathological fractures. He is mildly anaemic, there is renal impairment and hypercalcaemia, with a raised total protein secondary to a paraproteinaemia. Bone marrow examination would reveal increased plasma cells (>4% and usually >30%). The ESR will be raised, but the bone marrow aspirate would confirm the diagnosis irrefutably.

[Q: 928] OnExamination - Haematology

A 21-year-old man with non-Hodgkin's lymphoma and haemolytic anaemia is assessed for splenectomy.

When should Pneumovax vaccine be administered?

- 1- one month before surgery
- 2- one week before surgery
- 3- one week after surgery

- 4- one month after surgery
5- perioperatively

Answer & Comments

Answer: 1- one month before surgery

The vaccine should be given a minimum of two weeks before elective splenectomy in order to ensure an optimal antibody response. In emergency splenectomy the patient should be immunized as soon as possible after recovery from the operation and before discharge from hospital. Unvaccinated patients splenectomized some time earlier should be vaccinated at the first opportunity. Vaccination is delayed for at least six months after immunosuppressive chemotherapy or radiotherapy, during which time prophylactic antibiotics should be given.

[Q: 929] OnExamination -
Haematology

A 32-year-old man was prescribed an oral antibiotic for a urinary tract infection. Two days later he noticed that his urine was increasingly dark in colour. Investigations revealed:

haemoglobin 8.5g/dL (13.0-18.0)

reticulocytes $147 \times 10^9/L$ (25-85)

Blood film: marked anisopoikilocytosis and bite cells

What is the most likely diagnosis?

- 1- Acute Myeloid Leukaemia
- 2- Autoimmune haemolytic anaemia
- 3- haemoglobin H disease
- 4- hereditary spherocytosis
- 5- paroxysmal cold haemoglobinuria

Answer & Comments

Answer: 2- Autoimmune haemolytic anaemia

I think that this is a difficult question!

Paroxysmal cold hemoglobinuria (PCH) is a rare type of autoimmune hemolytic anemia (AIHA), occurring primarily in children. The classic symptom of PCH is a sudden onset of hemoglobinuria following exposure to cold, even for a few minutes. Symptoms may occur minutes to hours following exposure to cold. Hemoglobinuria is not always present because, in some persons with PCH, the autoantibody level is not high enough to cause intravascular hemolysis. PCH is usually of abrupt onset in the setting of an infectious disease. Given the patient's age, and the specific history in this case, the diagnosis is unlikely to be PCH. If the diagnosis was hereditary spherocytosis, then the blood film would show spherocytes. In Haemoglobin H disease, the typical inclusions can be demonstrated in erythrocytes stained with brilliant cresyl blue, and a chronic microcytic, hypochromic anaemia would be present. Haemolytic anaemia may be precipitated by sulfonamides, and also by penicillins. This gentleman may have been treated with trimethoprim or a penicillin, which then caused AIHA, with the typical blood film. I feel that the most appropriate answer to this question is B, given the patient's age, the lack of history of exposure to cold, and the history which is given of antibiotic prescription.

[Q: 930] OnExamination -
Haematology

Which of the following public health measures would reduce the incidence of iron deficiency anaemia?

- 1- Using doorstep cow's milk from 6 months of age.
- 2- Giving young children tea rather than fruit juice.
- 3- Delaying the introduction of mixed feeding until 9 months of age.
- 4- Giving 0.5mg per day of elemental iron to all preterm babies.

5- Continuing breast feeding until a year of age.

Answer & Comments

Answer: 5- Continuing breast feeding until a year of age.

Answer: 5) Continuing breast feeding until a year of age

The following would achieve primary prevention of iron deficiency anaemia:

" Provision of adequate iron supplements for premature and low birth weight infants in adequate dosage (2mg/kg of elemental iron per day).

" Not using unmodified doorstep milk in the first year of life. Although breast milk has a low iron concentration, the relative bioavailability is much higher than from modified or unmodified cow's milk.

" Not giving young children tea (this reduced iron's bioavailability).

" Use of follow-on or ordinary infant formulae in the second half of the first year of life.

" Weaning on to mixed feeding by 6 months of age.

" Iron supplementation for all children in high risk groups.

[Q: 931] OnExamination -
Haematology

A 70-year-old female presents with a three month history of exertional dyspnoea and chest pain. She admitted to a poor diet, some vague abdominal pains and having lost 7kg in weight.

Examination revealed pallor, patches of vitiligo on her arms and trunk, ankle oedema and a palpable spleen.

Investigations revealed:

Haemoglobin 5 g/dl (11.5-16.5)

MCV 105 fL (80-96)

White cell count $2 \times 10^9/L$ (4-11)

Platelet count $50 \times 10^9/L$ (150-400)

Bilirubin 40 $\mu\text{mol/L}$ (1-22)

ALT 60 U/L (5-35)

AST 40 U/L (1-31)

LDH 1000 U/L (10-250)

Which one of the following is the most likely diagnosis?

1- Aplastic anaemia

2- Autoimmune haemolytic anaemia

3- Dietary folate deficiency

4- Pernicious anaemia

5- Sideroblastic anaemia

Answer & Comments

Answer: 4- Pernicious anaemia

There is pancytopenia, with anaemia being more significant. The anaemia is macrocytic. LDH is very high with some derangement of LFT's. Aplastic anaemia would cause pancytopenia but not a raised LDH.

Autoimmune haemolysis and Sideroblastic anaemia would not cause pancytopenia.

Folate deficiency and Pernicious Anaemia would both cause the above results- the LDH is elevated due to ineffective erythropoiesis and likewise the deranged LFT's.

Pernicious Anaemia is more likely given the history of other autoimmune disease.

Of note, with such a low Haemoglobin one would expect a much higher MCV; but sometimes when the deficiency is severe, the red cell anisopoikilocytosis causes a lower MCV.

[Q: 932] OnExamination -
Haematology

A 23-year-old footballer was prescribed Ibuprofen by his GP for a sprained ankle. Several hours later he felt very unwell and was passing dark urine. The peripheral blood film shows many schistocytes. The lab results show:

Haemoglobin <9 g/L

WBC 7×10^9 /L with normal differentials

Platelets 450×10^9 /L

Reticulocyte count 5%

Bilirubin 40 μ mol/L

What is the most likely cause for her presentation?

- 1- Allergic reaction
- 2- Autoimmune haemolytic anaemia
- 3- Glucose-6-phosphate dehydrogenase deficiency
- 4- Paroxysmal nocturnal haemoglobinuria
- 5- Pyruvate kinase deficiency

Answer & Comments

Answer: 3- Glucose-6-phosphate dehydrogenase deficiency

This is a case of intravascular haemolysis with haemoglobinuria. The patient has the history of taking Ibuprofen which is an oxidant and causes hemolysis in patients with G-6-PD deficiency. Oxidative stressors can be infectious agents, drugs, chemicals and certain legumes. In G-6-PD deficient patients, oxidative stress exposes interior sulphhydryl groups that are oxidized and cannot be reduced, leading to irreversible denaturation of the hemoglobin with Heinz body formation. Schistocytes are red blood cell fragments that result from membrane damage. They are sometimes referred to as "bite cells".

[Q: 933] OnExamination -
Haematology

Which of the following statements regarding Disseminated intravascular coagulation is most correct?

- 1- Removal of the underlying cause of the DIC will lead to resolution the manifestations of DIC
- 2- DIC is associated with a rising platelet count
- 3- DIC is associated with rising fibrinogen levels
- 4- Normal clotting parameters effectively excludes a diagnosis of DIC
- 5- DIC is associated with an elevated D-Dimer

Answer & Comments

Answer: 5- DIC is associated with an elevated D-Dimer

DIC is caused by the enhanced and abnormally sustained generation of thrombin, and is associated with elevated products of fibrin breakdown, one of these being D-Dimer. Treatment of the underlying cause eg sepsis, does not always lead to resolution of the condition, and recombinant human activated protein C has been shown to be effective in reducing mortality from DIC in patients with sepsis. DIC is associated with a falling platelet count, decreased fibrinogen, but the clotting factors may be normal, especially when one considers that the acute phase response may shorten the APTT and increase fibrinogen. For an excellent review see BMJ 2003;327:974-7.

[Q: 934] OnExamination -
Haematology

A 30-year-old female presents to the antenatal clinic with her first pregnancy. During the interview she reports that she has been entirely well but her sister had had a deep vein thrombosis in her second pregnancy. A thrombophilia screen shows that she is heterozygous for factor V Leiden.

Which is the most appropriate action for this patient?

- 1- She should be informed to seek medical attention if she becomes aware of calf swelling or pain
- 2- She should be treated with Aspirin 75mg daily
- 3- She should be treated with prophylactic low molecular weight Heparin
- 4- She should be treated with prophylactic unfractionated Heparin
- 5- She should receive Warfarin

Answer & Comments

Answer: 1- She should be informed to seek medical attention if she becomes aware of calf swelling or pain

Although she is heterozygous for Factor V Leiden, she has not had a previous thrombotic event.

There is no need to anticoagulate her throughout pregnancy. However she is at increased risk- pregnant and FVL- and should be very alert to the symptoms and signs of a thrombotic event. There is no evidence of benefit from aspirin to reduce her thrombotic risk.

[Q: 935] OnExamination - Haematology

In sickle cell disease:

- 1- The Sickledex test involves adding a reagent to blood, which allows the nature of the haemoglobinopathy to be determined
- 2- It is caused by the substitution of glutamic acid by valine at position 4 on the beta chain of haemoglobin
- 3- The erythrocytes of Haemoglobin AS patients can sickle at a pO_2 of 5 to 6 kPa (40-50 mmHg)

- 4- The erythrocytes of Haemoglobin SC patients may sickle at a pO_2 of 4 kPa (30 mmHg)
- 5- Exchange transfusions prior to major surgery on HbSS patients, aims to lower the HbS concentration to 60%

Answer & Comments

Answer: 4- The erythrocytes of Haemoglobin SC patients may sickle at a PO_2 of 4 kPa (30 mmHg)

Sickle cell disease is a haemoglobinopathy caused by the substitution of glutamic acid by valine at position 6 (from the N-terminal) of the beta chain. Inherited as an autosomal gene, heterozygous (HbAS) and homozygous (HbSS) forms exist. A low partial pressure of oxygen (PO_2) causes HbS to polymerise and precipitate, resulting in sickling of the erythrocyte. HbSS patients sickle at PO_2 of 5 ? 6 kPa and HbAS patients sickle at PO_2 of 2.5 - 4 kPa. A mild disease is produced when heterozygotes for HbS combine with other haemoglobins e.g. Haemoglobin C, thus creating HbSC. Sickling occurs at around 4 kPa. Diagnosis of sickle cell disease requires the detection of HbS. The Sickledex test involves the addition of reagent to blood; turbidity confirming the presence of HbS, but it gives no information on other haemoglobins. Haemoglobin electrophoresis is the only investigation that determines the nature of the haemoglobinopathy.

[Q: 936] OnExamination - Haematology

What is the mechanism of action of low-molecular-weight heparin?

- 1- Activation of plasminogen
- 2- Chelation of calcium
- 3- Inhibition of activated factor X
- 4- Inhibition of antithrombin

5- Inhibition of vitamin K-dependent carboxylase

Answer & Comments

Answer: 3- Inhibition of activated factor X

The shorter-chain low-molecular-weight (LMW) fractions of heparin inhibit activated factor X but have less effect on thrombin (and on coagulation in general) than the HMW species.

[Q: 937] OnExamination - Haematology

A 12-year-old boy was diagnosed with Haemophilia A. His uncle from the mother's side also has the same condition although his mother is well. The parents of the boy are worried about their next child suffering with the same condition.

What is the chance of the next child having the disease?

- 1- 0%
- 2- 25%
- 3- 50%
- 4- 75%
- 5- 100%

Answer & Comments

Answer: 2- 25%

Haemophilia is an X linked recessive disease. The mother is the carrier of the disease. There will be 50% chance in her sons to have the disease and all of her daughters will be carriers. However, it is not mentioned about the sex of the next child in this question. The overall chance of the next child to have the disease will be 25% and phenotypically normal child will be 75%.

[Q: 938] OnExamination - Haematology

A 73-year-old man presented with a two week history of breathlessness and easy bruising.

Investigations show:

Haemoglobin 6.9 g/dL (13.0-18.0)

White cell count $0.4 \times 10^9/L$ (4-11)

Platelet count $9 \times 10^9/L$ (150-400)

Bone marrow aspirate all cellular elements reduced

Which drug is the most likely cause of these abnormalities?

- 1- Acyclovir
- 2- Amiloride
- 3- Amoxicillin
- 4- Paracetamol
- 5- Trimethoprim

Answer & Comments

Answer: 5- Trimethoprim

There is a pancytopenia and marrow aspirate shows reduction in production of all cellular elements. Trimethoprim is the drug most likely of these 5 to cause depression of haematopoiesis as this picture would be particularly unusual with paracetamol, amiloride acyclovir and amoxicillin.

[Q: 939] OnExamination - Haematology

A 75-year-old woman receives 2 units of packed red cells following a hip replacement. One week later her haemoglobin concentration had fallen by 4 g/l.

Which one of the following would be most likely to indicate a delayed transfusion reaction?

- 1- conjugated hyperbilirubinaemia
- 2- elevated D-dimer concentration

- 3- haemoglobinuria
- 4- haemosiderinuria
- 5- positive direct antiglobulin test

Answer & Comments

Answer: 5- positive direct antiglobulin test

The features suggest immune haemolysis with DAT being diagnostic. A is inappropriate as it is unconjugated bilirubin that is raised in haemolysis. B,C and D are not going to be diagnostic of an immune haemolytic transfusion reaction.

[Q: 940] OnExamination - Haematology

A 69-year-old male presents with tiredness and dyspnoea and is diagnosed with acute myeloid leukaemia.

Which of the following is the most important prognostic factor?

- 1- Elevated lactate dehydrogenase activity
- 2- Karyotype of bone marrow
- 3- Monocytic morphology
- 4- Number of blasts in bone marrow
- 5- White cell count at diagnosis

Answer & Comments

Answer: 2- Karyotype of bone marrow

A, C, and D have no prognostic value. White cell count at diagnosis is however important, but most important is the karyotype of bone marrow, as this result stratifies patients into lower risk, standard risk and poor risk, which has prognostic significance.

[Q: 941] OnExamination - Haematology

A 56-year-old male was admitted for a total hip replacement due to osteoarthritis. There was no other medical history and physical

examination was normal. A routine pre-operative FBC showed:

Haemoglobin 11 g/dl (11.5-16.5)
 Platelet count $170 \times 10^9/L$ (150-400)
 White cell count $25 \times 10^9/L$ (4-11)
 Neutrophil count $5 \times 10^9/L$ (1.5-7)
 Lymphocyte count $19 \times 10^9/L$ (1.5-4)
 Monocyte count $0.9 \times 10^9/L$ (0-0.8)
 Eosinophil count $0.1 \times 10^9/L$ (0.04-4)
 Basophil count $0.08 \times 10^9/L$ (0-0.1)
 His Blood film shows mature lymphocytes

What is the most appropriate initial management for this patient?

- 1- Cancel the patient's operation
- 2- Chlorambucil
- 3- Fludarabine
- 4- Observation
- 5- Prednisolone

Answer & Comments

Answer: 4- Observation

The most significant abnormality on the full blood count is the lymphocytosis, with mature lymphocytes seen on film. In this age group the most likely diagnosis is a low grade lymphoproliferative disorder e.g. Chronic Lymphocytic Leukaemia. This, as mentioned, is a low grade condition, and does not require immediate treatment; patients undergo a period of observation, often quite long, before any treatment is indicated.

The indication for treatment would include:

- 1. Disabling B symptoms
- 2. Lymphocyte doubling time of < 6 months
- 3. Bone Marrow compromise
- 4. Autoimmune haemolysis or immune thrombocytopenia.

He is never going to be cured from this condition, and therefore it would not be necessary to delay/ cancel surgery. He may be slightly more at risk of infection, due to immune dysfunction that accompanies these conditions, and the surgeons should be aware of this.

[Q: 942] OnExamination -
Haematology

A 41-year-old African man has a history of multiple episodes of sudden onset of severe abdominal pain and back pain lasting for hours. Each time this happens, his peripheral blood smear demonstrates numerous sickled erythrocytes.

A haemoglobin electrophoresis shows 94% Hgb S, 5% Hgb F, and 1% Hgb A2. He now has increasing pain in his right groin radiating to the anterior aspect of the thigh and to the knee. His temperature was 38° and examination of his hip revealed pain on internal rotation. A radiograph reveals irregular bony destruction of the femoral head.

The most likely organism to be responsible for these findings is?

- 1- Candida albicans
- 2- Clostridium perfringens
- 3- Group B streptococcus
- 4- Salmonella species
- 5- Yersinia pestis

Answer & Comments

Answer: 4- Salmonella species

Salmonella osteomyelitis is seen in patients with sickle cell anemia. Other organisms that are frequent causes for osteomyelitis with sickle cell anemia include Staphylococcus aureus and gram negatives such as Klebsiella.

Why Salmonella species predominate in patients with Sickle Cell Disease instead of

Staphylococcus aureus is a matter of debate. Etiology of Osteomyelitis Complicating Sickle Cell Disease. Pediatrics 1998;101;296-297

[Q: 943] OnExamination -
Haematology

A 17-year-old girl who had completed treatment for acute lymphoblastic leukaemia six months previously, presents with a short history of marked, right hip pain and associated limp.

What is the most likely diagnosis?

- 1- Avascular necrosis of the femoral head
- 2- Gout
- 3- Osteoarthritis
- 4- Pseudogout
- 5- Septic arthritis

Answer & Comments

Answer: 1- Avascular necrosis of the femoral head

Avascular necrosis of the femoral head can occur as a consequence of her treatment or the disorder itself. At age 17, osteoarthritis is particularly unlikely. Gout too is unlikely (considering she completed treatment six months ago) unless she had relapsed (high white cell count) or had some other risk factors. She would be considered to be no more likely to get septic arthritis or pseudogout than anyone who had not previously had acute lymphoblastic leukaemia, if in remission.

[Q: 944] OnExamination -
Haematology

An 82-year old man presents to his General Practitioner with a six month history of fatigue and increasing exertional dyspnoea.

Investigations show:

Haemoglobin 7.5 g/dL

MCV 112fL

White blood cells $3.12 \times 10^9/L$

Neutrophils 34%

Blasts 1%

Platelets $12 \times 10^9/L$

A bone marrow aspirate stained with Perl's stain showed ring sideroblasts.

What is the most likely diagnosis?

- 1- Aplastic anaemia
- 2- Chronic myeloid leukaemia
- 3- Metastatic bone marrow infiltration
- 4- Myelodysplastic syndrome
- 5- Myelofibrosis

Answer & Comments

Answer: 4- Myelodysplastic syndrome

The patient has a macrocytic anaemia, thrombocytopenia and neutropenia with a small number of circulating blasts. This suggests a diagnosis of myelodysplastic syndrome and is supported by the finding of ring sideroblasts in the marrow.

Ring sideroblasts contain an abnormally high concentration of iron usually stored in perinuclear mitochondria. Perl's stain (which stains for iron) shows this iron deposition as a dark ring around the margin of the nucleus.

[Q: 945] OnExamination - Haematology

A 68-year-old man complained of tiredness and lethargy. On examination there was 2 cm hepatomegaly and 7 cm splenomegaly.

Investigations show

Haemoglobin 17.4 g/dL (13.0-18.0)

White cell count $39.4 \times 10^9/L$ (4-11)

White cell differential:

Neutrophils $22.2 \times 10^9/L$ (1.5 - 7)

Lymphocytes $1.1 \times 10^9/L$ (1.5 - 4)

Monocytes $1.0 \times 10^9/L$ (0 - 0.8)

Eosinophils $0.4 \times 10^9/L$ (0.04 - 0.4)

Basophils $2.1 \times 10^9/L$ (0 - 0.1)

Metamyelocytes $1.2 \times 10^9/L$

Myelocytes $10.9 \times 10^9/L$

Myeloblasts $1.3 \times 10^9/L$

Nucleated RBC 3 per 100 rbc

Platelet count $585 \times 10^9/L$ (150 - 400)

What is the most likely diagnosis?

- 1- Acute myeloid leukaemia
- 2- Chronic myeloid leukaemia
- 3- Essential thrombocythaemia
- 4- Myelofibrosis
- 5- Primary proliferative polycythaemia (rubra vera)

Answer & Comments

Answer: 2- Chronic myeloid leukaemia

The presentation is typical with vague symptoms of malaise and splenomegaly. The blood film also shows the typical high White Cell Count and there are all stages of myeloid cell maturation present in the peripheral blood with the metamyelocytes suggesting CML. Thrombocythaemia is also seen in CML.

[Q: 946] OnExamination - Haematology

An 85-year-old patient from an elderly care home, experiences sudden onset of dyspnea and palpitations. A pulmonary ventilation-perfusion scan is performed and indicates a high probability for a perfusion defect involving a pulmonary arterial branch.

Which of the following findings or conditions is the one that is the most important factor favouring development of her complaint?

- 1- neutrophilia
- 2- Cirrhosis of the liver

- 3- Poor nutrition
- 4- An increased platelet count
- 5- Generalized atherosclerosis

Answer & Comments

Answer: 4- An increased platelet count

This would lead to a prothrombotic state, increasing the risk of pulmonary embolism. Cirrhosis, and possibly poor nutrition, would lead to decreased production of coagulation factors thus prolonging the INR. A neutrophilia would suggest infection leading to ventilation defect, and not a perfusion defect. Atherosclerosis would pre-dispose to arterial thrombo-embolus.

[Q: 947] OnExamination -
Haematology

B cell CLL

- 1- thrombocytopenia often autoimmune
- 2- reduced immunoglobulins are a risk for recurrent bacterial infections
- 3- Stage A disease should be treated with chemotherapy
- 4- late transformation to ALL occur in the majority of patients
- 5- diffuse infiltration of bone marrow indicates good prognosis

Answer & Comments

Answer: 2- reduced immunoglobulins are a risk for recurrent bacterial infections

Immune thrombocytopenia only in 2%. Hypogammaglobulinaemia predisposes to encapsulated bacteria eg pneumococcus/H influenzae - causes death in 30% cases. Two transformations in CLL - CLL/PL (10%) and Richter syndrome (5% = high grade non-hodgkins lymphoma). Treatment only for Stage B, C and A with clear evidence of progression.

[Q: 948] OnExamination -
Haematology

A 17-year-old male with glucose-6-phosphate dehydrogenase deficiency presents with tiredness and is noticed to be jaundiced. These features have developed since he developed a mild chest infection one week ago.

Which one of the following is the most likely haematological finding?

- 1- Haemoglobinuria
- 2- low mean cell volume
- 3- Positive direct antiglobulin test
- 4- Reduced reticulocyte count
- 5- Spherocytes present on blood film

Answer & Comments

Answer: 1- Haemoglobinuria

G6PD deficiency is a red cell enzymopathy that can lead to acute intravascular haemolysis after exposure to certain drugs, infection etc.

You would therefore get haemoglobinuria but would not get a positive direct antiglobulin test. The MCV and reticulocyte count would be high due to haemolysis.

There is a form of G6PD deficiency where there is a chronic low level haemolysis, where there are spherocytes seen- but the clinical information points to intravascular haemolysis after an infection.

[Q: 949] OnExamination -
Haematology

A 59-year-old male is referred with an abnormal full blood count. He had presented to his general practitioner with a flu like illness which has since subsided but a FBC revealed a platelet count of $800 \times 10^9 /l$ which has remained persistently elevated but with no other abnormality on the FBC. He is otherwise

entirely asymptomatic and no abnormalities are noted on examination.

Which of the following is the most appropriate treatment for this patient?

- 1- Aspirin
- 2- Anagrelide
- 3- Hydroxurea
- 4- Plateletpheresis
- 5- Observation

Answer & Comments

Answer: 5- Observation

There are a number of adverse prognostic markers for essential thrombocythemia: age > 60, symptomatology - particularly thrombosis and platelet count above 1500. Generally the prognosis is extremely good in ET with survival of over 2 decades expected. This patient would be regarded as low risk and hence observation only employed. The risk of bleeding can also be a problem and although you may think that aspirin would be appropriate the evidence is conflicting.

[Q: 950] OnExamination - Haematology

A 20-year-old caucasian student returns from Ghana with a spiking temperature and nocturnal sweats. She has 0.5% of red blood cells infected with Plasmodium falciparum.

Select one of the following answers relating to quinine therapy in this case:

- 1- quinine contraindicated in those taking mefloquine prophylactically
- 2- quinine must always be given parenterally initially
- 3- pregnancy is a contraindication for quinine
- 4- glucose level should be monitored in those on treatment with quinine
- 5- dose of quinine should be reduced in liver impairment

Answer & Comments

Answer: 4- glucose level should be monitored in those on treatment with quinine

Severe malaria is indicated by more than 1% of RBC infected. Hypoglycaemia is an important side-effect of quinine therapy and should be monitored in those having intravenous quinine. The initial dose should NOT be reduced in those severely ill with renal/hepatic impairment. Intravenous infusion of quinine reserved for severe or cerebral malaria (most deaths from M.falciparum occur in first 96 hours of starting treatment).

[Q: 951] OnExamination - Haematology

A 19-year-old man with glucose-6-phosphate dehydrogenase deficiency wishes to travel to Africa.

Which one of the following should he be advised to avoid?

- 1- primaquine
- 2- loperamide
- 3- mefloquine
- 4- ibuprofen
- 5- yellow fever vaccine

Answer & Comments

Answer: 1- primaquine

G6PD deficiency is inherited in an X-linked fashion and predisposes RBCs to haemolysis. Drugs recognised to predispose to acute haemolysis in G6PD deficiency include antimalarials such as Primaquine, sulphonamides, Nitrofurantoin and Nalidixic acid.

[Q: 952] OnExamination -
Haematology

You are called to A+E to assess a 21-year-old student who has presented with bloody diarrhoea. The diarrhoea started two weeks previously, and was associated with increasing nausea and malaise, and mild swelling of the lower limbs. She was having difficulty passing urine. She had eaten steak from the local butcher at a friends barbeque the day before developing diarrhoea. On examination she was pale, with evidence of petechiae over her legs. Her face appeared puffy. Blood pressure was 160/95.

On examination she was afebrile, but had a tachycardia, and crackles on inspiration at both lung bases. There was an old appendectomy scar in the right iliac fossa.

Investigations:

Haemoglobin 8.5 g/dL

White cell count $13.2 \times 10^9/L$

Neutrophils $9.5 \times 10^9/L$

Platelets $35 \times 10^9/L$

PT 12 sec

APTT 34 sec

Fibrinogen 4 g/dL

Serum sodium 139 mmol/L

Serum potassium 6.1 mmol/L

Serum urea 40 mmol/L

Serum creatinine 411 $\mu\text{mol/L}$

Serum albumin 27 g/L

Dipstick urine Blood ++ Protein +

What is the single most important next investigation to determine the diagnosis ?

- 1- ASO titres
- 2- Renal tract ultrasound
- 3- Stool culture
- 4- Transthoracic echocardiogram
- 5- Urine microscopy

Answer & Comments

Answer: 3- Stool culture

This patient has haemolytic uraemic syndrome (HUS). It typically presents with a triad of ARF, Microangiopathic haemolytic anaemia and thrombocytopenia with normal clotting. HUS is a complication of infection with verocytotoxin producing *Escherichia coli* usually of the serotype O157:H7. Toxins produced in the intestine enter the blood and bind to endothelial cells in target organs. Endothelial cell damage leads to platelet and fibrin deposition with resultant fragmentation of circulating red blood cells and microvascular occlusion. The syndrome has also been reported after infections with coxsackie, echovirus and shigella. HUS is characterised by the sudden onset of haemolytic anaemia with fragmentation of red blood cells, thrombocytopenia and acute renal failure after a prodromal illness of acute gastroenteritis often with bloody diarrhoea. Clinical signs include increasing pallor, haematuria, oliguria and purpura. Jaundice is occasionally seen. Hypertension may be present. Typical results show an anaemia, thrombocytopenia, and often a neutrophilia. Blood film shows fragmented erythrocytes. U and E - typical of acute renal failure. Normal coagulation and fibrinogen. Neurological complications- stroke, seizure and coma occur in 25% of patients, rarely pancreatitis, pleural and pericardial effusions. Approx 5% of patients will develop end stage renal failure. Long term renal sequelae range from proteinuria to chronic renal failure. Therapy is supportive with correction of anaemia, correction of uraemia by early dialysis, strict fluid balance and treatment of hypertension. Major differential diagnosis is 1) sepsis with DIC -presents with abnormalities of clotting parameters. 2)TTP - Thrombotic thrombocytopenic purpura presents with microangiopathic hemolytic anemia, thrombocytopenic purpura, neurologic abnormalities, fever, and renal disease.

Renal abnormalities tend to be more severe in HUS. Although once considered variants of a single syndrome, recent evidence suggests that the pathogenesis of TTP and HUS is different. Patients with TTP lack a plasma protease that is responsible for the breakdown of von Willebrand factor (vWF) multimers and these accumulate in the plasma. The activity of this protease is normal in patients with HUS. Until the test for vWF protease activity becomes available, differentiation between HUS and TTP is based on the presence of CNS involvement in TTP and the more severe renal involvement in HUS. In HUS, 90% of patients are children and a history of prodromal diarrheal illness is more common. The therapy of choice for TTP is plasma exchange with fresh frozen plasma.

[Q: 953] OnExamination - Haematology

A 53-year-old male is receiving treatment with imatinib for chronic myeloid leukaemia.

Which of the following is imatinib?

- 1- Inhibits p53
- 2- Inhibits HER
- 3- Inhibits guanylate cyclase
- 4- Inhibits MAP kinase
- 5- Inhibits tyrosine kinase

Answer & Comments

Answer: 5- Inhibits tyrosine kinase

Imatinib is an inhibitor of tyrosine kinase and is used in the treatment of conditions such as CML and GIST tumours. It inhibits TK on abl proto-oncogene, c-kit and the PDGF-R. In CML, the Philadelphia chromosome leads to a fusion protein of abl with bcr (breakpoint cluster region), termed bcr-abl. As this is now a continuously active tyrosine kinase, imatinib is used to decrease bcr-abl activity.

[Q: 954] OnExamination - Haematology

A 67-year-old woman presents with acute severe back pain. She is normally fit and well, but there is a strong family history of osteoporosis.

Hb 10.6 g/dl (12-16)

MCV 85 (80-90)

Calcium 2.9 mmol/l (2.2-2.6)

Phosphate 2.2 mmol/l (0.8-1.2)

alkaline phosphatase 126 iu/l (50-150)

Total protein 76g/l (60-83)

albumin 30g/l (35-45)

What is the most likely underlying diagnosis?

- 1- Metastatic disease
- 2- Multiple myeloma
- 3- Osteoporosis
- 4- Paget's disease
- 5- Sarcoidosis

Answer & Comments

Answer: 2- Multiple myeloma

This patient has hypercalcaemia/hyperphosphataemia and hyperglobulinaemia (The globulin level is raised at 46g/l total protein - albumin = 46. A Normal level should be below 36g/l). This together with normocytic anaemia and probable vertebral collapse would be highly suggestive of multiple myeloma. She needs serum immunoelectrophoresis, urinary Bence-Jones protein and bone marrow biopsy. The hyperphosphataemia in multiple myeloma is due to reduced renal excretion which may be directly due to renal impairment or interference with excessive protein load.

[Q: 955] OnExamination - Haematology

An 18-year-old Asian female is noted to have

gingival hypertrophy by her dentist.

Which of the following is most likely to be responsible for her presentation?

- 1- carbamazepine
- 2- scurvy
- 3- lead poisoning
- 4- phenytoin
- 5- sodium valproate

Answer & Comments

Answer: 4- phenytoin

The inclusion of 'asian' descent in this question is intended as a distractor. Gum hypertrophy may be seen in conditions such as acute myeloid leukaemias and with drugs such as phenytoin. Scurvy (vitamin C deficiency) is associated with bleeding gums. Lead toxicity is associated with pigmentation of the gingiva. Carbamazepine is not associated with gingival hyperplasia but recognised SEs include ataxia, drowsiness and blood dyscrasias.

[Q: 956] OnExamination - Haematology

A 22-year-old male student is admitted with weakness and tiredness. He has otherwise been well.

Examination reveals a petechial rash on the lower legs and conjunctival pallor. He takes no medication and denies any illicit drug use.

Investigations reveal:

Haemoglobin 4 g/dl

White cell count $1 \times 10^9/L$

Platelets $20 \times 10^9/L$

Clotting profile Normal

U+Es, liver function tests Normal

Which of the following is the likely diagnosis

- 1- Acute myeloid leukaemia
- 2- Acute lymphocytic leukaemia

- 3- Aplastic anaemia
- 4- Henoch-Schönlein Purpura
- 5- Hodgkin's lymphoma

Answer & Comments

Answer: 3- Aplastic anaemia

This patient appears to have complete suppression of all his marrow components suggesting aplastic anaemia. The acquired condition may be associated with drug therapy such as cytotoxics, Chloramphenicol, infections such as viral hepatitis, ionising radiation and chemicals.

[Q: 957] OnExamination - Haematology

A 30-year-old male patient presents with sudden deterioration and haematuria 15 minutes after starting blood transfusion.

His pulse rate is 120 beats per minute and blood pressure is 70/ 40 mmHg.

Which of the following is the most likely cause?

- 1- ABO incompatibility
- 2- Anaphylaxis to anaesthetic agents
- 3- Disseminated intravascular coagulation
- 4- Graft versus host disease
- 5- Rhesus incompatibility

Answer & Comments

Answer: 1- ABO incompatibility

Immediate life threatening reactions with intravascular haemolysis are caused by complement activating IgG or IgM antibodies. They are usually ABO antibodies and these reactions can occur after transfusion of a few millilitres of blood.

[Q: 958] OnExamination -
Haematology

A 52-year-old male presents with a history of lethargy and epistaxis over the last one month. Examination reveals numerous bruises over arms and legs, splenomegaly and retinal haemorrhages. A full blood count shows:

Haemoglobin 7 g/dL (11.5-16.5)

White cell count $14 \times 10^9/L$ (4-11)

Platelet count $20 \times 10^9/L$ (150-400)

His blood film reveals white cells predominantly myeloblasts and promyelocytes

Which one of the following investigations would be of most prognostic value?

- 1- Bone marrow aspiration
- 2- Bone marrow trephine biopsy
- 3- Cerebrospinal fluid examination
- 4- Cytogenetic karyotype
- 5- Immunophenotyping

Answer & Comments

Answer: 4- Cytogenetic karyotype

The history, full blood count results and the blood film is suggestive of Acute Myeloid Leukaemia, as there are numerous myeloblasts on film.

Of the answers given the Cytogenetic Karyotype is of most prognostic value. The cytogenetic karyotype divides people into three categories: Good Risk, Standard Risk and Poor Risk.

[Q: 959] OnExamination -
Haematology

A 60-year-old male presents with bruising and tiredness. Examination reveals 4 finger breadth splenomegaly and his results reveal:

Haemoglobin 11 g/dl (11.5-16)

White cell count $100 \times 10^9/L$

Platelets $900 \times 10^9/L$

Blood film reveals a neutrophilia, basophilia, numerous myelocytes and 4% myeloblasts

Which of the following is likely to be present in this patient?

- 1- BCR-ABL gene fusion only
- 2- Deletion chromosome 13
- 3- Deletion 11q13
- 4- Normal chromosomal analysis
- 5- Translocation 9;22

Answer & Comments

Answer: 5- Translocation 9;22

The Philadelphia chromosome (translocation 9;22) is present in approx 90% of subjects with CML. The molecular consequences of this translocation is the generation of the fusion bcr-abl gene which creates an abnormal protein stimulating white cell growth. Only 5% of cases have the bcr-abl fusion gene only without the typical Philadelphia chromosome.

Deletion of Ch13 is associated with a poorer prognosis in Multiple Myeloma.

[Q: 960] OnExamination -
Haematology

A 70-year-old female presents for investigation of fatigue and weight loss. Investigations reveal:

haemoglobin 9.0 g/dL (11.5 - 16.5)

white cell count $2.0 \times 10^9/L$ (4-11)

platelet count $250 \times 10^9/L$ (150 - 400)

total protein 74 g/L (61 - 76)

albumin 28 g/L (37 - 49)

urea 16 mmol/l (3-7)

creatinine 250 micromol/L (60 - 110)

plasma glucose 6.5 mmol/L (3.0 - 6.0)

urine dipstick analysis protein+ blood+

renal ultrasound normal

Which one of the following investigations would be most appropriate for this patient?

- 1- 24 hour urinary protein estimation
- 2- Measurement of anti-glomerular basement membrane (anti-GBM) antibodies
- 3- Measurement of anti-neutrophil cytoplasmic antibodies (ANCA)
- 4- plasma protein electrophoresis
- 5- renal angiography

Answer & Comments

Answer: 4- plasma protein electrophoresis

This patient may well have myeloma as reflected by the anaemia, leucopaenia and elevated non-albumin protein concentration. Thus plasma protein electrophoresis would be the investigation of choice in this patient.

[Q: 961] OnExamination -
Haematology

Which one of the following is true of IgE?

- 1- Is present in plasma in the same concentration as IgG
- 2- Is increased acutely in an asthmatic attack
- 3- Crosses the normal placenta
- 4- Is increased in the serum of atopic individuals
- 5- Is involved in type 2 hypersensitivity

Answer & Comments

Answer: 4- Is increased in the serum of atopic individuals

IgG is the predominant form of immunoglobulin in plasma at a concentration around 10,000 times that of IgE. IgG crosses the placenta to confer immunity to the fetus but IgE does not. IgE is involved in arming mast cells and basophils. IgE causes mast cells to release vasoactive amines, such as histamine, producing an inflammatory

response which can result in a type I hypersensitivity reaction. IgE is responsible for allergen-mediated diseases such as anaphylaxis, asthma and atopy. Total serum IgE is frequently increased in those with atopy but serum IgE does not rise acutely during an asthmatic attack.

[Q: 962] OnExamination -
Haematology

If a patient with chronic renal failure is treated with erythropoietin (EPO), *which of the following will be expected in this patient?*

- 1- Decreased pure red cell aplasia
- 2- Decreased risk of hypertension
- 3- Decreased risk of thrombosis
- 4- Increased well being
- 5- Reduced appetite

Answer & Comments

Answer: 4- Increased well being

Increased viscosity is seen in EPO therapy which may exacerbate hypertension and there is also increased risk of thrombosis. Pure red cell aplasia is a rare unwanted effect due to stimulation of antibodies by administered EPO which cross reacts with patient's endogenous EPO. Improvement in haemoglobin level results in the increased well being and better appetite.

[Q: 963] OnExamination -
Haematology

A 24-year-old male presents after developing a bluish discolouration of the body, lips and nails. He denies any relevant past medical history. Examination reveals a central cyanosis and a grey complexion.

Investigation revealed:

Haemoglobin 17.0 g/dL (13.0-18.0)

paO₂ 13.0 kPa (11.3-12.6)

SaO₂ (using an oximeter) 85% (>95)

What is the most likely diagnosis?

- 1- Argyria
- 2- Cyanotic congenital heart disease
- 3- Haemochromatosis
- 4- Methaemoglobinaemia
- 5- Methylene blue poisoning

Answer & Comments

Answer: 4- Methaemoglobinaemia

This patient is otherwise well and has no specific features of congenital heart disease (clubbing etc). He appears desaturated with sats of 85% yet good pO₂. This is a typical description of methaemoglobinaemia which is the accumulation of reversibly oxidised methaemoglobin causing reduced oxygen affinity of the Hb molecule with consequent cyanosis. It can occur due to an inherited condition or as a consequence of drugs such as nitrites.

Argyria is colloidal silver toxicity.

[Q: 964] OnExamination - Haematology

A 35-year-old lady with a history of two previous lower limb deep vein thromboses presents with a further DVT.

She has a thrombophilia screen performed, which shows the presence of lupus anticoagulant.

What is the best course of action?

- 1- Aspirin
- 2- Aspirin and Warfarin
- 3- Long term low molecular weight heparin
- 4- Warfarin for 6 months
- 5- Warfarin lifelong

Answer & Comments

Answer: 5- Warfarin lifelong

This patient has recurrent DVTs and has been shown to have the presence of the lupus anticoagulant. Under the circumstances, evidence would suggest that lifelong anticoagulation with warfarin is required maintaining an INR above 2.5.

[Q: 965] OnExamination - Haematology

A 60-year-old Chinese man has been started on quinine for leg cramps by his General Practitioner. He presents, a week later, with 5 days of darkened urine and 2 days of increasing breathlessness, back pain and fatigue. Investigations show a haemoglobin of 7.0 g/dl and raised reticulocyte count.

Which of the following best explain this drug reaction?

- 1- autoimmune haemolytic anaemia
- 2- glucose-6-phosphate dehydrogenase deficiency
- 3- hereditary spherocytosis
- 4- pyruvate kinase deficiency
- 5- sickle cell disease

Answer & Comments

Answer: 2- glucose-6-phosphate dehydrogenase deficiency

G6PDH (X-linked recessive) is seen in African, Mediterranean, Iraqi Jew, South East Asian and Chinese people and predisposes to a haemolytic anaemia reaction with drugs or infection. Implicated drugs include - aspirin, sulphonamides, antimalarials, and quinine / quinidine. The haemolytic anaemia is non-immune (DAT -ve). Pyruvate Kinase Deficiency is autosomal recessive and presents as a chronic haemolytic anaemia exacerbated by viral infections. Hereditary spherocytosis is

characterised by variable chronic non-immune haemolysis exacerbated by infections.

[Q: 966] OnExamination -
Haematology

You are asked to provide advice on a 35-year-old woman who is admitted under the maxillo-facial surgeons for extraction of wisdom teeth. The only concern was that she had developed prolonged bleeding following a tooth extraction 10 years previously and had required suturing. Besides this, she gave no other history of bleeding.

What is the most likely diagnosis?

- 1- factor IX deficiency
- 2- factor V Leiden
- 3- Factor XII deficiency
- 4- Primary antiphospholipid syndrome
- 5- von Willebrand's Disease

Answer & Comments

Answer: 5- von Willebrand's Disease

Not that much given away by this history just the issue of a prolonged bleed after prior dental extraction. The most likely diagnosis when considering this patient is von Willebrand's disease which is an autosomal dominant condition and is one of the commonest bleeding disorders. Most cases are mild, with bleeding after only mild injury, particularly mucosal membrane injuries. The condition is due to a reduction or structural abnormality of von Willebrand's factor, which has the dual role of promoting normal platelet function and stabilising coagulation factor VIII. Von Willebrand's disease can give normal results on screening tests, and diagnosis may require specialist investigation. Most patients with mild disease respond to desmopressin (DDAVP), but clotting factor concentrates are needed for a minority.

[Q: 967] OnExamination -
Haematology

In the consideration of Disseminated Intravascular Coagulation (DIC), which of the following statements is most correct?

- 1- The presence of DIC does not increase mortality from the underlying disease
- 2- In DIC associated with sepsis secondary to retained products of conception, treatment of antibiotics will alleviate the process
- 3- Organ failure is a common finding in DIC
- 4- The intrinsic pathway is not involved in the pathophysiology of DIC
- 5- There are no randomised control trials to guide treatment in DIC

Answer & Comments

Answer: 3- Organ failure is a common finding in DIC

DIC is caused by the enhanced and abnormally sustained generation of thrombin, and organ failure is a common finding, being as common as bleeding in DIC, and is likely to be due to fibrin deposition within the organ. The presence of DIC significantly increases mortality rates in affected patients, and treatment of the underlying cause of the DIC, e.g. sepsis, does not always lead to resolution of the condition. Recombinant human activated protein C has been shown to be effective in reducing mortality from DIC in patients with sepsis. A number of clinical trials have been published to guide treatment in DIC, one of which confirms the improved mortality with recombinant human activated protein C. Secondary bursts of thrombin formation seen in DIC are instigated by the intrinsic pathway.

For a well informed review see BMJ 2003;327:974-7.

[Q: 968] OnExamination -
Haematology

A 16-year-old girl with sickle cell disease presented with malaise and rapidly increasing dyspnoea. A full blood count showed:

Hb 5.1 g/dL

Reticulocyte count $5.5 \times 10^9/L$ (25-85)

What is the most cause?

- 1- Epstein-Bar virus
- 2- Hepatitis E virus
- 3- Human immunodeficiency virus
- 4- Human papillomavirus-16 (HPV 16)
- 5- Parvovirus B19

Answer & Comments

Answer: 5- Parvovirus B19

Aplastic crisis in SSA is caused by infection with the Parvovirus B19. The virus infects red cell progenitors in bone marrow, resulting in cessation of erythropoiesis and a very rapid drop in haemoglobin. The condition is self-limited, with bone marrow recovery occurring in 7-10 days, followed by brisk reticulocytosis.

[Q: 969] OnExamination -
Haematology

Which of the following patients with Hodgkin's disease has the worse prognosis?

- 1- 25-year-old man with inguinal lymphadenopathy
- 2- 25-year-old woman with mediastinal and inguinal lymphadenopathy
- 3- 25-year-old woman with mediastinal and inguinal lymphadenopathy and night sweats
- 4- 25-year-old man with mediastinal and inguinal lymphadenopathy and pruritis
- 5- 25-year-old man with cervical and mediastinal lymphadenopathy

Answer & Comments

Answer: 3- 25-year-old woman with mediastinal and inguinal lymphadenopathy and night sweats

Prognosis in Hodgkin's disease depends on staging and presence of B symptoms. Patient A has Stage IA disease (one lymph node area). Patient E has stage IIA disease (two lymph node areas on same side of diaphragm). Patient B and D have stage IIIA disease (disease in lymph nodes on both sides of diaphragm). Pruritis is not a B symptom and is not of prognostic significance. Patient C has stage IIIB disease, as night sweats are a B symptom.)

[Q: 970] OnExamination -
Haematology

A 17-year-old woman with non-Hodgkin's lymphoma underwent splenectomy for haemolytic anaemia. She understood that she had an enhanced risk of developing overwhelming pneumococcal sepsis and wished to know how long this risk would persist.

What is the duration of the risk?

- 1- Up to 6 months
- 2- Up to 1 year
- 3- Up to 5 years
- 4- 5 to 10 years
- 5- More than 10 years

Answer & Comments

Answer: 5- More than 10 years

The risk is thought to persist lifelong, and lifelong Penicillin prophylaxis is recommended.

[Q: 971] OnExamination -
Haematology

A 30-year-old woman presented with a deep

vein thrombosis. Her previous history included investigation for infertility. Investigations revealed: Haemoglobin 12.8 g/dl (12.5-16.5) White cell count $3.6 \times 10^9/L$ (4-11) Platelet count $35 \times 10^9/L$ (150-400)

Select one of the following investigations that is most likely to be abnormal?

- 1- Antiphospholipid antibodies.
- 2- Homocystine concentration
- 3- Platelet function test
- 4- Protein C concentration.
- 5- Indium-labelled white cell scan.

Answer & Comments

Answer: 1- Antiphospholipid antibodies.

The suggestion is that this patient has a thrombophilia, with a low platelet and white cell count. Together with the infertility a diagnosis of antiphospholipid syndrome is suggested. Although protein C deficiency is associated with thrombophilia, infertility is not a feature nor is thrombocytopaenia/leucopaenia.

Hyperhomocystinaemia is associated with arterial thrombosis.

[Q: 972] OnExamination - Haematology

A 55-year-old, asymptomatic woman with mild splenomegaly was found to have a platelet count of $650 \times 10^9/L$ on blood investigation. White blood cells and haemoglobin are within the normal range.

What is the next step in management?

- 1- Anagrelide
- 2- Hydroxycarbamide
- 3- Low dose aspirin
- 4- Observation
- 5- Plateletpheresis

Answer & Comments

Answer: 4- Observation

In essential thrombocytosis, low-risk patients have a risk of thrombosis similar to that of the age and sex-matched population and a very low risk of life-threatening bleeding, supporting close observation as the most sensible approach. Hydroxycarbamide is an adequate choice for patients 60 years of age or older who are otherwise in good health. For elderly patients with limited projected survival (less than 10 years) and who have problems with either drug compliance, 32P administration might be appropriate. Anagrelide should be offered to younger patients (less than 60) who are at high risk by virtue of a prior history of thrombosis. In patients who suffer from thrombotic episodes, especially episodes involving the microcirculation or large vessels, low-dose aspirin (100 mg/day) is usually administered. In severe, life-threatening episodes, rapid cyto-reduction may be achieved by plateletpheresis or by the administration of a single dose of 0.4 mg/kg of nitrogen mustard.

[Q: 973] OnExamination - Haematology

Which of the following conditions would be expected to be associated with a raised leukocyte alkaline phosphatase (LAP) score?

- 1- Chronic myeloid leukaemia
- 2- Infectious mononucleosis
- 3- Myelofibrosis
- 4- Pernicious anaemia
- 5- Thrombocytopaenic purpura

Answer & Comments

Answer: 3- Myelofibrosis

The LAP score aids in the differential diagnosis of chronic myelocytic leukemia (CML) versus leukemoid reaction; aids in the evaluation of

polycythemia vera, myelofibrosis with myeloid metaplasia, and paroxysmal nocturnal hemoglobinuria. Low scores have been associated with CML, PNH, thrombocytopenic purpura, and hereditary hypophosphatasia. High scores have been seen in polycythemia vera, myelofibrosis, aplastic anemia, mongolism, hairy cell leukemia, leukemoid reactions, and neutrophilia either physiological or secondary to infection. It is also increased in Hodgkin disease.

[Q: 974] OnExamination -
Haematology

A previously well 75-year-old lady presented with tiredness and a mildly raised lymphocyte count on her Full Blood Count. A blood film reports 'Smudge cells seen. Is this lady known to have Chronic Lymphocytic Leukaemia?'

What is the most appropriate next investigation to confirm this lady's diagnosis.

- 1- Bone marrow aspirate
- 2- Bone marrow trephine
- 3- Immunophenotyping
- 4- Serum immunoglobulins
- 5- Ultrasound scan

Answer & Comments

Answer: 3- Immunophenotyping

"A definitive diagnosis of CLL is based on the combination of a lymphocytosis and characteristic lymphocyte morphology and immunophenotype." British Committee for Standards in Haematology Guideline for CLL diagnosis 2005

The other tests are additional investigations all used in the workup of CLL.

[Q: 975] OnExamination -
Haematology

A 28-year-old man presented with recurrent nose bleeds and iron deficiency anaemia.

A Chest X-ray found a shadow over the right lung base and auscultation in this area revealed a bruit.

Which of the following is the most likely diagnosis?

- 1- Ehlers-Danlos syndrome
- 2- Hereditary haemorrhagic telangiectasia
- 3- Idiopathic thrombocytopenic purpura
- 4- von Willebrand's disease
- 5- Wegener's granulomatosis

Answer & Comments

Answer: 2- Hereditary haemorrhagic telangiectasia

This is hereditary haemorrhagic telangiectasia (Osler-Weber-Rendu syndrome) characterised by bleeding from telangiectasia on mucous membranes such as the nose, mouth and GI tract. Clinical examination reveals telangiectasia on the skin. AV malformation may be seen in the lung (as in this case) or brain.

[Q: 976] OnExamination -
Haematology

A 60-year-old lady with bruising is investigated and found to have the following Full Blood Count.

Haemoglobin 13 x 10⁹/L (11.5 - 16.5)

White cell count 6.3 x 10⁹/L (4 - 11)

Platelet count 15 x 10⁹/L (150 - 400)

She refuses to give consent to a bone marrow biopsy.

What is the most appropriate management plan?

- 1- Intravenous immunoglobulin
- 2- No treatment
- 3- Oral prednisolone
- 4- Platelet transfusion
- 5- Splenectomy

Answer & Comments

Answer: 3- Oral prednisolone

This lady most likely has Idiopathic Thrombocytopenic Purpura. The history should highlight any drug causes (not mentioned here) and a blood film would help exclude leukaemia. A bone marrow examination is useful especially in the older person. Platelet transfusion would not be helpful without treating the underlying cause. No treatment is often an option but this lady is older and has bruising. Given the circumstances the best management plan is to treat with steroid.

[Q: 977] OnExamination - Haematology

A 16-year-old boy presents with a haemarthrosis that developed in his left knee following an injury in the garden. His investigations show:

Platelet count $260 \times 10^9/L$ (150 - 400)

Prothrombin time 13 s (11.5 - 15.5)

Activated partial thromboplastin time 80 s (30 - 40)

Factor VIII 110 IU/dL (50 - 150)

Which of the following is the most likely diagnosis?

- 1- Antiphospholipid syndrome
- 2- Antithrombin III deficiency
- 3- Haemophilia A
- 4- Haemophilia B
- 5- von Willebrand's disease

Answer & Comments

Answer: 4- Haemophilia B

An elevated APTT could be due to treatment with heparin, haemophilia, von Willebrand's disease or antiphospholipid syndrome. A normal Factor VIII would suggest Haemophilia B where there is lack of Factor IX. A prolonged

APTT can be seen in von Willebrand's disease but Factor VIII activity would be low. The presentation is not consistent with antiphospholipid syndrome and would also, typically, be associated with thrombocytopenia.

[Q: 978] OnExamination - Haematology

A 14-year-old boy presents with excessive bleeding from a tooth cavity following an extraction at the dentist. His investigations show:

Haemoglobin $13.2 \times 10^9/L$ (13 - 18)

Platelet count $260 \times 10^9/L$ (150 - 400)

White cell count $8 \times 10^9/L$ (4 - 11)

Prothrombin time 14 s (11.5 - 15.5)

Activated partial thromboplastin time 45 s (30 - 40)

Factor VIII 45 IU/dL (50 - 150)

Which of the following is the most likely diagnosis?

- 1- Disseminated intravascular coagulation
- 2- Haemophilia A
- 3- Haemophilia B
- 4- Idiopathic thrombocytopenic purpura
- 5- von Willebrand's disease

Answer & Comments

Answer: 5- von Willebrand's disease

This young boy with excessive bleeding has a slightly raised APTT and slightly reduced Factor VIII. Haemophilia is therefore unlikely and von Willebrand's is the most likely. DIC and ITP would typically be associated with thrombocytopenia.

[Q: 979] OnExamination - Haematology

A 56-year-old man is found to have a

macrocytic anaemia with a megaloblastic bone marrow.

Which of the following causes of macrocytosis is the most likely cause?

- 1- Alcohol
- 2- Aplastic anaemia
- 3- Folate deficiency
- 4- Myelodysplasia
- 5- Reticulocytosis

Answer & Comments

Answer: 3- Folate deficiency

A megaloblastic bone marrow occurs in vitamin B₁₂ or folate deficiency and with some cytotoxic drugs. The other causes of macrocytosis do not cause a megaloblastic bone marrow appearance.

[Q: 980] OnExamination - Haematology

A 34-year-old Asian lady presented with tiredness and lethargy. Her full blood count shows:

Haemoglobin 10.3 g/dl (11.5 - 16.5)

Platelet count 320 x 10⁹/L (150 - 400)

White Cell Count 10.6 x 10⁹/L (4 - 11)

MCV 68 fl (80 - 96)

HbA₂ 5.2% (2 - 3)

Which of the following is the most likely diagnosis?

- 1- Acute myeloid leukaemia
- 2- Beta-thalassaemia major
- 3- Beta-thalassaemia trait
- 4- Hereditary spherocytosis
- 5- Sickle cell disease

Answer & Comments

Answer: 3- Beta-thalassaemia trait

Microcytic anaemia would immediately raise the suspicion of iron deficiency perhaps from GI or menstrual blood loss. However, the MCV here is disproportionately low. This combined with a raised HbA₂ makes the diagnosis of beta-thalassaemia trait the most likely diagnosis.

"The diagnosis of beta thalassemia minor usually is suggested by the presence of an isolated, mild microcytic anemia, target cells on the peripheral blood smear, and a normal red blood cell count. An elevation of Hb A₂ (2 alpha-globin chains complexed with 2 delta-globin chains) demonstrated by electrophoresis or column chromatography confirms the diagnosis of beta thalassemia trait. The Hb A₂ level in these patients usually is approximately 4-6%. In rare cases of concurrent severe iron deficiency, the increased Hb A₂ level may not be observed, although it becomes evident with iron repletion. The increased Hb A₂ level also is not observed in patients with the rare delta-beta thalassemia trait."

[Q: 981] OnExamination - Haematology

A 28-year-old, primigravid woman developed a swollen painful left leg at 12 weeks gestation.

Doppler ultrasound of her leg venous system showed a left popliteal vein thrombosis.

Which one of the following treatments is associated with the greatest risk to the foetus?

- 1- Aspirin
- 2- Intravenous unfractionated Heparin
- 3- Subcutaneous low molecular weight Heparin
- 4- Subcutaneous unfractionated Heparin
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

Oral anticoagulants are teratogenic and should not be given in the first trimester of pregnancy.

Oral anticoagulants cross the placenta, and increase the risk of fetal and placental haemorrhage. Aspirin appears to be relatively safe as are heparins.

[Q: 982] OnExamination - Infectious disease

The antibiotic combination Quinipristin and Dalfopristin are

- 1- effective against resistant mycobacterium TB.
- 2- indicated in subjects with chronic renal impairment.
- 3- particularly effective in the treatment of pseudomonas infection in Cystic fibrosis.
- 4- administered orally.
- 5- Effective against multi-resistant Staphylococcus aureus

Answer & Comments

Answer: 5- Effective against multi-resistant Staphylococcus aureus

Quinipristin and Dalfopristin are a synergistic combination of a streptogramin A and B respectively. They are effective against Gram positive aerobes and are particularly useful against resistant Streptococcus pneumoniae and Staphylococcus aureus. They can only be administered via a central line.

[Q: 983] OnExamination - Infectious disease

The drug of choice for the treatment of Chlamydia trachomatis infection during pregnancy is:

- 1- Metronidazole.
- 2- Cephazolin
- 3- Amoxicillin
- 4- Tetracycline
- 5- Clindamycin

Answer & Comments

Answer: 3- Amoxicillin

Chlamydia infection in the non-pregnant state is usually treated with a tetracycline, or with

erythromycin - although more recently, amoxicillin has been found to be as effective as the latter.

During pregnancy, tetracycline therapy is contraindicated because of incorporation into fetal bones and teeth. Thus, for the options listed, amoxicillin is the drug of choice.

[Q: 984] OnExamination - Infectious disease

Which one of the following measures would be most effective in reducing transmission of E coli O157:H7 during an outbreak of diarrhea caused by this organism?

- 1- Drinking only boiled water
- 2- Ensuring that meat products are thoroughly cooked
- 3- Giving antibiotics to individuals who are positive for Escherichia coli on stool culture
- 4- Hand washing before preparing food
- 5- Isolation of individuals with diarrhoea

Answer & Comments

Answer: 2- Ensuring that meat products are thoroughly cooked

Cattle are a major reservoir of Escherichia coli O157:H7 and contaminated meat is the most commonly implicated source of outbreaks. Raw meat should be separated from cooked and ready to eat food. Hands should be washed after handling raw meat. Antibiotics are not routinely indicated and patients should be educated on personal hygiene.

[Q: 985] OnExamination - Infectious disease

A young teenager presents with fever and headache. He has received oral Amoxicillin for 3 days.

Which of the following CSF findings would exclude a partially treated meningitis?

- 1- Negative gram stain
- 2- A CSF glucose of 45% of blood glucose
- 3- A white cell count of 50
- 4- A negative CSF culture
- 5- Negative Kernig's Sign

Answer & Comments

Answer: 3- A white cell count of 50

The assessment of children with suspected bacterial meningitis who have already received antibiotic therapy is a diagnostic conundrum. This applies to about 25-50% of children, so it is an important problem. Partial treatment may reduce the incidence of positive CSF gram stains to <60%, and it also reduces the ability to grow the bacteria, particularly meningococcus. CSF glucose, protein, neutrophils and bacterial antigen testing or PCR should be completely unaffected.

[Q: 986] OnExamination - Infectious disease

The antibiotic combination Quinipristin and Dalfopristin are

- 1- effective against resistant mycobacterium TB.
- 2- indicated in subjects with chronic renal impairment.
- 3- particularly effective in the treatment of pseudomonas infection in Cystic fibrosis.
- 4- administered orally.
- 5- Effective against multi-resistant Staphylococcus aureus

Answer & Comments

Answer: 5- Effective against multi-resistant Staphylococcus aureus

Quinipristin and Dalfopristin are a synergistic combination of a streptogramin A and B respectively. They are effective against Gram

positive aerobes and are particularly useful against resistant Streptococcus pneumoniae and Staphylococcus aureus. They can only be administered via a central line.

[Q: 987] OnExamination - Infectious disease

Which of the following statement is true of infections with Mycobacterium tuberculosis:

- 1- non-sputum producing patients are non-infectious
- 2- a positive tuberculin test indicates active disease
- 3- lymph node positive disease requires longer treatment than pulmonary disease
- 4- in pregnant women treatment should not be given until after delivery
- 5- pyrazinamide has high activity against active extracellular organisms

Answer & Comments

Answer: 1- non-sputum producing patients are non-infectious

Only untreated smear positive pulmonary TB is likely to be infectious. Active disease may be indicated by grade III/IV response to tuberculin. 80% of individuals with history of BCG vaccination have grade I/II response. All forms of pulmonary TB may be treated equally except tuberculous pleural effusion which may require drainage (with large effusions causing breathlessness) and adjunct corticosteroids to delay reaccumulation. Length of treatment for other forms are bone TB 9 months, meningitis 1 year, drug resistance 2 years. Streptomycin has high activity against extracellular organisms whilst pyrazinamide have high activity against intracellular organisms.

[Q: 988] OnExamination - Infectious disease

Twenty one people are on a Nile boat cruise and present one week into their cruise with

diarrhoea.

What is the most likely causative organism?

- 1- Campylobacter
- 2- Cryptosporidium parvum
- 3- Entamoeba histolytica
- 4- Giardia lamblia
- 5- Shigella species

Answer & Comments

Answer: 5- Shigella species

The most likely organism from this history is Shigella which accounts for approx 15% of all travellers diarrhoea.

[Q: 989] OnExamination - Infectious disease

An 18-year-old male presented with a two-week history of dysuria and purulent penile discharge. Gram stain of a urethral swab showed Gram-negative intracellular diplococci.

What specific treatment should he receive?

- 1- Cefixime
- 2- Cephadrine
- 3- Ciprofloxacin
- 4- Co-amoxiclav
- 5- Crystalline penicillin

Answer & Comments

Answer: 1- Cefixime

Neisseria gonorrhoea occurs in young adults and is often preceded by a migratory tendonitis or arthritis. Gram's stain is positive in 25% and culture positive in 50%. Current UK guidelines recommend first-line treatment with either cefotaxime, cefixime or spectinomycin may be given (as a stat dose). Fluoroquinolones are no longer used as first-line treatment due to the high rate of resistance.

"In the UK, the majority of patients with gonorrhoea are treated in dedicated sexual health clinics. The current recommendation is for ceftriaxone or cefixime as first line therapy; no resistance to either drug has yet been reported in the UK. Levels of spectinomycin resistance in the UK are less than 1%, which would make it a good choice in theory, but intramuscular spectinomycin injection is very painful.

Azithromycin (given as a single dose of 2g) is recommended if there is concurrent infection with chlamydia. A single dose of oral ciprofloxacin 500mg is effective if the organism is known to be sensitive, but fluoroquinolones were removed from the UK recommendations for empirical therapy in 2003 because of increasing resistance rates. In 2005, resistance rates for ciprofloxacin were 22% for the whole of the UK (42% for London, 10% for the rest of the UK)."

[Q: 990] OnExamination - Infectious disease

A 35-year-old man presented with cellulitis of his right leg. On examination he was mildly confused and febrile (40.1?) with a pulse was 120 / minute and BP 80/55 mmHg. He was treated with intravenous benzylpenicillin and flucloxacillin. Group A Streptococcus was isolated from two sets of blood cultures. There was no significant clinical improvement after 24 hours.

What antibiotic should be added?

- 1- Ciprofloxacin
- 2- Clindamycin
- 3- Gentamicin
- 4- Rifampicin
- 5- Vancomycin

Answer & Comments

Answer: 2- Clindamycin

The patient has a severe cellulitis with features of Streptococcal toxic shock syndrome. Streptococcal TSS is mediated via Streptococcal exotoxins. Although clindamycin is a bacteriostatic antibiotic, it acts by switching-off protein synthesis within bacteria; this in turn will lead to decreased exotoxin expression, thereby removing the mediators of TSS.

[Q: 991] OnExamination - Infectious disease

Which of the following statements concerning zoonotic diseases is true?

- 1- Brucellosis is characterised by neutrophil leucocytosis.
- 2- Brucellosis is a recognised cause of spondylitis.
- 3- Toxoplasmosis causes visceral larva migrans.
- 4- Toxoplasmosis causes vasculitic anterior uveitis.
- 5- Serological evidence of toxoplasmosis is rare in adults.

Answer & Comments

Answer: 2- Brucellosis is a recognised cause of spondylitis.

Answer: 2) Brucellosis is a recognised cause of spondylitis.

Brucellosis is a zoonosis, spreading from infected animals particularly cattle. There are 4 species, melitensis, abortus, suis, and canis. Pasteurisation of milk has decreased the incidence in the UK dramatically. Brucella are gram negative bacilli which are fastidious. There is usually a history of exposure, and the symptoms are rather non-specific with fever, malaise, arthralgia and depression. 35% have hepatosplenomegaly. Leukopenia is common, and 75% have a positive blood culture (90% of bone marrow cultures will be positive). Toxoplasma is most frequent in farming

communities where contact occurs with cats, and patients eat raw meat. Clinical manifestations include: focal choroidoretinitis, granulomatous uveitis, optic atrophy, retinal detachment, cataract, posterior uveitis and glaucoma.

[Q: 992] OnExamination - Infectious disease

Which of the following statements is true of psittacosis (ornithosis):

- 1- It is only a risk from contact with psittacines (parrots), not other birds
- 2- It usually causes many polymorphs to be present in the sputum
- 3- It is more of a risk to children than to adults who are exposed to birds
- 4- It does spread from person to person
- 5- Infection responds rapidly to penicillin therapy

Answer & Comments

Answer: 4- It does spread from person to person

Chlamydia psittaci is endemic in birds including psittacine birds, canaries, finches, pigeons and poultry. Pet owners, vets and zoo keepers are most at risk. Rare in children. Person-person transmission occurs especially in a hospital environment. Sputum Gram stain reveals a few leucocytes and no predominant bacteria. Few signs/few lab/xray findings. Positive serology with complement-fixing antibodies. treat with tetracycline.

[Q: 993] OnExamination - Infectious disease

Which of the following is a feature of Vancomycin-resistant enterococci?

- 1- cause resistant infective diarrhoea
- 2- produce an enzyme that inactivates vancomycin

- 3- may be found in healthy community volunteers not recently hospitalized
- 4- high dose ampicillin is the treatment of choice
- 5- are commonly vancomycin-dependent

Answer & Comments

Answer: 3- may be found in healthy community volunteers not recently hospitalized

a-When they cause clinical problems they are usually UTI, bacteraemia, wound infections, neonatal infections, endocarditis etc. b-They alter peptidoglycan precursors used to build cell walls. Vancomycin binds to D-ala-D-ala but the resistant enterococci have D-ala-D-lac or D-ala terminating precursors. They acquire genes that produce enzymes to change the precursors. c-2% in UK general practice, 28% in Belgium. Community reservoir in meat, poultry and cheese. d-only if the MIC of ampicillin is not too high. Anecdotal evidence exists for its use in E. faecalis endocarditis. (20g / day) e-Some strains only. An explanation for this curious process is that there is an inability to produce cell walls because the vancomycin-sensitive precursor genes have been turned off and the resistant ones only appear in the presence of vancomycin. (Source: Am J Med 1997;102:284-293)

[Q: 994] OnExamination - Infectious disease

A 62-year-old lady is due to attend her dentist for a hygiene appointment for scaling. She has a history of mitral valve prolapse with regurgitation and is allergic to penicillin.

Which of the following antibiotics would be the most appropriate choice for prophylaxis in this lady?

- 1- Oral clindamycin
- 2- Oral doxycycline

- 3- Oral erythromycin
- 4- Oral ofloxacin
- 5- No antibiotic prophylaxis

Answer & Comments

Answer: 1- Oral clindamycin

Oral clindamycin is recommended for penicillin allergic patients where prophylaxis is required against infective endocarditis.

[Q: 995] OnExamination - Infectious disease

A 57-year-old woman develops a blistering rash around the midriff and is diagnosed with herpes zoster. She is treated with acyclovir.

Through inhibition of which of the following does acyclovir function?

- 1- Integrase
- 2- Polymerase
- 3- Protease
- 4- Reverse transcriptase
- 5- Thymidine kinase

Answer & Comments

Answer: 2- Polymerase

Acyclovir is a synthetic purine nucleotide analogue and as such is a specific inhibitor of herpesvirus DNA polymerase.

[Q: 996] OnExamination - Infectious disease

An 80-year-old man with a 5 year history of diet controlled type 2 diabetes mellitus presents with a one month history of cough and weight loss. He was a non-smoker and had difficulty expectorating. Investigation revealed a HbA1c of 7% but his chest X-ray showed a cavitating left apical shadow.

Which of the following investigations would be most useful in establishing the cause of this lesion?

- 1- bronchoscopy
- 2- CT scan of the chest
- 3- Gastric aspirate for acid-fast bacilli
- 4- Percutaneous lung biopsy
- 5- Sputum for acid-fast bacilli

Answer & Comments

Answer: 1- bronchoscopy

The differential diagnosis of cavitating lung lesions is shown below. The most likely diagnosis in this non-smoking man is post primary tuberculosis as a result of reactivation of quiescent disease. He has several risk factors including increasing age and diabetes. The patient is unable to produce sputum therefore undertaking a bronchoscopy with bronchial washings for microscopy staining and culture is the investigation of choice. Gastric lavage for AFB is unpleasant for the patient has a lower yield than bronchoscopy and is therefore rarely undertaken now. Causes of Cavitating Masses on CXR: (a) Lung abscess (b) Tuberculosis (c) Fungal infection (eg. Histoplasmosis, Coccidioidomycosis) (d) Malignancy (e) Wegener's Granulomatosis) commonly (f) Rheumatoid Arthritis) multiple (g) Infarction)

[Q: 997] OnExamination - Infectious disease

A 30-year-old schoolteacher is admitted with headache, photophobia and neck stiffness. His temperature is 39.0°C, pulse rate 120 beats/min and he has no skin rash or focal neurological signs his Glasgow coma scale is 15/15. A CT scan shows no contraindication to lumbar puncture. CSF is obtained and Gram stain shows gram-positive cocci, subsequent culture confirms a pneumococcal meningitis.

What chemoprophylaxis should be offered to his pupils?

- 1- Azithromycin
- 2- Ceftriaxone
- 3- Ciprofloxacin
- 4- no chemoprophylaxis required
- 5- Rifampicin

Answer & Comments

Answer: 4- no chemoprophylaxis required

Chemoprophylaxis is not normally indicated for close contacts of those with pneumococcal meningitis. Chemoprophylaxis with Rifampicin, Ceftriaxone, Ciprofloxacin or azithromycin is used for meningococcal meningitis. Close contacts of Haemophilus influenzae meningitis should receive rifampicin; children under 2 years should be vaccinated.

[Q: 998] OnExamination - Infectious disease

Which of the following is true of Giardia lamblia infection?

- 1- is often symptomatic
- 2- is usually spread by contaminated meats
- 3- is eradicated by mebendazole
- 4- causes steatorrhoea
- 5- diagnosed by stool culture

Answer & Comments

Answer: 4- causes steatorrhoea

Usually acquired by the faeco-oral route. Many individuals excreting cysts are asymptomatic and are thus carriers. Others have diarrhoea, steatorrhoea, abdominal pain and nausea. Diagnosed by stool microscopy - if negative, parasite found in duodenal aspirates or biopsy. Testing of serum antibodies against G lamblia trophozoites is not useful in

diagnosing current infection. Eradicate with metronidazole (or quinacrine, tinidazole, ornidazole, furazolidone, paromomycin). Mebendazole is used in treating hookworm infections eg ascaris, whipworm and threadworm.

[Q: 999] OnExamination - Infectious disease

Which of the following is true concerning Whooping cough (pertussis)?

- 1- is a greater threat to children during the second 6 months of life, after maternal antibody has declined, than during the first 6 months
- 2- may lead to hemiplegia
- 3- is characteristically associated with a polymorph leucocytosis
- 4- is associated with convulsions less frequently than is the case with other febrile conditions
- 5- rapidly resolves with antibiotic treatment

Answer & Comments

Answer: 2- may lead to hemiplegia

Whooping cough (pertussis) is caused by the bacterium *Bordetella pertussis*. *B. pertussis* is a very small Gram-negative aerobic coccobacillus that appears singly or in pairs. Infection is characterised by paroxysms of coughing. Lymphocytosis is typically found. Hemiplegia is a recognised effect of severe whooping cough. The pertussis vaccine is estimated to be 63% to 94% effective in the DPT shot.

[Q: 1000] OnExamination - Infectious disease

Varicella-Zoster infection :

- 1- Gamma Interferon is an effective treatment.

- 2- produces latent infection within the anterior horn cells
- 3- causes urinary incontinence
- 4- causes congenital limb deformity
- 5- associated pneumonitis is equally common in smokers and nonsmokers

Answer & Comments

Answer: 4- causes congenital limb deformity

Varicella-Zoster infection causes Herpes Zoster and Chicken Pox.

Herpes Zoster is due to reactivation of the virus lying dormant in the cells of dorsal root ganglion. Autonomic involvement can cause urinary retention. Pregnancy increases risk of pneumonitis. Chicken pox in the first and second trimester can produce a syndrome of skin scarring, hypoplastic limbs, eye and CNS impairments. Pneumonitis is uncommon in children, with incidence of 0.3% in immunocompetent adults. The risk is higher in smokers. Antiviral treatment include acyclovir and vidarabine.

[Q: 1001] OnExamination - Infectious disease

A 50-year-old man presented to hospital feeling generally unwell for 3 days. He had returned from a business trip to Thailand six weeks previously and had taken mefloquine as prophylaxis against malaria. On examination he was afebrile, temperature 36.5 C, Pulse was 100/minute and regular, his BP was 85/60 mm Hg.

Investigations showed:

Hb 14.2 g/dL (13.0-18.0)

WBC $19.0 \times 10^9/L$ (4- 11)

Neutrophils $18.0 \times 10^9/L$ (1.5-7.0)

AST 72 IU/L (1-31)

Alkaline phosphatase 255 (45-105)

What is the most likely diagnosis?

- 1- Acute HIV infection (seroconversion illness)
- 2- Dengue fever
- 3- Gram-negative bacteraemia
- 4- Hepatitis B
- 5- Mefloquine-induced hepatitis

Answer & Comments

Answer: 3- Gram-negative bacteraemia

A difficult question. The neutrophilia essentially excludes most viral causes. The presentation is not typical of acute HIV (fever, pharyngitis, rash & lymphadenopathy). Mefloquine can cause abnormal LFTs, but is not common. Even though the patient is afebrile, the likeliest diagnosis is therefore Gram-negative bacteraemia.

[Q: 1002] OnExamination - Infectious disease

Which of the following is correct regarding Herpes simplex encephalitis?

- 1- shows a peak incidence in the Autumn
- 2- is associated with a polymorphonuclear pleocytosis in the CSF
- 3- produces a diffuse, evenly distributed inflammation of cerebral tissues
- 4- produces a typical EEG pattern with lateralised periodic discharges at 2 Hz
- 5- should be treated with acyclovir as soon as the diagnosis is confirmed by urgent CSF viral antibody titres

Answer & Comments

Answer: 4- produces a typical EEG pattern with lateralised periodic discharges at 2 Hz

This EEG pattern is seen but not diagnostic. Winter is the peak incidence. A lymphocytosis is characteristic in the CSF. Temporal lobe location is typical not diffuse. Immediate treatment required on clinical suspicion - don't wait!

[Q: 1003] OnExamination - Infectious disease

A 27-year-old pop singer presented with a two month history of loose motions and weight loss. He underwent a HIV antibody test and was found to be positive.

The presence of which of the following diseases indicates a diagnosis of AIDS?

- 1- Brucellosis
- 2- Glandular fever
- 3- Lyme disease
- 4- Oral candidiasis
- 5- Pulmonary Tuberculosis

Answer & Comments

Answer: 5- Pulmonary Tuberculosis

AIDS defining diseases are:

Cytomegalovirus disease (other than liver, spleen, or nodes)

Cytomegalovirus retinitis (with loss of vision)

Encephalopathy, HIV-related

Herpes simplex: chronic ulcer(s) (>1 month's duration); or bronchitis, pneumonia, or esophagitis

Histoplasmosis, disseminated or extrapulmonary

Isosporiasis, chronic intestinal (>1 month's duration)

Kaposi's sarcoma

Lymphoma, Burkitt's (or equivalent term)

Lymphoma, primary, of brain

Mycobacterium avium complex or M. kansasii, disseminated or extrapulmonary

Mycobacterium tuberculosis, any site (pulmonary or extrapulmonary)

Mycobacterium, other species or unidentified species, disseminated or extrapulmonary

Pneumocystis carinii pneumonia
 Pneumonia, recurrent
 Progressive multifocal leukoencephalopathy
 Salmonella septicemia, recurrent
 Toxoplasmosis of brain
 Wasting syndrome due to HIV

[Q: 1004] OnExamination -
 Infectious disease

Which of the following is least true regarding IgA nephropathy?

- 1- Is the most common glomerulonephritis in the world
- 2- Predominantly affects young men
- 3- Commonly follows a sore throat
- 4- May be associated with a rash and arthritis
- 5- Light chains may be found in the urine

Answer & Comments

Answer: 5- Light chains may be found in the urine

IgA nephropathy (Berger's disease) is the most common glomerulonephritis worldwide, and characteristically affects young males, presenting with frank haematuria after an episode of pharyngitis. However it may also present with proteinuria, microscopic haematuria, renal failure or hypertension. It is probably part of a spectrum of disease with Henoch Schoenlein Purpura, which presents with arthritis, rash, abdominal pain and nephritis. In both there are mesangial IgA deposits in the kidney.

[Q: 1005] OnExamination -
 Infectious disease

A 29-year-old man is diagnosed with pulmonary tuberculosis. A blood sample is sent to determine his acetylator status prior to starting therapy. This showed that he was a

fast acetylator. He was subsequently started on anti-tuberculous therapy that included isoniazid.

Which of the following statements is correct?

- 1- There is an increased risk of convulsions
- 2- There is an increased risk of drug resistance
- 3- There is an increased risk of hepatitis
- 4- There is an increased risk of megaloblastic anaemia
- 5- There is an increased risk of peripheral neuropathy

Answer & Comments

Answer: 3- There is an increased risk of hepatitis

Isoniazid is metabolized primarily by acetylation and dehydrazination. The rate of acetylation is genetically determined. Approximately 50 percent of Blacks and Caucasians are "slow acetylators", and the rest are "rapid acetylators"; the majority of Eskimos and Orientals are "rapid acetylators". Fast acetylation leads to higher blood levels of the toxic metabolite acetylisoniazid and thus, to an increase in toxic reactions - hepatitis which is x250 more common than in slow acetylators.. Fast acetylators on the other hand require higher doses but there increased tubercle resistance is not a problem.

[Q: 1006] OnExamination -
 Infectious disease

Twenty of thirty patients in an adult ward develop colicky abdominal pain and diarrhoea without vomiting between 21:00 and 01:00 hrs. Meat stew was served for lunch at noon.

Which of the following is the likely diagnosis?

- 1- Bacillus cereus
- 2- Clostridium perfringens
- 3- Enterotoxigenic Escherichia coli
- 4- Enterovirus

5- Staphylococcus aureus

Answer & Comments

Answer: 2- Clostridium perfringens

This food poisoning with no vomiting and an incubation period between 9-13 hrs incubation is typical of Clostridium perfringens. The history is too long for a typical Staphylococcus aureus infection (vomiting a typical feature, incubation period 1-6 hrs) and rather short of enterovirus (24 hrs). The predominant symptom of B.Cereus (inc period 1-5 hrs) is marked vomiting with diarrhoea occasionally seen. Escherichia coli infection has an incubation period of 12-24hrs and is also associated with marked vomiting. Supportive treatment is all that is generally required with symptoms resolving after 24 hrs.

[Q: 1007] OnExamination - Infectious disease

You are considering starting a patient on Griseofulvin.

Which of the following statements concerning its pharmacology is true?

- 1- It is active against Candida albicans.
- 2- It is active against aspergillus.
- 3- It should not be used in renal failure.
- 4- It used for a maximum of 2 weeks.
- 5- It is associated with drug-induced Stevens Johnson syndrome.

Answer & Comments

Answer: 5- It is associated with drug-induced Stevens Johnson syndrome.

Answer: 5) It is associated with drug-induced Stevens Johnson syndrome.

For griseofulvin and Steven-Johnson syndrome read J Emerg Med 1984;2:129-135. Many

other drugs are implicated in causing Steven-Johnson syndrome.

Griseofulvin is not active against Candida albicans. It is active against trichophytons (tinea) and other dermatophytes. It is metabolised in the liver (note also it's an enzyme inducer). Only 0.1-0.2% excreted in urine. Treatment with griseofulvin is often needed for a long period, sometimes years, depending on the rate of nail growth.

[Q: 1008] OnExamination - Infectious disease

A 17-year-old girl presents with 3 day history of vaginal discharge.

What is the most likely causative organism?

- 1- Candida albicans
- 2- Bacterial vaginosis
- 3- Chlamydia trachomatis
- 4- Neisseria gonorrhoea
- 5- Trichomonas vaginalis

Answer & Comments

Answer: 1- Candida albicans

There is very little information given in this young girl's case save for the 3 day history of vaginal discharge. There is no information given with regard to pruritus, sexual exposure or whether the discharge is malodorous. Without this information it's rather pot luck, but the most likely organism would be candida as a cause of a vaginal discharge with few other symptoms.

[Q: 1009] OnExamination - Infectious disease

An 82-year-old female is reviewed as the staff of the nursing home in which she resides are concerned regarding a vaginal discharge. She has been in the nursing home for the last one year with a profound Alzheimer's dementia.

Culture of the discharge reveals *Neisseria gonorrhoeae*.

Which is the most appropriate course of action for this patient?

- 1- Contact the Police
- 2- Contact tracing of sexual partners
- 3- Informal enquiry to the nursing home
- 4- Seek advice from the MDU
- 5- Treat the patient and discharge back to the nursing home

Answer & Comments

Answer: 4- Seek advice from the MDU

These ethical questions can be quite tough to answer with accuracy. This question specifically relates to elder abuse - in this case potential elder sexual abuse. The scenario is one that is often played out in the press of a care worker that sexually abuses elderly patients in his/her care. However, you are given very little information here and what you would do is undoubtedly treat the patient and establish how the patient contracted gonorrhoea. The question states that she has a profound dementia suggesting that abuse has occurred rather than consensual sex. However, you need to establish the facts and you have a personal duty of care to the patient and next of kin to establish these before automatically contacting the police. It is likely that the police will need to be called but first it would be worth talking things through and obtaining advice from the MDU. The advice may entail establishing the set-up at the nursing home, discussing with the next of kin, social services if a social worker has been involved, finely detailing any injuries that may be present on examination and then possibly contacting the Police.

[Q: 1010] OnExamination - Infectious disease

Which of the following is true of the T cell

response to antigen?

- 1- A process of affinity maturation of the T cell receptor occurs.
- 2- Intact antigen is presented in association with self MHC molecules.
- 3- Co-operation with other cell types is required for T cell recognition of antigen.
- 4- gamma/delta + T cells respond to antigen presented in association with MHC class II molecules.
- 5- Interactions of the TcR with an appropriate Ag/MHC complex activates a resting T cell.

Answer & Comments

Answer: 3- Co-operation with other cell types is required for T cell recognition of antigen.

a) Affinity maturation in an ongoing immune response is a feature of the antibody response. There is no evidence that a similar process occurs in the T cell response.

b) MHC molecules present short antigen-derived peptides, not the intact antigen.

c) T cells recognise antigen only when presented by (self) MHC molecules on an antigen presenting cell.

d) MHC class II molecules present antigen to CD4+, alpha/beta+ T cells. It is still not clear how gamma/delta+ T cells recognise antigen, however most gamma/delta+ T cells do not appear to be restricted by (self) MHC molecules.

e) Additional 'costimulatory' signals are required to activate a resting T cell. Interaction of the TcR of a resting T cell with an appropriate Ag/MHC complex in the absence of costimulatory signals may lead to the induction of anergy.

[Q: 1011] OnExamination - Infectious disease

A 22-year-old female student attended

Casualty complaining of fever and rigors for two days. She had returned from a sabbatical in Africa six weeks previously. She was febrile (39.9°C) and a mild petechial rash was also noted. Laboratory investigations showed.

Hb 10.1 g/dL (11.5-16.5)

WBC $3.0 \times 10^9/L$ (4-11)

Platelets $115 \times 10^9/L$ (150-400)

Prothrombin time Normal

What is the most likely diagnosis?

- 1- Acute HIV infection (seroconversion illness)
- 2- Cytomegalovirus infection
- 3- Dengue fever
- 4- Plasmodium falciparum malaria
- 5- Typhoid fever

Answer & Comments

Answer: 1- Acute HIV infection (seroconversion illness)

A difficult question that partly hinges on the incubation times of these illness. The incubation time is too long for dengue, typhoid and falciparum malaria. The presentation is not typical of CMV. Acute HIV presents 2 weeks - 3 months after exposure to the virus; the illness typically consists of fever, arthritis, rash and lymphadenopathy. The presentation given here is not characteristic of acute HIV, but is the most reasonable of the options listed.

[Q: 1012] OnExamination - Infectious disease

Which one of the following statements concerning T-lymphocytes is correct?

- 1- Are the primary host response in bacterial infection
- 2- Compose the majority of lymphocytes in plasma
- 3- Are infected by Epstein-Barr virus in infectious mononucleosis

4- produce IgG

5- T cell lymphoma has a better prognosis than B cell lymphoma

Answer & Comments

Answer: 2- Compose the majority of lymphocytes in plasma

The primary host response to bacterial infections is dependent on mononuclear phagocytes and neutrophils. T-lymphocytes are involved in cell-mediated acquired immune responses, whereas B-lymphocytes are involved in humoral immunity and produce immunoglobulins. T lymphocytes compose the majority of circulating lymphocytes in plasma. Epstein-Barr virus infects B-lymphocytes and squamous epithelial cells of the oropharynx. The virus can transform B cells and epithelial cells to produce Burkitt's lymphoma, a subset of Hodgkin's lymphoma, nasopharyngeal carcinoma and oral hairy leukoplakia. T cell lymphoma makes up about 10-20% of non-Hodgkin's lymphomas and has a worse prognosis than B cell lymphoma.

[Q: 1013] OnExamination - Infectious disease

A 15-year-old female is a close contact of a student who has developed meningitis C. The last contact she had with her friend was two days ago when her friend developed headache. She has not received any previous vaccination for meningitis.

What is the most appropriate action for this girl?

- 1- No treatment is required and the girl can be reassured
- 2- Treat with rifampicin only
- 3- She should receive the meningococcal A and C vaccination only
- 4- She should receive meningococcal immunoglobulin only

- 5- She should receive the meningococcal A and C vaccination plus rifampicin

Answer & Comments

Answer: 5- She should receive the meningococcal A and C vaccination plus rifampicin

This girl runs a reasonably high risk of developing meningitis and should receive Meningitis C vaccination together with rifampicin. Antibiotics used for chemoprophylaxis are rifampicin, minocycline, spiramycin, ciprofloxacin and ceftriaxone.

More [here](http://www.hpa.org.uk/infections/topics_az/meningo/guidelines.htm)
http://www.hpa.org.uk/infections/topics_az/meningo/guidelines.htm

[Q: 1014] OnExamination - Infectious disease

Which of the following statements regarding Japanese Encephalitis is most true?

- 1- It is a DNA virus
- 2- Previous exposure to a flavivirus predisposes to increased risk of death on infection with Japanese Encephalitis
- 3- Transplacental transmission occurs
- 4- It is only recognised in travellers who have spent prolonged periods in endemic areas
- 5- Is endemic in East Africa

Answer & Comments

Answer: 3- Transplacental transmission occurs

Japanese encephalitis is an RNA virus which is endemic in India, East Asia, Malaysia and the Philippines. Previous infection by a pathogen which is a member of the flavivirus family seems to protect against serious disease or death when infection occurs with another member of the flavivirus family. For instance previous exposure to Dengue lowers the risk of death when infected by Japanese Encephalitis. Infection with Japanese

Encephalitis has been reported in travellers who have spent only short periods in endemic areas, and transplacental transmission can occur. An immunisation is available for travellers.

[Q: 1015] OnExamination - Infectious disease

Four members of a football team develop diarrhoea due to Salmonella enteritidis.

Eating which food was the most likely source of the infection?

- 1- chicken at a fast food outlet 20 hours earlier
- 2- fried rice at a takeaway 4 hours earlier
- 3- raw eggs in milk 6 hours earlier
- 4- raw oysters at a hotel 24 hours earlier
- 5- soft cheeses 48 hours earlier

Answer & Comments

Answer: 1- chicken at a fast food outlet 20 hours earlier

The incubation time for Salmonella enteritidis is 12 - 48 hours and the likely sources are poultry and eggs. Raw oysters are associated with infections such as the Norwalk agent.

[Q: 1016] OnExamination - Infectious disease

A 35-year-old man is seen 6 months after a cadaveric renal allograft. He receives azathioprine and prednisolone. He has felt generally unwell for the past week with a pyrexia of 38.6°C, anorexia and a cough productive of thick green sputum. Chest x-ray reveals a left lower lobe nodule of approximately 5cm diameter with central cavitation. Analysis of the sputum reveals long, crooked, branching and beaded gram-positive filaments.

Which of the following antimicrobials is the most appropriate initial therapy for this patient?

- 1- Ceftazidime
- 2- Co-amoxiclav
- 3- Co-trimoxazole
- 4- Erythromycin
- 5- Rifampicin and Isoniazid

Answer & Comments

Answer: 3- Co-trimoxazole

The likely diagnosis is Nocardiosis. Nocardia are aerobic, Gram-positive branching filamentous bacteria which often appear beaded on staining. Nocardiosis can be diagnosed rapidly by examination of sputum or pus with the Gram stain and a modified acid-fast stain. Pneumonia is typically found in the immunocompromised as in this case and may be a single lesion or extensive pneumonic consolidation. The drug of choice is trimethoprim-sulfamethoxazole.

[Q: 1017] OnExamination - Infectious disease

A 27-year-old man presents with fever, urethritis and arthralgia. He is found to have a swollen ankle with a pustular rash on the dorsal aspect of his foot.

What is the most likely diagnosis?

- 1- Gonococcal sepsis
- 2- Lyme disease
- 3- Reiter's syndrome
- 4- Staphylococcal arthritis
- 5- Tuberculous arthritis

Answer & Comments

Answer: 1- Gonococcal sepsis

The most likely cause for this acute presentation is gonococcal septicaemia - with

a pustular rash on the dorsum of his foot, fever, urethritis and oligoarthritis. Reiter's is associated with an acute infection - urethritis/diarrhoea and later the development of an arthritis.

[Q: 1018] OnExamination - Infectious disease

A 28-year-old man had been treated for pulmonary tuberculosis with rifampicin, isoniazid, pyrazinamide and ethambutol for four weeks. Pre-treatment liver function tests were normal but his most recent investigations revealed:

serum total bilirubin 98 micromol/l (0-18)
 serum alanine aminotransferase 620u/l (5-45)
 serum aspartate aminotransferase 450 u/l (5-45)
 serum alkaline phosphatase 720 u/l (40-110)

Which one of the following is the most appropriate next step?

- 1- Stop all treatment
- 2- Stop ethambutol
- 3- Stop isoniazid
- 4- Stop pyrazinamide
- 5- Stop rifampicin

Answer & Comments

Answer: 1- Stop all treatment

All tuberculosis patients should have pretreatment LFT, should be supervised by a chest physician and should be informed of possible side-effects of treatment. If there is no pre-existing liver disease, LFTs are only repeated (and treatment stopped) if fever, malaise, vomiting, jaundice or unexplained deterioration occurs during treatment. Regular LFT should be performed in patients with previously known chronic liver disease. If AST/ALT levels rise by 5 times normal/bilirubin level rises, then

rifampicin/isoniazid/pyrazinamide should be stopped.

If the patient is not unwell and/or has non-infectious TB, no treatment until LFT returns to normal.

If clinically unwell or sputum smear positive within 2 weeks of starting treatment, consider streptomycin and ethambutol until LFT returns to normal.

Once LFT back to normal, challenge dosages can be reintroduced sequentially in order of isoniazid, rifampicin and pyrazinamide with daily monitoring of patient's condition and LFT.

If further reaction, offending drug excluded and a suitable alternative regimen used.

[Q: 1019] OnExamination - Infectious disease

A 57-year-old woman develops a blistering rash around the midriff and is diagnosed with herpes zoster. She is treated with acyclovir.

Activation of acyclovir by which of the following is responsible for its action?

- 1- Integrase
- 2- Polymerase
- 3- Protease
- 4- Reverse transcriptase
- 5- Thymidine kinase

Answer & Comments

Answer: 5- Thymidine kinase

This is a variation on the acyclovir theme. Aciclovir acts through inhibition of viral DNA polymerase but it is a pro-hormone and first requires phosphorylation by Thymidine Kinase.

[Q: 1020] OnExamination - Infectious disease

*Which of the following concerning *Corynebacterium diphtheriae* is correct?*

- 1- Causes skin infection
- 2- Infection is often complicated by myocardial fibrosis after recovery from severe infection
- 3- Is most unlikely to cause infection in an individual with a positive Schick test
- 4- Mitis strain is generally more virulent than the intermedius strain
- 5- Toxin is better absorbed through the nasal than the pharyngeal mucosa

Answer & Comments

Answer: 1- Causes skin infection

Corynebacterium diphtheriae is a gram positive, non-spore forming, pleomorphic bacteria that is also a facultative anaerobe. *Corynebacterium diphtheriae* causes Diphtheria. Typically diphtheria attacks the respiratory system, but may also affect the skin, conjunctiva and external genitalia. Signs and symptoms include sore throat, fever, and swelling of lymph nodes in the neck and general malaise. As the disease progresses Diphtheria toxin is secreted. This destroys the membrane surface of the affected areas and replaces them with a grayish tough leathery "Pseudomembrane" made of dead tissue, leukocytes and bacteria. Toxin could also affect the heart, nerves and other organs in the body causing Heart failure, nerve damage or suffocation. Toxin can be neutralized by the immune serum produced by the host cells. Diphtheria is transmitted from person to person. Human beings are the main reservoir.

[Q: 1021] OnExamination - Infectious disease

A 52-year-old man presented to the Accident & Emergency unit with a two day history of

increasing breathlessness, productive cough and fever. He was previously fit and well with no past history of note. He was not a cigarette smoker. On examination he was febrile, temperature was 38.5°, pulse rate 100/minute and regular, blood pressure 120/80 mmHg and respiratory rate of 25 breaths/minute. Investigations:

Hb 15.0 g/dL

WBC $18.5 \times 10^9/L$

Platelets $350 \times 10^9/L$

Serum sodium 137 mmol/L

Serum potassium 4.5 mmol/L

Serum urea 5.1 mmol/L

Serum creatinine 110 $\mu\text{mol/L}$

paO₂ (arterial blood, on air) 9.0 kPa

Chest x-ray showed right middle lobe consolidation

What is the most appropriate choice of antibiotics?

- 1- Amoxicillin
- 2- Amoxicillin plus Erythromycin
- 3- Ceftriaxone
- 4- Ciprofloxacin
- 5- Co-Amoxiclav

Answer & Comments

Answer: 1- Amoxicillin

While in practice it is perfectly acceptable to give such a patient both amoxicillin and clarithromycin (B), the question tests deeper knowledge of the British Thoracic Society guidelines on the management of community-acquired pneumonia. Given this patient's symptoms, signs and results, he falls in to the 'good prognosis' category (see BTS guidelines). Adverse prognostic features include: ?Age >50 years ?Coexisting disease ?Confusion (MMS <8) ?Respiratory rate >30 ?Systolic BP <90 and/or diastolic <60 ?Raised serum urea (>7 mmol/L) ?Hypoxia (PaO₂ <

8kPa) ?Bilateral/multilobar consolidation on CXR

Essentially, he appears relatively well and could be managed at home. According to BTS guidelines, such patients could be treated with antibiotic monotherapy ?so amoxicillin alone would suffice

British Thoracic Society guidelines for the management of community-acquired pneumonia can be downloaded from:

http://www.brit-thoracic.org.uk/public_content.asp?pageid=7&catid=36&subcatid=144

[Q: 1022] OnExamination - Infectious disease

Which of the following is true of BCG vaccination?

- 1- is contraindicated in neonates
- 2- is a killed polysaccharide antigen vaccine
- 3- should be given to all children who have a strongly positive tuberculin test
- 4- is presently routinely offered in the UK at age 16 years
- 5- Provides protection against leprosy

Answer & Comments

Answer: 5- Provides protection against leprosy

a - BCG vaccine may given to newborns at high risk of exposure.

b - The BCG vaccine is an attenuated strain - it provides approximately 70% protection.

c - It should NOT be given to these children. A low reactivity Heaf test (grade 0 - 1) should be documented before administration.

d - BCG is given at Comprehensive school entry (age 11 - 13).

e - It has also found a use in stimulating the immune system for the treatment of some cancers.

[Q: 1023] OnExamination -
Infectious disease

You are an occupational health physician and have been asked by an anxious employee about contraindications to pertussis immunisation.

Which of the following is a contraindication?

- 1- Eczema
- 2- Cow's milk protein intolerance.
- 3- Fever to 39.5 C following the first dose.
- 4- Redness of >2.5cm at the injection site after the first dose.
- 5- Hydrocephalus

Answer & Comments

Answer: 3- Fever to 39.5 C following the first dose.

Answer: 3) Fever to 39.5 C following the first dose.

True contraindications to pertussis immunisation include:

- " Acute illness - until recovered.
 - " Previous reaction to pertussis:
 - o Local: an extensive area of redness and swelling which becomes indurated, involving most of the anterolateral surface of the thigh or a major part of the circumference of the upper arm.
 - o General: fever equal to or more than 39.5 C within 48 hours of vaccine, anaphylaxis, bronchospasm, laryngeal oedema, generalised collapse, prolonged hyporesponsiveness, prolonged inconsolable or high-pitched screaming of >4 hours, convulsions or encephalopathy occurring within 72 hours.
- A personal family history of allergy is not a contraindication, nor are stable neurological conditions such as cerebral palsy or spina bifida. In patients who have had a previous reaction, immunisations should be completed

with DT vaccine, and acellular vaccine considered.

[Q: 1024] OnExamination -
Infectious disease

A 15-year-old girl presents to casualty with mild gastrointestinal upset. She had recently returned from holiday where she had been swimming in the hotel pool.

What is the most likely causative organism?

- 1- Campylobacter jejuni
- 2- Cryptosporidium parvum
- 3- Salmonella enteridis
- 4- Shigella flexneri
- 5- Staphylococcus aureus

Answer & Comments

Answer: 2- Cryptosporidium parvum

Human cryptosporidiosis causes self-limited diarrhoeal illness in healthy individuals, mostly children; and severe prolonged diarrhea in patients with AIDS. Transmission is via human-to-human fecal-oral contamination. Animals are the major reservoir and outbreaks have been associated with water supplies and public swimming pools.

[Q: 1025] OnExamination -
Infectious disease

A patient is planning to travel through the southern states of America, but is worried about West Nile Virus.

Which of the following statements regarding West Nile Virus is correct?

- 1- Infection is non-fatal
- 2- Is a member of the arbovirus family
- 3- Transplacental transmission does not occur
- 4- May be associated with Poliomyelitis-like paralysis

- 5- Treatment with interferon is effective in West Nile Virus encephalitis

Answer & Comments

Answer: 4- May be associated with Poliomyelitis-like paralysis

Neurological manifestations of West Nile Virus include a poliomyelitis-like paralysis, seizures and a Parkinsonian movement disorder. West Nile Virus is a Flavivirus of the Japanese Encephalitis family, and transplacental transmission has been reported. In 2003, there were 276 deaths attributed to West Nile Virus. Interestingly, West Nile Virus is endemic in the avian population. The deaths of large numbers of birds in an area may thus herald an imminent epidemic of West Nile Virus.

[Q: 1026] OnExamination - Infectious disease

A 30-year-old man developed a febrile illness three days after returning from a holiday in Thailand. He was admitted complaining of severe myalgia. On examination he was febrile (39°C) with a diffuse macular rash on the trunk. There was no lymphadenopathy. Investigations revealed:

Haemoglobin 15.1 g/dL (13.0-18.0)

White cell count $7.5 \times 10^9/L$ (4-11)

Platelet count $105 \times 10^9/L$ (150-400)

Serum total bilirubin 18 mmol/L (1-22)

Serum alanine aminotransferase 120 U/L (5-35)

What is the most likely diagnosis?

- 1- Acute HIV infection (seroconversion illness)
- 2- Dengue fever
- 3- Hepatitis E
- 4- Secondary syphilis
- 5- Typhoid

Answer & Comments

Answer: 2- Dengue fever

The symptoms are most consistent with dengue fever. While acute retroviral syndrome (acute HIV) is associated with a widespread macular rash, it is also usually associated with pharyngitis and generalised lymphadenopathy. Hepatitis E presents in a similar manner to hepatitis A, i.e. as an acute febrile illness with jaundice. The history is too acute for secondary syphilis, which is not typically associated with myalgia. Typhoid fever is usually a diarrhoeal illness associated with subtle 'rose spots' on the abdomen.

Dengue fever is caused by an arthropod-borne flavivirus. The disease has an incubation period of approximately 7 days, followed by headaches and retro-orbital pain. Symptoms evolve rapidly and severe musculoskeletal pain is a prominent feature, with a maculopapular rash.

[Q: 1027] OnExamination - Infectious disease

A 35-year-old man returned from a two-week holiday complaining of pain in the loins and painful swollen knees. On examination he was afebrile and had significant bilateral knee effusions. Mild penile erythema was also noted. Laboratory investigations showed:

Hb 15.6 g/dL

WBC $16.2 \times 10^9/L$

Neutrophils $14.1 \times 10^9/L$

ESR 65 mm/h

Rheumatoid factor 10 IU/L

Urinalysis No cells, casts or bacteria seen

What is the most likely diagnosis?

- 1- Arthritis due to *Neisseria gonorrhoeae* infection
- 2- Lymphogranuloma venereum
- 3- Reactive arthritis

- 4- Reitter's syndrome
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 1- Arthritis due to Neisseria gonorrhoeae infection

Gonococcal arthritis typically affects the knees and is the likeliest diagnosis in this scenario.

[Q: 1028] OnExamination - Infectious disease

A 17-year-old man presented to casualty complaining of difficulty breathing. He had been brought to hospital by ambulance, having collapsed shortly after being stung on the hand by a bee. On examination, his blood pressure was 80/40 mmHg, and facial swelling was noted.

Which one of the following investigations is most likely to confirm the nature of the reaction?

- 1- Haemolytic complement (CH50) level
- 2- Plasma tryptase activity
- 3- Serum complement C3 level
- 4- Serum total IgE level
- 5- Serum venom-specific IgE level

Answer & Comments

Answer: 2- Plasma tryptase activity

Type I hypersensitivity, also known as immediate or anaphylactic hypersensitivity, usually takes 15 - 30 minutes from the time of exposure to the antigen. The reaction may cause a range of symptoms from minor inconvenience to death. The reaction involves preferential production of IgE, in response to certain antigens, which in turn initiates a sequence of events leading to the release various pharmacologically active substances that are responsible for the clinical features. Diagnostic tests include skin tests,

measurement of total IgE and specific IgE antibodies against the suspected allergens. However, this question asks which of the following tests would provide confirmatory information and that would be Tryptase.

Tryptase is a neutral protease stored in mast cell secretory granules that is secreted by human mast cells. Levels in normal blood are undetectable (< 1 ng/ml). Elevated serum levels demonstrate that mast cell activation with mediator release has occurred whether triggered by IgE-mediated anaphylaxis or non-IgE-mediated anaphylactoid reactions. The greater the severity of anaphylaxis, the more likely that serum -tryptase levels will be elevated.

[Q: 1029] OnExamination - Infectious disease

Which of the following forms of encephalitis is caused by a neuroimmunological response?

- 1- Herpes simplex
- 2- Measles
- 3- HIV infection
- 4- Enteroviruses
- 5- Cytomegalovirus

Answer & Comments

Answer: 2- Measles

Encephalitis may be caused by:

- " Direct invasion by a neurotoxic virus (encephalitis).
- " Post-infectious encephalopathy: delayed brain swelling because of an immunological response to the antigen.
- " Slow virus infection, e.g. HIV or SSPE.

Direct infection is most commonly caused by enteroviruses, HSV 1 and 2, varicella, CMV, and EBV. It is also occasionally caused by respiratory viruses, HHV6, rubella or mumps.

A post-infectious illness may also be caused by measles or varicella zoster (cerebellar ataxia).

[Q: 1030] OnExamination - Infectious disease

Two strains of Escherichia coli are isolated and both are resistant to ampicillin. Strain A retains its resistance to ampicillin when grown from multiple generations in the absence of ampicillin. However strain B loses its resistance when grown in the absence of ampicillin.

Which of the following best explains the loss of antibiotic resistance in strain B?

- 1- Changes in the bacterial DNA gyrase
- 2- Downregulation of the resistance gene
- 3- Loss of a plasmid containing the resistance gene
- 4- Mutations in the resistance gene
- 5- Transposition of another sequence into the resistance gene

Answer & Comments

Answer: 3- Loss of a plasmid containing the resistance gene

Bacteria develop resistance to antibiotics by gaining genes that encode for particular proteins that offer protection to the organism. Sometimes this is by mutation and other times the gene may be acquired from another bacterial species. The genes are usually found in plasmids - circular segments of DNA separate from the bacterial chromosome. Plasmids can easily spread from one bacteria to another - a sort of resistance package that bacteria can share.

[Q: 1031] OnExamination - Infectious disease

Which of the following statements is true about immunological reactions?

- 1- Serum sickness is caused by a type II reaction.
- 2- Grave's Disease is caused by a type IV reaction.
- 3- Angio-neurotic oedema is the most severe form of type I reaction.
- 4- Urticaria usually responds to Cimetidine.
- 5- Deficiencies in the terminal components of complement increase the risk of meningococcal disease.

Answer & Comments

Answer: 5- Deficiencies in the terminal components of complement increase the risk of meningococcal disease.

Answer: 5) Deficiencies in the terminal components of complement increase the risk of meningococcal disease.

Serum sickness is due to circulating antibody-antigen complexes (Type III). Grave's Disease is due to stimulating antibody (Type V). The most severe variety of Type I reaction is anaphylaxis, with angio-oedema an intermediate reaction associated with wheeze and swelling of the lips and severe urticaria. These reactions are mediated by histamine 1 receptor stimulation. Congenital C1 inhibitor deficiency is also caused hereditary angio-oedema. Deficiencies in C1r, s, and 2-4 result in vasculitides; while deficiencies in C2, 3 and 5-8 are associated with an increased risk of septicaemia.

[Q: 1032] OnExamination - Infectious disease

A 42-year-old HIV-seropositive man presents to Casualty with a two-week history global headache. His partner says that he has become increasingly confused and disorientated. The patient's latest CD4 count, taken three weeks ago, was 50 cells/mm³. He had chosen not to take antiretroviral therapy, but was taking co-trimoxazole as prophylaxis

against *Pneumocystis carinii* pneumonia. On examination he had mild weakness of his left arm and leg in all muscle groups and a right homonymous hemianopia. Fundoscopy was normal with no evidence of papilloedema. A CT scan of his brain showed several areas of low attenuation in both cerebral hemispheres, but there was no enhancement with contrast and no mass effect.

What is the most likely diagnosis?

- 1- Cerebral lymphoma
- 2- Cerebral toxoplasmosis
- 3- HIV encephalopathy
- 4- Neurosyphilis
- 5- Progressive multifocal leukoencephalopathy

Answer & Comments

Answer: 5- Progressive multifocal leukoencephalopathy

The most likely diagnosis is Progressive multifocal leukoencephalopathy (PML), a demyelinating disease seen in advanced HIV/AIDS and caused by the JC virus. Cerebral lymphoma and cerebral toxoplasmosis are often associated with mass effect on CT brain scanning. In CNS lymphoma there is usually a solitary lesion. Cerebral toxoplasmosis is frequently associated with multiple lesions that show ring enhancement with iv contrast. HIV encephalopathy may be associated with confusion, but is not associated with this CT appearance. This is not a typical presentation of neurosyphilis in any of its forms.

[Q: 1033] OnExamination - Infectious disease

Chronic liver disease is NOT a complication of

- 1- Haemosiderosis
- 2- Hepatitis C
- 3- alpha1 antitrypsin deficiency
- 4- cystic fibrosis

- 5- haemochromatosis

Answer & Comments

Answer: 1- Haemosiderosis

50% of hepatitis C infections leads to chronic liver disease (treat with interferon-a). Liver disease from chronic cholestasis occurs in cystic fibrosis. Alpha1 antitrypsin deficiency causes both cirrhosis and emphysema. Haemochromatosis is autosomal recessive and is characterized by excessive iron deposition in various organs causing organ failure (diabetes, heart failure, chronic liver disease, hypogonadism, skin pigmentation and arthritis). Haemosiderosis usually arises due to parenteral iron overload e.g. in patients with aplastic anaemia after multiple transfusions. It is not commonly associated with cirrhosis. If cirrhosis does develop as a result of massive iron overload the condition is known as secondary haemochromatosis.

[Q: 1034] OnExamination - Infectious disease

An 35-year-old man presented with high fever, headache and mild jaundice on returning from a holiday in Spain. The group of 20 had travelled together visiting forestry on the hills with fishing trips in mountain streams.

Which of the following organisms is most likely to be responsible for their illness?

- 1- Borelia Burgdorferi
- 2- Legionella pneumophila
- 3- Leptospira icterohaemorrhagica
- 4- Mycoplasma pneumoniae
- 5- Pneumococcus

Answer & Comments

Answer: 3- Leptospira icterohaemorrhagica

Leptospirosis, or Weil's disease, is transmitted to man by animals, including rodents (rat urine and faeces), skunks, foxes, cattle, dogs.

The disease is characterized by jaundice, fever, oliguria, headache, myalgia, haemorrhagic tendencies with purpura or petechiae, and enlargement of liver and spleen.

[Q: 1035] OnExamination - Infectious disease

Which of the following is true of tetanus?

- 1- failure to culture *Clostridium tetani* from the wound would make the diagnosis doubtful
- 2- infection confers lifelong immunity
- 3- there is a characteristic EEG
- 4- *Clostridium*-specific intravenous immunoglobulin is of no benefit once spasm has started
- 5- cephalic tetanus causes severe dysphagia

Answer & Comments

Answer: 5- cephalic tetanus causes severe dysphagia

a-absence of a wound does not exclude tetanus. b-patients need to be actively immunized after recovery. c-The toxin tetanospasmin doesn't cross the blood brain barrier, it diffuses through the blood to bind to receptors containing gangliosides on the neuronal membranes of presynaptic nerve terminals in muscles. The toxin does reach the brain by axonal transport. d-it is ineffective once the toxin is attached to nervous tissue but may prevent progression. e-Cephalic meaning involving the cranial nerves usually from a wound on the head and neck. May be confused with rabies but hydrophobia never occurs. (OTM, 3e, 7.11.20)

[Q: 1036] OnExamination - Infectious disease

Regarding diphtheria which of the following statements is correct?

- 1- It is predominantly spread from cutaneous lesions.
- 2- It is characterised by an inflammatory exudate forming a greyish membrane on the buccal mucosa.
- 3- It produces a toxin which affects the myocardium, nervous and adrenal tissues.
- 4- 3 doses of toxoid provides 75% protection.
- 5- About 50 cases per year are seen in the UK.

Answer & Comments

Answer: 3- It produces a toxin which affects the myocardium, nervous and adrenal tissues.

Diphtheria is spread by droplets, through contact with soiled articles (fomites), and, in areas of poor hygiene, from cutaneous spread. The inflammatory exudate forms a greyish membrane on the tonsils and respiratory tract which may cause respiratory obstruction. Incubation is between 2 and 5 days, and patients may be infectious for 4 weeks. The toxin affects the myocardium, nervous and adrenal tissues. The immunisation has been tremendously successful, and most cases seen in the UK are imported from the Indian subcontinent or Africa. Recently, there has been a worrying epidemic of diphtheria in Russia and the newly independent states of the former Soviet Union. In 1995, 52,000 cases and 1,700 deaths were reported.

[Q: 1037] OnExamination - Infectious disease

A 23-year-old female presents 16 weeks into her pregnancy with a vaginal discharge. Further investigation confirms infection with *Chlamydia trachomatis*.

Which of the following is the most appropriate treatment for this patient?

- 1- Azithromycin
- 2- Ciprofloxacin
- 3- Co-trimoxazole

- 4- Doxycycline
5- Metronidazole

Answer & Comments

Answer: 1- Azithromycin

C. Trachomatis infection is common in pregnancy and is associated with adverse fetal outcome including spontaneous miscarriage, premature rupture of membranes and IUGR. Appropriate treatment is with macrolides such as erythromycin or azithromycin. Both doxycycline and ciprofloxacin are contraindicated in pregnancy.

[Q: 1038] OnExamination - Infectious disease

Which of the following is true of anthrax?

- 1- It is caused by an aerobic, gram negative rod.
- 2- It causes trivial disease in the host herbivore population.
- 3- Gastrointestinal anthrax is the most usual form of disease in humans.
- 4- Eshars are usually painless.
- 5- Sputum culture has a high yield in inhalational anthrax.

Answer & Comments

Answer: 4- Eshars are usually painless.

Answer: 4) Eshars are usually painless.

Anthrax will be a particularly topical question in the exam. It is caused by the gram positive, aerobic, non-motile *Bacillus Anthracis*. It produces serious disease in the herbivore host and carnivores acquire disease from either consuming the spores from the dead animal or by contact. In humans, cutaneous disease is most common and a painless, black, indurated eschar frequently forms. Mortality from cutaneous disease is 20% if untreated whereas

inhalational anthrax may have a mortality of 90% if untreated. Inhalational anthrax is associated with a poor yield from sputum culture with the greatest yield from blood culture.

[Q: 1039] OnExamination - Infectious disease

A 19-year-old man returned to the UK two weeks after working in a refugee camp in sub-Saharan Africa. On examination he was febrile, dyspnoeic and widespread inspiratory crackles were present. He had an extensive maculo-papular rash, conjunctivitis, generalized stomatitis and some bluish-grey spots on the buccal mucosa.

What is the most likely diagnosis?

- 1- Epidemic typhus
- 2- Epstein Barr virus infection
- 3- Leptospirosis
- 4- Measles
- 5- Parvovirus infection

Answer & Comments

Answer: 4- Measles

Although seldom seen in countries in which a vaccine is available, measles is a major health problem in refugee camps in Africa. The clinical picture described is characteristic. The major complications of measles involve the respiratory tract and CNS. Pneumonia may be caused by the virus itself, or through bacterial superinfection.

[Q: 1040] OnExamination - Infectious disease

A 47-year-old woman presents with high fever, rigors and myalgia. Nasal aspirate is positive for influenza virions.

Which of the following is true of her B-cell response?

- 1- The antibody response to the virus does not require T-cell help
- 2- Her B-cells express immunoglobulin on their surface
- 3- Deficiency of either CD40 or CD40L still allows an IgG response
- 4- Affinity maturation takes place in the blood stream
- 5- Memory cells are not formed as repeated infections with influenza often occur

Answer & Comments

Answer: 2- Her B-cells express immunoglobulin on their surface

B-cells usually require T-cell help for full activation. B-cells activated in the primary immune response initially produce IgM. With continuing T-cell help, B-cells then undergo heavy chain class switching and enter germinal centres in secondary lymphoid organs. The germinal centres are the sites of immunoglobulin affinity maturation and memory B-cell formation. Various factors including the nature of T-cell help, antigen exposure site and cytokine profile, determine the isotype of heavy chain produced. CD40 and CD40L are required for co-stimulation by T-cells. Deficiency of either CD40 or CD40L impairs class switching. Certain antigens can activate B-cells in the absence of T-cell help - thymus independent antigen. T-cell independent B-cell responses are mainly to carbohydrate antigen e.g. pneumococcal polysaccharide. These antigens are not processed and presented in association with MHC molecules, and therefore cannot activate T-helper cells. Most TI antigens have highly repetitive epitopes (e.g. LPS/endotoxin), which are able to cross link B-cell surface immunoglobulin and activate these cells. Some T-cell independent antigens can cause proliferation of B-cells regardless of their specificity - polyclonal B-cell activation. B cell responses to T-independent antigens consist mainly of IgM antibodies of low affinity

without the production of memory cells. The influenza virus will activate T- and B-cells, and result in memory cell production. Genetic mutation in the virus is responsible for immune evasion and repeated infections.

[Q: 1041] OnExamination - Infectious disease

A 16-year-old boy presented with fever, headache and neck stiffness for 24 hours. He had an identical illness requiring admission to hospital for 1 year previously.

Cerebrospinal fluid analysis shows White cells of 400/ml with a 90% neutrophilia and gram stain revealed scanty gram-negative diplococci.

Which component of the immune system is likely to be defective?

- 1- B lymphocytes
- 2- Complement pathway
- 3- Immunoglobulin
- 4- Neutrophils
- 5- T lymphocytes

Answer & Comments

Answer: 2- Complement pathway

This young man has a recurrent meningococcal meningitis, and deficiencies of complement C5-9 predispose to Neisseria infections (complement deficiencies). One must recognise that the diplococci seen on microscopy are those of Neisseria meningitidis.

[Q: 1042] OnExamination - Infectious disease

A 42 year-old restauranter who has been HIV positive for 8 years presents with progressive shortness of breath on exercise. The chest X-ray is normal except for prominent pulmonary arteries. Pulse oximetry demonstrates that he desaturates on exercise.

Which is the most likely diagnosis?

- 1- Pneumocystis carinii pneumonia
- 2- Primary pulmonary hypertension
- 3- Intracardiac shunt across an atrial septal defect
- 4- Pulmonary embolic disease
- 5- Anaemia

Answer & Comments

Answer: 1- Pneumocystis carinii pneumonia

The history of dyspnoea and exercise induced dyspnoea in a HIV positive male with no signs on the chest X-ray and little other data would suggest PCP until proved otherwise. Pulmonary hypertension is another possibility and occurs in HIV patients, but the most likely choice would be PCP.

[Q: 1043] OnExamination - Infectious disease

A 48-year-old man with a known history of chronic alcohol abuse presented with a three-day history of fevers, night sweats and a cough productive of purulent sputum. There was no past history of respiratory disease.

On examination he was febrile (39.1°C). Percussion note was dull over the right apex and there was bronchial breathing in this area on auscultation. The chest x-ray showed right upper lobar consolidation.

Other investigations revealed

WBC 23 x 10⁹/L

Neutrophils 18.3 x 10⁹/L

What is the most likely diagnosis?

- 1- Aspiration pneumonia
- 2- Klebsiella pneumonia
- 3- Legionella pneumonia
- 4- Mycoplasma pneumonia
- 5- Primary tuberculosis

Answer & Comments

Answer: 2- Klebsiella pneumonia

Community-acquired Klebsiella pneumonia is a disease of debilitated middle-aged and older men with alcoholism. Mortality rates are as high as 50% regardless of treatment. Klebsiella pneumonia characteristically affects one of the upper lobes of the lung, although infection of the lower lobes is not uncommon. There is an increased tendency toward abscess formation. Aspiration pneumonia typically affects in right lower lobe in persons with impaired swallowing. Legionnaires' disease is associated with contaminated air conditioning and water delivery systems. Mycoplasma pneumoniae infections have an insidious onset with malaise, myalgia, sore throat and headache. Cough is characteristically dry. CXR changes are usually patchy and involve the lower or middle lobes.

[Q: 1044] OnExamination - Infectious disease

A 82-year-old lady is admitted from her nursing home with headache, photophobia and neck stiffness. Her temperature is 39.0°C, pulse rate 115 beats/min. There is no skin rash or focal neurological signs and her Glasgow coma scale is 15/15. A CT scan shows no contraindication to lumbar puncture. CSF is obtained and Gram stain shows Gram negative cocc-bacilli, subsequent culture confirms a Haemophilus influenzae meningitis.

What chemoprophylaxis should be offered to the nurses at her home?

- 1- Azithromycin
- 2- Ceftriaxone
- 3- Ciprofloxacin
- 4- no chemoprophylaxis required
- 5- Rifampicin

Answer & Comments

Answer: 5- Rifampicin

Close contacts of *Haemophilus influenzae* meningitis should receive rifampicin; children under 2 years should be vaccinated.

[Q: 1045] OnExamination - Infectious disease

A 26-year-old man with a history of alcohol and drug abuse was admitted with a 14 day history of fever, cough and fatigue. He was emaciated. His temperature was 39.4°C. Cervical and axillary lymphadenopathy were present. Chest X-ray revealed bilateral areas of pulmonary shadowing.

Which of the following is the most likely diagnosis?

- 1- alcoholic cardiomyopathy
- 2- pneumococcal pneumonia
- 3- pneumocystis pneumonia
- 4- pulmonary tuberculosis
- 5- tricuspid endocarditis

Answer & Comments

Answer: 3- pneumocystis pneumonia

Pneumocystis carinii is the most common opportunistic infection in AIDS. This patient is at risk of HIV with the history of drug abuse. Persistent generalised lymphadenopathy may develop in HIV before the patient fulfils the criteria of AIDS. As the disease progresses, there is atrophy of the lymph nodes. Less likely is pulmonary tuberculosis which can also cause any abnormality on CXR, and involve peripheral lymph nodes. The others are unlikely to cause lymphadenopathy.

[Q: 1046] OnExamination - Infectious disease

An otherwise asymptomatic 22-year-old HIV positive male presents to the Infectious Diseases clinic.

Investigations reveal?

"viral load" 750,000 copies/ml

CD4 count 200x10⁶/ml (500-1600).

What is the most appropriate treatment strategy for this patient?

- 1- Start antiretroviral therapy
- 2- Start antiretrovirals when count is 150
- 3- Start antiretrovirals when count is 100
- 4- Start antiretrovirals together with prophylactic antibiotic therapy
- 5- Start prophylactic antibiotic therapy

Answer & Comments

Answer: 1- Start antiretroviral therapy

Both CD4 cell counts and plasma HIV RNA levels are independent predictors of clinical outcome. The most appropriate treatment strategy for this young man would be the introduction of anti retroviral therapy.

Generally, antiretroviral therapy would be initiated in asymptomatic patients with a CD4 count between 200 and 350. A HIV RNA level >30,000 copies/ml merits the introduction of antiretroviral therapy irrespective of CD4 count.

[Q: 1047] OnExamination - Infectious disease

A 28-year-old man who had had tuberculosis of the mediastinal lymph nodes diagnosed two weeks previously and who had been started on chemotherapy with rifampicin, isoniazid and pyrazinamide was admitted because of the increasing dyspnoea and stridor.

Chest X-ray showed compression of both main bronchi by carinal lymph node enlargement.

What is the next step in management?

- 1- Start prednisolone
- 2- Mediastinoscopy and biopsy
- 3- Refer for stent insertion/tracheostomy

4- Refer for urgent CT scan of the mediastinum

5- The addition of ethambutol

Answer & Comments

Answer: 1- Start prednisolone

The treatment of TB mediastinal lymphadenitis is the same as pulmonary TB. The nodes may enlarge during or after treatment as a result of hypersensitivity. Corticosteroids is effective in reducing the enlargement and hence will help the stridor and breathlessness.

[Q: 1048] OnExamination - Infectious disease

A 25-year-old male homosexual is admitted with dyspnoea and weight loss of 2 months duration. He is diagnosed with Pneumocystis pneumoniae due to AIDS.

Which of the following concerning Pneumocystis pneumonia is true?

- 1- May have an extra pulmonary presentation
- 2- It is always associated with X-ray changes
- 3- It is caused by a bacterium
- 4- Elevated serum antibodies to P. carinii are helpful diagnostically
- 5- It is best treated with intravenous pentamidine

Answer & Comments

Answer: 1- May have an extra pulmonary presentation

a-Any HIV associated condition.

b-5-15% have normal CXR (always is always false ... but not always!).

c-A fungus.

d-There is polyclonal B-cell activation in AIDS.

e-intravenous cotrimoxazole.

[Q: 1049] OnExamination - Infectious disease

A 28-year-old shop worker is referred with a 3 month history of recurrent episodes of disorientation and confusion. Her boyfriend has found her wandering around the house on several occasions, apparently with no idea of where she is or how she got there. Her mood has been very low, with frequent emotional outbursts, and she has considered leaving her job because of problems with working the computer and managing customers queries. Her boyfriend feels her condition is significantly worsening. Physical examination is normal, apart from recurrent, asymmetrical, jerks in all 4 limbs.

Which of the following investigations is likely to be MOST useful in reaching a diagnosis?

- 1- Chest X-Ray
- 2- CT head
- 3- EEG
- 4- Liver function tests
- 5- Visual evoked potentials

Answer & Comments

Answer: 3- EEG

This kind of rapid cognitive decline in a young person with myoclonus is strongly suggestive of CJD. This may be new variant (in which the EEG may be abnormal though is often normal) or sporadic in which case characteristic EEG abnormalities may be expected. The EEG in sporadic CJD may show significant abnormalities involving deep brain areas such as the thalami. Initially the changes are diffuse, and non-specific, developing into stereotyped high voltage components on a slow background. High voltage sharp waves may be synchronous with myoclonic jerks. Tonsillar biopsy for 14-3-3 protein marker has a diagnostic sensitivity of around 80% for Prion Proteins. Other investigations to exclude other causes of rapid cognitive decline, would

include MRI, lumbar puncture. CT may show non-specific changes with atrophy out of keeping with the patients age. Diagnosis is confirmed with biopsy.

[Q: 1050] OnExamination - Infectious disease

A 19-year-old male student attends casualty complaining of an urethral discharge one week after having casual unprotected sex. Gram stain shows numerous neutrophils, some of which contain gram-negative intracellular diplococci. The patient is treated with Ceftriaxone, 250 mg as an intramuscular injection. Five days later, the patient re-attends with persisting discharge.

Which of the following is the most likely cause of this discharge?

- 1- Chlamydia trachomatis
- 2- Penicillin-resistant Neisseria gonorrhoeae
- 3- Re-infection with Neisseria gonorrhoeae
- 4- Ureaplasma urealyticum
- 5- Urethral stricture

Answer & Comments

Answer: 1- Chlamydia trachomatis

This patient has been adequately treated for gonorrhoea and a persistent discharge would be unusual unless as is often the case, there is a co-infection. The patient is likely to have a non-specific urethritis due to Chlamydia trachomatis, requiring treatment with either doxycycline or erythromycin for 7-14 days.

[Q: 1051] OnExamination - Infectious disease

A 55-year-old Caucasian man presented to hospital with fever, intermittent rigors, and worsening fatigue. He had returned from a business trip to West Africa six months previously.

What is the most likely diagnosis?

- 1- Brucellosis
- 2- Leishmaniasis
- 3- Plasmodium falciparum malaria
- 4- Plasmodium ovale malaria
- 5- Typhoid fever

Answer & Comments

Answer: 4- Plasmodium ovale malaria

The Duffy blood group on the RBC acts as a receptor for P vivax. West Africans lack the Duffy blood group and therefore P ovale replaces P vivax in this region. Both P vivax and P ovale have a liver hypnozoite stage which can cause repeated relapses. P falciparum typically presents within the first 3 months of return. Visceral leishmaniasis is not endemic in West Africa, Brucellosis is a zoonosis, transmitted through contaminated and untreated milk and by direct contact with infected animals. The incubation period of brucellosis is usually one to three weeks, but sometimes may be several months. It may have either a sudden or insidious onset and is accompanied by continued, intermittent, or irregular fever. Typhoid fever presents within 1-3 weeks from return from an endemic area.

[Q: 1052] OnExamination - Infectious disease

A 45-year-old man presented with a three day history of headache and increasing confusion. On examination he was febrile with marked neck stiffness. Investigations revealed: Cerebrospinal fluid analysis (normal ranges are shown in brackets):

White cell count 600 /ml (< 5)

White cell differential > 90% neutrophils

Gram stain Gram-negative diplococci

Which one of the following antibiotics, given intravenously, is the most appropriate treatment?

- 1- Ampicillin

- 2- Benzylpenicillin
- 3- Cefuroxime
- 4- Ciprofloxacin
- 5- Gentamicin

Answer & Comments

Answer: 2- Benzylpenicillin

This is clearly a case of meningococcal meningitis. The commonest causes of bacterial meningitis in adults are:

Neisseria meningitidis (Gram negative diplococci)

Streptococcus pneumoniae (Gram positive diplococci)

TREATMENT OF BACTERIAL MENINGITIS

On the basis of Gram stain results:

Gram stain unavailable or no stainable organisms: Cefotaxime + ampicillin

Gram-positive cocci: Cefotaxime + vancomycin

Gram-positive bacilli: Ampicillin + gentamicin

Gram-negative cocci: Benzyl penicillin (Penicillin G)

Gram-negative bacilli: Cefotaxime + gentamicin

On the basis of CSF culture:

Streptococcus pneumoniae - If penicillin MIC < 0.06 micrograms/mL: Benzyl penicillin (Penicillin G) or cefotaxime - If penicillin MIC > 0.1 micrograms/mL (i.e. penicillin-resistant pneumococcus): Cefotaxime (+ vancomycin if susceptibility to broad-spectrum cephalosporins reduced)

Neisseria meningitidis: Benzyl penicillin (Penicillin G) *Haemophilus influenzae*: Cefotaxime *Listeria monocytogenes*: Ampicillin + gentamicin

Group B streptococcus: Benzyl penicillin (Penicillin G)

[Q: 1053] OnExamination - Infectious disease

A 20 year-old-woman presented with a solitary, crusted, thickened lesion on her face one month after returning from a holiday in Central America.

What is the most likely diagnosis?

- 1- Cutaneous anthrax
- 2- Cutaneous leishmaniasis
- 3- Impetigo
- 4- Leprosy
- 5- Onchocerciasis

Answer & Comments

Answer: 2- Cutaneous leishmaniasis

The patient has American ('New world') cutaneous leishmaniasis. The causative agents are of the *Leishmania* species, including *L. braziliensis*, *L. mexicana*, *L. panamensis* and others. The incubation period is very variable, ranging from 2 weeks to several months. A variety of clinical manifestations are described, including single or multiple lesions or mucosal disease (espundia). Lesions usually occur on sun-exposed areas. Treatment is usually with pentavalent antimonial drugs.

[Q: 1054] OnExamination - Infectious disease

A 40-year-old man has had decreased mentation with confusion as well as increasing incoordination and loss of movement in his right arm over the past 6 weeks. An MRI scan shows 0.5 to 1.5 cm lesions in cerebral hemispheres in white matter and at the grey-white junction that suggest demyelination. A stereotactic biopsy is performed, and immunohistochemical staining of the tissue reveals JC papovavirus in oligodendrocytes.

Which of the following laboratory test findings is most likely to be associated with these findings?

- 1- CD4 lymphocyte count of 90/microlitre
- 2- Haemoglobin A1c of 9.8%
- 3- HDL cholesterol of 0.7 mmol/L
- 4- Oligoclonal bands in CSF
- 5- Serum sodium of 110 mmol/L

Answer & Comments

Answer: 1- CD4 lymphocyte count of 90/microlitre

The findings are those of progressive multifocal leukoencephalopathy (PML), which is a condition that can develop in immunocompromised patients, such as those with AIDS. PML is associated with papova (JC) virus infection.

[Q: 1055] OnExamination - Infectious disease

Transplacental transmission of all of the following organisms is a recognised cause of fetal malformations and disease EXCEPT:-

- 1- Cytomegalovirus
- 2- Mumps
- 3- Rubella
- 4- Toxoplasma gondii
- 5- Varicella zoster virus

Answer & Comments

Answer: 2- Mumps

Cytomegalovirus in pregnancy can cause fetal abnormalities or abortion. Varicella is rare in pregnancy but can be severe and cause intra-uterine death of the fetus. Congenital toxoplasmosis usually results from an acute maternal infection during pregnancy. Measles and mumps cause only mild maternal infection and do not pose a serious problem to the fetus.

[Q: 1056] OnExamination - Infectious disease

A 38-year-old male with a diagnosis of HIV presents with lethargy, confusion, personality change and a seizure. CT shows multiple uniformly enhancing mass lesions in both cerebral hemispheres

What treatment is indicated?

- 1- ketoconazole
- 2- pyrimethamine and sulfonamide
- 3- rifampicin and pyrazinimide
- 4- broad spectrum antibiotics
- 5- corticosteroids

Answer & Comments

Answer: 2- pyrimethamine and sulfonamide

Cerebral toxoplasma infection gives rise to multiple ring enhancing lesions on CT and MRI scanning. Multiple cerebral abscesses are commonly present, which may result in multifocal symptoms, including visual field deficits, focal seizures, aphasia, hemiparesis or hemisensory deficits, cranial nerve palsies, or cerebellar dysfunction. Nonfocal symptoms such as a confusional state or personality disorder may manifest initially, but focal symptoms eventually appear as the disease progresses.

[Q: 1057] OnExamination - Infectious disease

A 40-year-old male presents with a long history of productive cough and breathlessness. He had complained of halitosis and exacerbations of productive sputum, chest pain and haemoptysis. Examination revealed bilateral inspiratory crackles.

Which of the following treatments is likely to decrease the frequency of his exacerbations?

- 1- cyclical antibiotic therapy
- 2- inhaled corticosteroids

- 3- nebulised bronchodilators
- 4- postural drainage
- 5- surgical resection

Answer & Comments

Answer: 4- postural drainage

This man has Bronchiectasis as evidenced by his regular production of sputum associated with breathlessness, his repeated lung infections and the signs of bilateral inspiratory crackles. Retained mucus is the most important reason why bronchiectatic patients become infected. Postural drainage is therefore the cornerstone to treating bronchiectasis and should be undertaken at least once per day and more frequently during exacerbations. There have been trials looking at regular antibiotic therapy versus symptomatic treatment in patients with cystic fibrosis colonised with pseudomonas (eg Elborn JS et al. Thorax 2000;55: 355-358) but there is currently no evidence that this approach is of benefit in bronchiectasis. Similarly inhaled corticosteroids should not be used routinely in bronchiectasis until further evidence of their effect on lung function and exacerbation frequency is available. Surgical resection as a curative procedure can be performed for localised disease when underlying causes such as primary ciliary dyskinesia have been excluded. In this patient the bilateral crackles suggests widespread disease.

[Q: 1058] OnExamination - Infectious disease

A 25-year-old Turkish woman arrived in the UK with a three month history of weight loss and intermittent fevers. On examination, the patient was emaciated, febrile (39°C) and pale, and an enlarged liver (5 cm below the costal margin) and spleen (10cm below the costal margin) were present. Investigations revealed:

Haemoglobin 7.2g/dL (11.5-16.5)

White cell count $2.4 \times 10^9/L$ (4-11)

Platelet count $117 \times 10^9/L$ (150-400)

Thick and thin films no parasites identified

CXR normal

What is the most likely diagnosis?

- 1- HIV infection
- 2- Infectious mononucleosis
- 3- Malaria
- 4- Miliary tuberculosis
- 5- Visceral leishmaniasis

Answer & Comments

Answer: 5- Visceral leishmaniasis

The ethnic origin and clinical history are typical of visceral leishmaniasis. The causative agent is usually *Leishmania donovani*. Fever, malaise, weakness and weight loss are common. Hepatosplenomegaly develops gradually and may be massive. With time, the skin develops a grey colour, and gives rise to the Indian name of the disease 'kala-azar' meaning black fever. Anaemia is a common finding and may be severe.

[Q: 1059] OnExamination - Infectious disease

A 22-year-old woman is referred to hospital with a one-week history of fever, headache and fatigue. She was a 'mail order' bride who had recently moved to the UK from Thailand to live with her new husband. Based on her travel history, *which disease can be excluded from the following list of differentials?*

- 1- Cerebral toxoplasmosis
- 2- HIV seroconversion illness
- 3- Japanese B encephalitis
- 4- Tuberculosis
- 5- Yellow fever

Answer & Comments

Answer: 5- Yellow fever

Yellow fever only occurs in tropical South America and in sub-Saharan Africa. Japanese B encephalitis has a high prevalence in southeast Asia. All of the other diseases listed are widespread globally.

See also:
<http://www.cdc.gov/travel/seasia.htm>

[Q: 1060] OnExamination - Infectious disease

A 50-year-old female presents with dyspnoea, a new murmur and fever and is diagnosed with infective endocarditis.

Which of the following is associated with the best prognosis?

- 1- Aortic valve infection
- 2- Culture negative endocarditis
- 3- Low complement levels
- 4- Staphylococcus aureus infection
- 5- Streptococcus viridans infection

Answer & Comments

Answer: 5- Streptococcus viridans infection

Features suggestive of a worse prognosis are Acute endocarditis (Staphylococcus aureus), heart failure, IV drug abuse (often left and right sided disease), prosthetic valve infection, infection of the aortic rather than mitral valve, associated rhythm disturbance. Subacute bacterial endocarditis (Streptococcus viridans) has a better prognosis.

[Q: 1061] OnExamination - Infectious disease

Which of the following is a cause of isolated B-cell immune deficiency?

- 1- Infection with measles
- 2- Multiple myeloma

- 3- Treatment with azathioprine
- 4- Treatment with corticosteroids
- 5- Treatment with cyclophosphamide

Answer & Comments

Answer: 2- Multiple myeloma

Excessive production of myeloma paraprotein is associated with progressive reduction in normal immunoglobulin levels and impairment of immune function. Azathioprine, cyclophosphamide, corticosteroids and measles infection all cause reversible impairment of cell mediated immunity.

[Q: 1062] OnExamination - Infectious disease

A 27-year-old female presents with persistent fatigue, myalgia, poor concentration and irritability following a flu like illness 18 months previously. A diagnosis of chronic fatigue syndrome is made.

What is the appropriate initial management of this patient?

- 1- Antidepressants
- 2- Cognitive behavioural therapy
- 3- ECT
- 4- Reversion therapy
- 5- Psychoanalysis

Answer & Comments

Answer: 2- Cognitive behavioural therapy

In general, in order to receive a diagnosis of chronic fatigue syndrome, a patient must satisfy two criteria: 1. Have severe chronic fatigue of six months or longer duration with other known medical conditions excluded by clinical diagnosis, and 2. Concurrently have four or more of the following symptoms: substantial impairment in short-term memory or concentration, sore throat, tender lymph nodes, muscle pain, multi-joint pain without

swelling or redness, headaches of a new type, pattern or severity, unrefreshing sleep, and post-exertional malaise lasting more than 24 hours. (source CDC) There is a RCP report on CFS from 1996. Low dose antidepressants are used in the treatment of CFS, but the suggested first line therapy should include cognitive behavioural therapy, if access to this service is available.

[Q: 1063] OnExamination - Infectious disease

A 25-year-old woman presented with a history of confusion and fever that had worsened gradually over the preceding four days. On examination she was drowsy and had mild neck stiffness. Neurological examination revealed an extensor left plantar response. A CT scan of her brain showed an area of low attenuation in the right temporo-parietal region

What is the most likely diagnosis?

- 1- Cerebral toxoplasmosis
- 2- Herpes simplex encephalitis
- 3- Listeria meningoenkephalitis
- 4- Pneumococcal meningitis
- 5- Pyogenic brain abscess

Answer & Comments

Answer: 2- Herpes simplex encephalitis

Herpes simplex encephalitis (HSE) often presents subacutely over several days with declining cerebral function. The temporal or temporo-parietal regions are affected earlier and neuro-imaging usually demonstrates this. However, temporal lobe involvement is not pathognomonic of HSE. Cerebral toxoplasmosis is the result of reactivation of toxoplasmosis in severely immunocompromised individuals. Listeriosis is associated with the consumption of soft cheese and p???. Streptococcus pneumoniae causes acute pyogenic meningitis and is often

associated with suppurative otitis media or sinusitis. Brain abscesses are usually readily demonstrable by cranial CT scans.

[Q: 1064] OnExamination - Infectious disease

A 18-year-old male presents with a 6 week history of a painful swollen right knee. He had been treated for a sexually transmitted disease 3 months ago. On examination there was a large effusion in the right knee. Synovial fluid analysis revealed a white cell count of $16 \times 10^9/L$ but culture was negative.

Which one of the following organisms is the most likely cause?

- 1- Chlamydia trachomatis
- 2- Herpes simplex
- 3- Neisseria gonorrhoea
- 4- Treponema pallidum
- 5- Trichomonas vaginalis

Answer & Comments

Answer: 3- Neisseria gonorrhoea

Bacteria are the most common cause of monoarthritis. Staphylococcus aureus and gonococci are the most common causes of septic arthritis. Neisseria gonorrhoea occurs in young adults and is often preceded by a migratory tendonitis or arthritis. Gram's stain is positive in 25% and culture positive in 50%. This patient has been treated previously for a sexually acquired infection and this maybe why the culture is negative.

[Q: 1065] OnExamination - Infectious disease

An 18-year old student presented to hospital two days after returning from visiting family in India. Within twenty four hours of his return to the UK, he suddenly developed profuse watery diarrhoea. Initially he did not have any nausea, vomiting or stomach cramps, but

these developed within a day. He described the diarrhoea as looking like cloudy watery but without any blood or mucus. He was opening his bowels over 20 times per day. On examination he looked pale; he was afebrile. Skin turgor was reduced and mucous membranes were dry.

Stool culture revealed a growth of *Vibrio cholerae*.

Which is the most appropriate antibiotic to administer?

- 1- Ceftriaxone
- 2- Doxycycline
- 3- Meropenem
- 4- Metronidazole
- 5- Piperacillin plus gentamicin

Answer & Comments

Answer: 2- Doxycycline

Cholera has a short incubation period of 24-48 hours. The illness begins with the sudden onset of painless, watery diarrhoea. The diarrhea may be accompanied later by abdominal cramps, nausea and vomiting. Patients are usually afebrile. The diarrhoea is typically described as having the appearance of 'rice water' and a faintly fishy smell. The diarrhoea may be copious and result in hypovolaemic shock unless fluids are administered.

The primary aim of treatment is to restore fluid balance; antibiotics have a secondary role. However, antibiotics have been shown to reduce fluid loss and hasten clearance of the organism from the gut.

Appropriate antibiotics include tetracycline, doxycycline, ciprofloxacin, erythromycin, and co-trimoxazole. Tetracycline is usually the first-line drug of choice, although resistance is emerging in certain parts of the world.

[Q: 1066] OnExamination - Infectious disease

A 19-year-old man presented with purulent urethral discharge. Microscopy of an urethral swab showed neutrophils but no organisms

Which of the following antibiotics should be started?

- 1- Ciprofloxacin
- 2- Co-amoxiclav
- 3- Doxycycline
- 4- Metronidazole
- 5- Penicillin

Answer & Comments

Answer: 3- Doxycycline

The diagnosis is non-gonococcal urethritis (NGU). A presumptive diagnosis of gonococcal urethritis is made if gram-negative diplococci are seen within the neutrophils. Doxycycline is the drug of choice for NGU. Alternative therapies include Erythromycin, Azithromycin, Ofloxacin and Ciprofloxacin. Chlamydia trachomatis is the commonest cause of NGU accounting for 30-50% of cases. All sexual partners at risk should be assessed and offered epidemiological treatment.

[Q: 1067] OnExamination - Infectious disease

A 70-year-old man presented to his GP with a two-day history of increasing confusion. He also complained of a headache. He was febrile on examination; nuchal rigidity was noted. A lumbar puncture was performed and CSF microscopy revealed:

WBC 800 cells/mL (< 5) 90% neutrophils. A few Gram-positive diplococci were also noted.

What is the cause of his meningitis?

- 1- *Cryptococcus neoformans*
- 2- *Haemophilus influenzae*
- 3- *Listeria monocytogenes*

- 4- Neisseria meningitidis
5- Streptococcus pneumoniae

Answer & Comments

Answer: 5- Streptococcus pneumoniae

A question on Gram-staining properties of organisms causing meningitis. Pneumococcal meningitis is commoner in older patients. Neisseria meningitidis are gram negative diplococcus, whilst Haemophilus influenzae is a gram negative bacillus. Listeria monocytogenes is a cause of neonatal meningitis, and is a small gram-positive bacillus that is carried in the intestine and vagina, and may be transmitted to the neonate during the birth process. Cryptococcus neoformans is a fungus and yeast cells may be seen on microscopic examination of the CSF.

[Q: 1068] OnExamination - Infectious disease

A 36-year-old woman presents with dyspnoea, cough and fever. Crackles are heard on auscultation of the lungs. Circulating precipitans to Micropolyspora faeni are positive.

Which of the following is the most likely diagnosis?

- 1- Malt workers' lung
2- Pigeon fanciers' lung
3- Allergic Bronchopulmonary Aspergillosis
4- Brucellosis
5- Farmers' lung

Answer & Comments

Answer: 5- Farmers' lung

Spores of Micropolyspora faeni found in moldy hay/straw are responsible for Farmer's Lung.

[Q: 1069] OnExamination - Infectious disease

Reverse transcriptase-PCR is used to amplify:

- 1- Antibodies
2- DNA
3- RNA
4- Protein
5- Plasmids

Answer & Comments

Answer: 3- RNA

Reverse transcriptase PCR is a means of amplifying RNA. The RNA is transcribed into complementary DNA (cDNA) using the enzyme reverse transcriptase, the cDNA is then amplified by conventional PCR.

[Q: 1070] OnExamination - Infectious disease

A 70-year-old woman developed herpes zoster ophthalmicus.

Which one of the following is most likely to be a complication of this condition?

- 1- Hyphaema
2- Keratitis
3- Keratoconus
4- Posterior subcapsular cataract
5- Scleromalacia

Answer & Comments

Answer: 2- Keratitis

Keratitis due to VZV may subsequently lead to iridocyclitis and secondary glaucoma.

[Q: 1071] OnExamination - Infectious disease

A 18-year-old homosexual male developed progressive pneumonia not responding to antibiotics. Methenamine silver staining of the

sputum showed small circular cyst and Giemsa staining demonstrated the small, punctate nuclei of the trophozoites and intracystic sporozoite.

Which is the most likely organism?

- 1- Toxoplasma gondii
- 2- Trypanosoma cruzi
- 3- Cryptococcus neoformans
- 4- Leishmania donovani
- 5- Pneumocystis carinii

Answer & Comments

Answer: 5- Pneumocystis carinii

The organism is Pneumocystis carinii. The organism may be identified on microscopy after (a) methenamine silver staining for the cyst phase of the organism ;(b) Giemsa staining that demonstrates the small, punctate nuclei of the trophozoites and intracystic sporozoites; or (c) fluorescence-tagged monoclonal antibody.

[Q: 1072] OnExamination - Infectious disease

A 41-year-old male has been diagnosed with infective endocarditis.

Which of the following is associated with the best prognosis?

- 1- Aortic valve infection
- 2- Intravenous drug abuse
- 3- Prosthetic valve infection
- 4- Staphylococcus aureus infection
- 5- Streptococcus viridans infection

Answer & Comments

Answer: 5- Streptococcus viridans infection

Features suggestive of a worse prognosis are Acute endocarditis (Staphylococcus aureus), heart failure, IV drug abuse (often left and right sided disease), prosthetic valve infection,

infection of the aortic rather than mitral valve, associated rhythm disturbance. Subacute bacterial endocarditis (Streptococcus viridans) has a better prognosis.

[Q: 1073] OnExamination - Infectious disease

Which of the following is correct regarding human varicella zoster immunoglobulin (VZIG)?

- 1- Is used to treat severe chicken pox infection
- 2- Is recommended for all patients with eczema exposed to chickenpox.
- 3- Is invariably protective against severe varicella.
- 4- Should be given to a 6 week old baby whose mother has developed chickenpox
- 5- Should be given to an 18 week pregnant non-immune female who has been exposed to a case of chicken pox.

Answer & Comments

Answer: 5- Should be given to an 18 week pregnant non-immune female who has been exposed to a case of chicken pox.

Answer: 5) Should be given to an 18 week pregnant non-immune female who has been exposed to a case of chicken pox.

Varicella has a secondary infection rate in household contacts of 90%. It is commonest in spring time, and the incubation period is 14-21 days. It shares the herpes virus family properties of latency and reactivation (zoster). Risks to the fetus and neonate relate to the time of infection:

" Less than 20 weeks pregnancy: congenital varicella (limb hypoplasia, microcephaly, cataracts, growth retardation, skin scarring). High mortality.

" Second to third trimester: herpes zoster in an otherwise healthy infant.

" Minus 7 days to plus 7 days after delivery: severe and even fatal disease (30% mortality). Although a live attenuated vaccine is available, it is not licensed for use in the UK.

Varicella zoster immunoglobulin is prepared from pooled plasma of UK blood donors with a history of recent chickenpox or herpes zoster. Being an immunoglobulin, it is a protein concentrate, and should be stored between 2 and 8°C. Donors are screened for HIV, hepatitis B and hepatitis C. VZIG prophylaxis is recommended for patients who fulfil all the following criteria:

" A clinical condition that increases the risk of severe varicella, (e.g. immunosuppression, neonates, pregnant women).

" No antibodies to varicella zoster.

" Significant exposure to chickenpox or herpes.

Severe or fatal varicella can occur despite VZIG prophylaxis. Active immunisation should therefore be used for susceptible immunosuppressed patients at long term risk. Clinical chickenpox occurs in 50% of those who receive VZIG prophylaxis, and 10% more will be affected sub-clinically.

[Q: 1074] OnExamination - Infectious disease

Which of the following is a contraindication to immunisation?

- 1- Infantile eczema requiring topical steroids.
- 2- Oral poliomyelitis vaccine to a child on oral steroids.
- 3- A history of prolonged jaundice.
- 4- A child with congenital adrenal hyperplasia on oral cortisone.
- 5- A child with cerebral palsy.

Answer & Comments

Answer: 2- Oral poliomyelitis vaccine to a child on oral steroids.

Answer: 2) Oral poliomyelitis vaccine to a child on oral steroids.

Common misconceptions regarding immunisations include:

" A family history of adverse reaction, or a previous history of pertussis, measles, rubella or mumps infection.

" Prematurity or low birth weight.

" Stable neurological conditions such as cerebral palsy or Down's Syndrome.

" Asthma, eczema, hayfever or snuffles.

" Contact with an infectious disease, or treatment with antibiotics or topical steroids.

" Pregnant mother or a mother who is breast feeding.

" Prolonged jaundice.

" Patients on replacement corticosteroids.

Oral polio vaccine should not be given to immunosuppressed children, their siblings or household contacts. In children with HIV, there is little evidence that they themselves will have problems, but excretion may be prolonged, and this may give rise to an increased risk of infection of HIV positive household contacts.

[Q: 1075] OnExamination - Infectious disease

The morphological appearance of Pneumocystis carinii infection in the lung is best characterised as which one of the following?

- 1- A bronchopneumonia with abscess formation
- 2- A haemorrhagic and necrotizing pneumonia

- 3- An acute respiratory distress syndrome (ARDS) with widespread hyaline membrane formation
- 4- An interstitial pneumonitis with foamy intra-alveolar exudate
- 5- An organizing bronchopneumonia

Answer & Comments

Answer: 4- An interstitial pneumonitis with foamy intra-alveolar exudate

Pneumocystis carinii is a fungal organism. In PC pneumonia, the organism is confined to the alveolar space of the lung and produce debris and cysts in the alveolar space with interstitial infiltration of lymphocytes and plasma cells. As a result, it can cause profound disturbance of oxygen exchange and fatal hypoxaemia if left untreated.

[Q: 1076] OnExamination - Infectious disease

An 85-year-old patient from an elderly care home, experiences sudden onset of dyspnea and palpitations. A pulmonary ventilation-perfusion scan is performed and indicates a high probability for a perfusion defect involving a pulmonary arterial branch.

Which of the following findings or conditions is the one that is the most important factor favouring development of her complaint?

- 1- A neutrophilia
- 2- An increased platelet count
- 3- Cirrhosis of the liver
- 4- Generalized atherosclerosis
- 5- Poor nutrition

Answer & Comments

Answer: 2- An increased platelet count

This would lead to a prothrombotic state, increasing the risk of pulmonary embolism. Cirrhosis, and possibly poor nutrition, would

lead to decreased production of coagulation factors thus prolonging the INR. A neutrophilia would suggest infection leading to ventilation defect, and not a perfusion defect. Atherosclerosis would pre-dispose to arterial thrombo-embolus.

[Q: 1077] OnExamination - Infectious disease

A 30-year-old renal transplant recipient presented with non-Hodgkin's lymphoma.

Which virus is most likely to be of aetiological significance?

- 1- Adenovirus
- 2- Cytomegalovirus
- 3- Epstein Barr virus
- 4- Herpes simplex type 1
- 5- Varicella-zoster

Answer & Comments

Answer: 3- Epstein Barr virus

EBV-associated lymphoproliferative disease may occur in individuals with inherited or acquired immunodeficiency syndromes. Approximately 1% of renal transplant recipients develop post-transplant lymphoproliferative disease (PTLD) in the first year following their transplant.

[Q: 1078] OnExamination - Infectious disease

Regarding the epidemiology of infections, which of the following statements is true?

- 1- Resistant vivax malaria is a major problem in Kenya.
- 2- Diphtheria has been eradicated in most parts of the world.
- 3- Polio has been eradicated in most parts of the world.
- 4- Tetanus has been eradicated in most parts of the world.

5- The AIDS epidemic seems to be declining worldwide.

Answer & Comments

Answer: 3- Polio has been eradicated in most parts of the world.

Answer: 3) Polio has been eradicated in most parts of the world.

Falciparum is the major resistance problem in sub-Saharan Africa. Most vivax is Chloroquine sensitive, though resistant strains are appearing in New Guinea and Indonesia. Diphtheria is still prevalent in many parts of the world. An upsurge in polio is now nearing eradication. Tetanus is still common. AIDS is increasing inexorably.

[Q: 1079] OnExamination - Infectious disease

A 45-year-old man returned from a two-week trip in Zimbabwe. Fourteen days later he presented with fever, sore throat, headaches and a widespread maculopapular rash. On examination there was generalised lymphadenopathy and a widespread maculopapular rash.

What is the most likely diagnosis?

- 1- acute HIV infection
- 2- schistosomiasis
- 3- strongyloidiasis
- 4- tick typhus
- 5- typhoid fever

Answer & Comments

Answer: 1- acute HIV infection

It is essential to exclude acute HIV in this case. Acute retroviral syndrome is said to occur in 60-80% of patients between 2 and 12 weeks following exposure to HIV. Typical symptoms include fever, pharyngitis, lymphadenopathy and a widespread macular rash. The illness

closely resembles infectious mononucleosis. During seroconversion it is likely that the HIV antibody test will be negative; the diagnosis is made by PCR of peripheral blood for HIV RNA; in acute HIV the viral load is very high.

"The time from exposure to onset of symptoms is usually 2-4 weeks, but the incubation may be as long as 10 months in rare cases (N Engl J Med 1998;339:33; N Engl J Med 1997;336:919). Typical symptoms in a review of 209 cases (J Infect Dis 1994;168:1490) included fever (96%), adenopathy (74%), pharyngitis (70%), rash" more ...

"This particular patient clearly exemplifies the classic presentation of acute primary infection"

[Q: 1080] OnExamination - Infectious disease

A 17 year-old man presented with a strongly positive Mantoux test.

Which one of the following statements regarding his immune reaction is correct?

- 1- It is a cell mediated immune response
- 2- The response is mediated by B lymphocytes
- 3- The area of induration will be less than 10 mm in diameter
- 4- The reaction typically develops within 24 hours
- 5- If a skin biopsy were taken, immunohistochemistry would show immune complex deposition

Answer & Comments

Answer: 1- It is a cell mediated immune response

The tuberculin skin test (TST) is an intradermal test for cell-mediated hypersensitivity to tuberculo-protein. A strongly positive Mantoux is an area of induration of >15mm (10 tuberculin units). The test is negative in those

who have never been exposed to infection with TB. It usually becomes positive 3-5 weeks after infection. False-negative TST are seen in debilitated and immune-deficient patients.

[Q: 1081] OnExamination - Infectious disease

Which of the following concerning IgG is correct?

- 1- It has a molecular weight of 50,000 kd.
- 2- It is monovalent.
- 3- It comprises the majority of circulating antibody in serum.
- 4- It differs from other isotypes in not being able to cross the placental barrier.
- 5- It is the major antibody produced during the primary response.

Answer & Comments

Answer: 3- It comprises the majority of circulating antibody in serum.

Answer: 3) It comprises the majority of circulating antibody in serum.

- a) Each light chain has a MW of 25,000 and each H chain a MW of 50,000. Therefore, since the whole molecule consists of 2 L and 2 H chains, the MW is 150,000 kd.
- b) It exists as a monomer with 2 Fab portions, each of which can interact with an antigenic determinant. Therefore it is divalent.
- c) Normal range 8-19 g/l. Next is IgA, 1-5 g/l, followed by IgM 0.5- 2 g/l.
- d) It is in fact the only antibody capable of crossing the placental barrier, which it does through gaining attachment via its Fc portion.
- e) It is the major antibody produced in the secondary immune response. IgM is the major antibody produced during the primary response.

[Q: 1082] OnExamination - Infectious disease

A 75-year-old female presents with an acute infective exacerbation of her long standing Chronic Obstructive Airways Disease. Blood gas analysis whilst she was receiving Oxygen shows:

pH 7.14
pO₂ 18 kPa (11.3-12.5)
pCO₂ 10.5 kPa (4.7-6.0)

What is the most appropriate immediate management for this patient?

- 1- CPAP
- 2- Doxapram infusion
- 3- Invasive Ventilation
- 4- nebulised salbutamol with ipratropium
- 5- reduce inspired oxygen concentration

Answer & Comments

Answer: 5- reduce inspired oxygen concentration

This patient's blood gases show she is receiving too high a concentration of oxygen which is likely to have precipitated her hypercapnic acidosis. Patients with COPD should not in general receive more than 24-28% oxygen without arterial blood gas monitoring. Reduction of FiO₂ may be sufficient to improve this lady's acidosis. Once this is done she should be treated with nebulised B/D driven on air and if she fails to improve despite controlled oxygen and bronchodilators NIV is indicated.

[Q: 1083] OnExamination - Infectious disease

A 15-year-old boy is referred by his GP with a two-week history of general malaise, fatigue and pharyngitis. On examination, multiple small lymph nodes were palpable in the neck, axillae and groins. Investigations revealed:

Haemoglobin 12.5g/dL
 WBC $16.0 \times 10^9/L$
 Platelets $160 \times 10^9/L$
 Blood film Lymphocytosis noted

What is the most likely diagnosis?

- 1- Acute lymphoblastic leukaemia
- 2- Cytomegalovirus infection
- 3- Epstein-Barr virus infection
- 4- Hodgkin's disease
- 5- Toxoplasmosis

Answer & Comments

Answer: 3- Epstein-Barr virus infection

Acute EBV typically presents with a history of 1-2 weeks of fatigue and malaise, fever, pharyngitis, and symmetrical, bilateral lymphadenopathy. Heterophil antibody tests are usually positive. Mild transient thrombocytopenia is not uncommon in EBV infectious mononucleosis. CMV mononucleosis has a lower incidence of pharyngitis and cervical adenopathy. Primary Toxoplasmosis is acquired via ingestion of undercooked meat containing toxoplasma cysts or ingestion of fresh food contaminated by toxoplasma excreted in cats' feces. The infection is asymptomatic in 80-90% of immunocompetent patients. Highly characteristic of toxoplasmosis is asymmetrical lymphadenopathy limited to an isolated lymph node group. Patients with toxoplasmosis have little or no fever, fatigue, or pharyngitis. CMV infectious mononucleosis may be indistinguishable in clinical presentation from EBV but is usually not accompanied by posterior cervical adenopathy; non-exudative pharyngitis is minimal or absent. The diagnosis of ALL and HD is made by a combination of blood film examination, bone marrow aspiration and biopsy and lymph node biopsy.

[Q: 1084] OnExamination - Infectious disease

A 38-year-old woman is referred to casualty with bilateral weakness in her legs. She also complains of general malaise. Three weeks previously she had returned from a four-week tour of Eastern Europe. On examination she appeared unwell and was pyrexial (38.9°C). She has large palpable cervical lymph nodes bilaterally. Her pharynx was inflamed with areas of exudate on the pharyngeal wall. Neurological examination revealed global weakness of both legs and absent reflexes.

What is the most likely diagnosis?

- 1- Cytomegalovirus infection
- 2- Diphtheria
- 3- Epstein-Barr virus infection
- 4- Hodgkin's disease
- 5- Streptococcal tonsillitis

Answer & Comments

Answer: 2- Diphtheria

The break down of healthcare services in the former USSR was associated with a major resurgence of diphtheria. Pharyngeal diphtheria presents with fever, sore throat, cervical lymphadenopathy and an adherent, grayish pharyngeal membrane. The diphtheria toxin causes cardio- and neurotoxicity. Treatment consists of antibiotic therapy and diphtheria antitoxin.

[Q: 1085] OnExamination - Infectious disease

*Which of the following would be indicated in the treatment of a 30-year-old HIV positive male with *Pneumocystis carinii* pneumonia? Blood gases reveal a P_{O_2} of 55mmHg whilst breathing 28% oxygen.*

- 1- Atovaquone
- 2- Clindamycin
- 3- Leucovorin

4- Pentamidine

5- Trimethoprim-sulphamethoxazole

Answer & Comments

Answer: 5- Trimethoprim-sulphamethoxazole

This patient has severe PCP as suggested by the hypoxia (pO₂ less than 70). He should be treated with high percentage oxygen and the drug of choice is high dose IV cotrimoxazole (trimethoprim-sulphamethoxazole). If allergic to co-trimoxazole, IV pentamidine or Clindamycin are appropriate. IV leucovirin and oral atovaquone are further options but are not first line therapies. Prednisolone has been shown to reduce mortality substantially in patients with a PO₂ < 60mmHg.

[Q: 1086] OnExamination - Infectious disease

A 70-year-old lady presented with dyspnoea and fever. She has a history of weight loss which has been investigated with colonoscopy which found a tumour of the sigmoid colon and she is awaiting surgery. On examination she has a systolic murmur and and ECHO shows vegetations on the mitral valve. A diagnosis of infective endocarditis is made.

Which of the following organisms is associated with a high incidence of colorectal tumours?

- 1- Campylobacter jejuni
- 2- Enterococcus faecalis
- 3- Escherichia coli
- 4- Salmonella typhi
- 5- Streptococcus bovis

Answer & Comments

Answer: 5- Streptococcus bovis

Up to half of patients presenting with Streptococcus bovis endocarditis have colorectal tumours.

[Q: 1087] OnExamination - Infectious disease

A 25-year-old-man presented with severe headache, myalgia and a blanching red macular rash. He had returned from Indonesia three days previously. On examination his blood pressure was 75/50 mmHg. A diagnosis of dengue fever was made.

Which of the following would be given immediately?

- 1- A single dose of ivermectin
- 2- Intravenous hydrocortisone 200 mg
- 3- Intravenous normal saline
- 4- Metronidazole
- 5- Tetracycline

Answer & Comments

Answer: 3- Intravenous normal saline

Dengue is transmitted by Aedes aegyti mosquito in endemic areas. There are 4 serotypes. Re-infection with a different serotype aggravates the infection and is associated with serious complications such as dengue haemorrhagic fever (DHF) and dengue shock syndrome (DSS). Treatment is supportive with fluid replacement, blood transfusion and correction of clotting. Corticosteroids have no role.

In the first few days the rash is macular, blanching and transient. The second rash which looks like measles and is morbilliform, maculopapular, sparing palms and soles.

Don't confuse Dengue fever with Dengue hemorrhagic fever.

[Q: 1088] OnExamination - Infectious disease

Toxoplasmosis

- 1- can present with fits in patients with AIDS
- 2- infection in the first trimester of pregnancy is seldom harmful to fetus

- 3- raw eggs are an important source of infection
- 4- infection usually by respiration
- 5- prophylactic immunoglobulins should be given to pregnant women if their IgM anti-toxoplasma antibodies detected.

Answer & Comments

Answer: 1- can present with fits in patients with AIDS

Transmission of *Toxoplasma gondii* after ingestion of cysts from contact with cat faeces or raw / undercooked meat. Definitive host is the cat. Oocysts excreted with cat faeces can remain in soil for months. Risk of fetopathy reduced by > 50% if spiramycin given to mothers, which can prevent maternal-fetal transmission.

[Q: 1089] OnExamination - Infectious disease

A 52-year-old woman was admitted with malaise and leg weakness. Her illness started with a sore throat while travelling in Eastern Europe. On examination she was febrile (39.1°C) with several areas of exudates on her pharynx and extensive cervical lymphadenopathy. There was weakness of the legs with absent tendon reflexes.

What is the most likely diagnosis?

- 1- Acute myeloid leukaemia
- 2- Cytomegalovirus infection
- 3- Diphtheria
- 4- Glandular fever
- 5- Streptococcal tonsillitis

Answer & Comments

Answer: 3- Diphtheria

This history of severe exudative pharyngitis in a person who has recently travelled to eastern Europe is highly suggestive of diphtheria. The

disease, caused by *Corynebacterium diphtheriae*, causes a severe pharyngitis with extensive soft tissue swelling and lymphadenitis that produces a characteristic 'bull neck' appearance. Exotoxins produced by the organism may cause myocarditis or neurological defects. The degree of neurological toxicity varies, but may be severe, causing cranial neuropathies, predominantly motor peripheral neuropathy (occasionally sensory neuropathy). An epidemic of diphtheria began in Russia in the early 1990s and remains a significant public health problem in Russia and in the former Soviet states.

[Q: 1090] OnExamination - Infectious disease

*Regarding pneumonia caused by *Legionella pneumophila*, which of the following is true?*

- 1- is associated with hyponatremia
- 2- is best treated with intravenous amoxicillin and clavulanic acid
- 3- is common in AIDS patients
- 4- is readily diagnosed by standard aerobic culture of sputum
- 5- should be managed on the ward in a respiratory isolation cubicle

Answer & Comments

Answer: 1- is associated with hyponatremia

Legionella pneumophila is a Gram-negative bacillus that is ubiquitous in the environment. Human infection occurs when a sufficient inoculum of bacteria are aerosolised and inhaled. A variety of environmental sources have been identified as reservoirs of *Legionella* and have been responsible for infection in humans, including air conditioners, humidifiers, shower units and jacuzzis. *Legionellae* do not grow on standard culture media, but require specific supplemented media; they grow best at a low pH. *Legionella*

pneumonia is commoner in men than women (3:1). Other factors that predispose to infection include smoking, alcoholism, old age, chronic illness, immunosuppressive therapy. Legionella is not common in AIDS, though patients with advanced disease will be at increased risk. Erythromycin or clarithromycin are the antibiotics of choice; alternatives include doxycycline, co-trimoxazole or ciprofloxacin.

More:

<http://www.emedicine.com/med/topic1273.htm>

[Q: 1091] OnExamination - Infectious disease

A 17-year-old male from India presents with fever of 4 months duration and splenomegaly.

What is the most likely diagnosis?

- 1- Coccidiomycosis
- 2- Giardiasis
- 3- Tropical sprue
- 4- Typhoid
- 5- Visceral leishmaniasis

Answer & Comments

Answer: 5- Visceral leishmaniasis

Visceral leishmaniasis (Kala-azar) is an endemic disease in several regions of India and sub-Saharan Africa. It is caused by the parasite *Leishmania donovani* and spread by *Phlebotomus* sand-flies. Leishmaniasis is common in immune-suppressed patients, particularly those infected with HIV. There has recently been a substantial increase of cases in the Mediterranean region. It has been estimated that 15% of HIV positive drug users in Spain are infected with *Leishmania donovani* infantum. Giardiasis and tropical sprue present with gastrointestinal symptoms and malabsorption. Typhoid is an acute illness.

Coccidiomycosis is largely confined to the Americas. Most patients present with pulmonary symptoms although disseminated disease can occur particularly in the immune-suppressed.

[Q: 1092] OnExamination - Infectious disease

A 70-year-old man is admitted to the cardiology ward with a diagnosis of *Streptococcus bovis* infective endocarditis.

Which of the following investigations would be indicated?

- 1- Colonoscopy
- 2- Cystoscopy
- 3- Lymph node biopsy
- 4- Sialogram
- 5- Thoracoscopy

Answer & Comments

Answer: 1- Colonoscopy

The association between *Streptococcus bovis* bacteremia and colonic neoplasia is well described. (Arch Surg. 2004;139:760-765). The consensus of opinion is that all subjects should undergo evaluation including investigation of the GI tract. If investigation is clear then further tests should only be performed where there are symptoms or signs to suggest malignancy in other areas.

[Q: 1093] OnExamination - Infectious disease

A 43-year-old man has had vague malaise for three weeks. Physical examination is normal, except for a blood pressure of 150/95 mmHg and pitting oedema of the legs to the knees. Dipstick urinalysis shows no glucose, blood, ketones, nitrite, or urobilinogen, and the microscopic urinalysis reveals no RBC/hpf and only 1 WBC/hpf. Additional laboratory testing reveals a 24 hour urine protein of 4.1 gm. His

serum creatinine is 350 micromol/L with urea of 30 mmol/L. His hepatitis B surface antigen is positive.

Which of the following conditions is he most likely to have?

- 1- Membranous glomerulonephritis
- 2- Systemic lupus erythematosus
- 3- Acute tubular necrosis
- 4- Diabetic nephropathy
- 5- Post-streptococcal glomerulonephritis

Answer & Comments

Answer: 1- Membranous glomerulonephritis

Membranous glomerulonephritis is an antibody mediated disease in which the immune complexes localize to the subepithelial aspect of the capillary loop. That is, between the outer aspect of the basement membrane and the podocyte (epithelial cell).

The immune complexes develop in situ or, less likely, by the deposition of circulating immune complexes. The antibody may bind to an intrinsic glomerular antigen or to an exogenous antigen planted on the capillary wall.

Approximately 25 to 30% of cases are secondary. Common associations include:

- " Systemic lupus erythematosus and other connective tissue disorders
- " Drugs (gold, penicillamine, non-steroidal anti-inflammatory agents)
- " Hepatitis B, syphilis, quartan malaria, leprosy, schistosomiasis
- " Carcinoma, melanoma, leukemia, non-Hodgkin's lymphomas.

Membranous glomerulonephritis is more common in adults and most patients are older than 30 years at diagnosis. Membranous glomerulonephritis accounts for 35-50% of cases of adult nephrotic syndrome. Most

patients present with heavy proteinuria, most commonly in the nephrotic range, that is insidious in onset. A few patients have accompanying microscopic hematuria.

[Q: 1094] OnExamination - Infectious disease

Which of the following is true of Koplik's spots?

- 1- Are diagnostic of Measles
- 2- Located opposite the incisor teeth.
- 3- Only appear when fever is over 39C
- 4- They appear as red papules on the palmar surface of the hands
- 5- Typically appear two days after the rash.

Answer & Comments

Answer: 1- Are diagnostic of Measles

Koplik's spots are small, irregular, bright red spots with blue-white centres, occurring on the inside of the cheek next to the premolars. Seen only in measles they are diagnostic. The spots usually occur briefly after the fever begins and a couple of days before the generalized rash appears. Not infrequently, the spots disappear as the eruption develops.

[Q: 1095] OnExamination - Infectious disease

A 43-year-old woman develops a progressive, ascending motor weakness over several days. She is hospitalized and requires intubation with mechanical ventilation. She is afebrile. A lumbar puncture is performed with normal opening pressure and yields clear, colorless CSF with normal glucose, increased protein, and cell count of 5/microliter, all lymphocytes. She gradually recovers over the next month.

Which of the following conditions most likely preceded the onset of her illness?

- 1- Ketoacidosis
- 2- Staphylococcus aureus septicemia

- 3- Systemic lupus erythematosus
- 4- Viral pneumonia
- 5- Vitamin B₁₂ deficiency

Answer & Comments

Answer: 4- Viral pneumonia

She has Guillain-Barre syndrome often preceded by an episode of infection such as viral (CMV) or bacterial (Campylobacter).

[Q: 1096] OnExamination - Infectious disease

A 49-year-old man with a long history of alcoholism presents with cough, haemoptysis and pleuritic chest pain. He has had night sweats and 10 kg weight loss in the last three months. On chest X-ray there is a subtle nodular pattern throughout the lung.

He underwent a transbronchial biopsy which showed multinucleated giant cells, epithelioid cells and necrotic debris.

Which of the following is the most likely diagnosis?

- 1- Aspergillosis
- 2- Pneumocystis carinii pneumonia
- 3- Small cell carcinoma
- 4- Squamous cell carcinoma
- 5- Tuberculosis

Answer & Comments

Answer: 5- Tuberculosis

The history, in itself, of night sweats, haemoptysis and the miliary shadowing in an alcoholic is highly suggestive of TB. The giant cells, part of granulomas would again be supportive of TB.

[Q: 1097] OnExamination - Infectious disease

A 42-year-old man with advanced HIV disease

presented with a tonic-clonic seizure. He had been diagnosed with HIV 10 years previously, but had elected not to take antiretroviral therapy. A CT scan of his brain showed a 2 cm ring-enhancing lesion in the right parietal lobe.

What is the probable causative agent?

- 1- Cryptococcus neoformans
- 2- Mycobacterium avium intracellulare
- 3- Mycobacterium tuberculosis
- 4- Pneumocystis carinii
- 5- Toxoplasma gondii

Answer & Comments

Answer: 5- Toxoplasma gondii

This is a typical presentation with AIDS-related cerebral toxoplasmosis. The differential diagnosis of ring-enhancing lesions on CT in a patient with AIDS include (1) Cerebral toxoplasmosis (2) abscesses (3) metastases (4) atypical CNS lymphoma. Cryptococcus typically causes a meningitis. CNS infections with the remaining organisms are rare in AIDS.

[Q: 1098] OnExamination - Infectious disease

One of the surgical wards in your hospital notes an outbreak of Methicillin-resistant Staphylococcus aureus (MRSA) infections.

What is the best mechanism for reducing further transmission of this infection?

- 1- Cleaning the floors and walls of the ward with chlorhexidine
- 2- Close the ward for one month
- 3- Encourage regular hand washing by ward staff
- 4- Screen ward staff using nasal swabs and exclude those with positive cultures for MRSA
- 5- Treatment of culture-positive patients with vancomycin

Answer & Comments

Answer: 3- Encourage regular hand washing by ward staff

Cross-infection via hands of medical and nursing staff is a very important vehicle of transmission of MRSA. Hand washing before and after contact with patients is the single most effective measure to control hospital spread of this organism. Screening of ward staff is appropriate only in certain situations and should not be carried out unless recommended by the hospital infection control team. Vancomycin should never be used for MRSA decolonization. The hospital infection control policy should outline which patients should be screened and when decolonization should be attempted.

[Q: 1099] OnExamination - Infectious disease

In herpes simplex encephalitis which of the following statements is correct?

- 1- brain MRI is characteristically normal
- 2- temporal lobe involvement is common
- 3- fits are uncommon
- 4- cold sores or genital herpes are usually present
- 5- viral identification by PCR on cerebrospinal fluid is non-specific

Answer & Comments

Answer: 2- temporal lobe involvement is common

MRI brain normally shows changes in the temporal lobes. Presenting features include fever, headache, vomiting, reduced consciousness and seizures. There may be dysphasia, hallucinations and peculiar behaviour. There are usually no skin manifestations of herpes simplex infections. The virus is rarely isolated from CSF but may be detected by PMR.

[Q: 1100] OnExamination - Infectious disease

A 55-year-old female is admitted with a chest infection. Investigations reveal consolidation in the right base on the chest X-ray and urinary legionella antigen is found to be positive.

Which one of the following is the most appropriate treatment for this woman?

- 1- Cefotaxime
- 2- Clarithromycin
- 3- Co-Amoxiclav
- 4- Minocycline
- 5- Vancomycin

Answer & Comments

Answer: 2- Clarithromycin

The most appropriate treatment for Legionellosis is clarithromycin. Ciprofloxacin is also a useful drug in combination with clarithromycin for severe infections or alone in those intolerant of macrolides.

[Q: 1101] OnExamination - Infectious disease

A 44-year-old man with advanced HIV/AIDS presents with a two-week history of fever, weight loss (8kg) and sweats. His latest CD4 T-lymphocyte count (taken four weeks previously) was 20 cells/mm³. He had failed multiple regimens of antiretroviral therapy and was not currently taking any prescribed medications other than co-trimoxazole as prophylaxis against *Pneumocystis carinii* pneumonia.

Investigations:

Hb 8.2 g/dL

WBC (total) $2.1 \times 10^9/L$

Platelets $75 \times 10^9/L$

A bone marrow aspirate showed acid/alcohol fast bacilli on light microscopy.

Which one of the following mycobacteria is the most likely cause of his presenting illness?

- 1- Mycobacterium avium
- 2- Mycobacterium bovis
- 3- Mycobacterium chelonae
- 4- Mycobacterium fortuitum
- 5- Mycobacterium marinum

Answer & Comments

Answer: 1- Mycobacterium avium

Mycobacterium bovis and Mycobacterium tuberculosis are classified as 'typical' mycobacteria that cause a similar spectrum of disease. As its name suggests, M. bovis also causes disease in cattle and the usual source of human infection was from drinking contaminated milk; this is now rare. BCG is a live attenuated vaccine derived from a strain of M. bovis. BCG is currently used as a form of immunotherapy for treating bladder cancer; several cases of disseminated M. bovis infection (systemic 'BCG-it is') have been described as a result of systemic infection following this treatment.

The other organisms listed are non-tuberculous mycobacteria (NTM); sometimes referred to as 'atypical' mycobacteria. They differ from M. tuberculosis in that they are ubiquitous organisms and have no person-to-person spread.

Mycobacterium avium (also known as Mycobacterium avium complex (MAC), or Mycobacterium avium intracellulare (MAI)) causes disseminated infection in patients with advanced HIV, typically when the CD4 count is less than 50 cells/mm³. This is a disseminated infection that usually causes symptoms of fatigue, weight loss and fevers. Bone marrow infiltration is typical and patients are often anaemic and/or pancytopenic. The diagnosis is best made from bone marrow aspiration and culture. It may also be detected in blood cultures.

M. fortuitum, and M. chelonae typically present as painful papular, nodular or ulcerating skin lesions. Both are classified as a rapidly growing mycobacteria and infect immunocompetent individuals. It is a natural environmental organism that has been found in water sources, sewage and dirt. Other manifestations include osteomyelitis, lymphadenitis, and ocular disease (keratitis and corneal ulceration), usually a result of wound contamination after trauma.

Disseminated disease may be seen in immunosuppressed patients.

Mycobacterium marinum infection occurs when contaminated water is exposed to skin that has experienced open trauma. It is an uncommon infection that is usually seen in patients who handle fish or swim in freshwater or saltwater. The skin is the most common site of infection, where it usually produces a solitary indolent granulomatous lesion, the 'fish tank granuloma'.

[Q: 1102] OnExamination - Infectious disease

A 17-year-old man presented with a widespread maculopapular rash. He had been prescribed Amoxicillin for exudative tonsillitis.

What is the most likely diagnosis?

- 1- acute HIV infection
- 2- cytomegalovirus infection
- 3- infectious mononucleosis
- 4- parvovirus infection
- 5- streptococcal infection

Answer & Comments

Answer: 3- infectious mononucleosis

This patient has the typical features of glandular fever and is confirmed by the typical rash following the introduction of amoxicillin. This rash is considered almost pathognomonic of glandular fever and will subside following

withdrawal of amoxicillin. There are no other features in this patients history to suggest an alternative diagnosis.

[Q: 1103] OnExamination - Infectious disease

Which of the following micro-organisms is generally sensitive to Benzylpenicillin?

- 1- Bordetella pertussis
- 2- Cryptococcus neoformans
- 3- Mycoplasma pneumoniae
- 4- Legionella pneumophila
- 5- Streptococcus Pneumoniae

Answer & Comments

Answer: 5- Streptococcus Pneumoniae

Penicillin binds to specific penicillin-binding proteins (PBP's) in the cell wall, mainly of gram positive organisms. Penicillin resistance is usually due to production of altered PBPs or beta-lactamases which leave the ... Penicillin is mainly useful for Group A Strep., Group B Strep., meningococcal and pneumococcal infections, though anthrax are also sensitive. Pneumococci with modified PBPs are an increasing problem.

[Q: 1104] OnExamination - Infectious disease

A 60-year-old man was admitted with community-acquired pneumonia and deteriorated over the next few hours.

Which one of the following indicates a poor prognosis?

- 1- A total white cell count of $17 \times 10^9/L$ (4-11)
- 2- Blood pressure of 110/70 mm Hg
- 3- Respiratory rate of 35 breaths/min
- 4- Rigors
- 5- Temperature of 39°C

Answer & Comments

Answer: 3- Respiratory rate of 35 breaths/min

The presence of raised urea ($>7\text{mM}$), hypotension (diastolic BP equal or $<60\text{mmHg}$) and respiratory rate equal or $> 30/\text{min}$ is associated with significantly increased risk of death. Other less important features of severe pneumonia include older age (>60), comorbidity, confusion, cyanosis, WBC <4000 or > 30000 , hypoxia and CXR with multilobe involvement.

[Q: 1105] OnExamination - Infectious disease

A 15 year-old girl presented with a 12-hour history of fever and global headache. On examination she was febrile (37.5°C). She was fully conscious. Mild neck stiffness was noted but there were no other neurological signs. Cerebrospinal fluid analysis showed:

Cell count $200/\text{mL}$ (60% lymphocytes)

Protein 0.8 g/L

Glucose 4.3 mmol/L

Gram stain

No organisms seen

What is the most likely diagnosis?

- 1- Bacterial meningitis
- 2- Cryptococcal meningitis
- 3- Lymphomatous meningitis
- 4- Tuberculous meningitis
- 5- Viral meningitis

Answer & Comments

Answer: 5- Viral meningitis

Enteroviruses and mumps are the commonest causes of viral meningitis. CSF changes with bacterial meningitis typically include high protein, low glucose and neutrophil pleocytosis. Cryptococcal meningitis is an infection of severely immunocompromised

individuals, especially advanced HIV infection. Tuberculous meningitis is an insidious illness, presenting over weeks and months.

[Q: 1106] OnExamination - Infectious disease

Three elderly patients presented with cough, fever and general malaise on return from holiday to Spain. The group of 50 had travelled together visiting forestry on the hills together with fishing trips in mountain streams. They had been housed in differing hotels. The three people who presented with illness all stayed in the same hotel.

Which of the following organisms is most likely to be responsible for their illness?

- 1- Borelia Burgdorferi
- 2- Legionella pneumophila
- 3- Leptospira icterohaemorrhagica
- 4- Mycoplasma pneumoniae
- 5- Pneumococcus

Answer & Comments

Answer: 2- Legionella pneumophila

This is a typical story for legionnaire's disease caused by Legionella pneumophila. The condition was described first in a veteran's legion conference in a similar fashion to the above description. Contaminated air conditioning units are often to blame. Weil's disease is unlikely given the story as is Lyme disease (Borelia burgdorferi).

[Q: 1107] OnExamination - Infectious disease

One of the nurses working on the Care of the Elderly ward sustains a needlestick injury while taking blood from a patient.

What is the most appropriate immediate management?

- 1- Administer prophylactic hepatitis B immunoglobulin regardless of vaccine status
- 2- Exclude the nurse from performing exposure-prone procedures for three months until a negative HIV antibody test has been obtained
- 3- Immediately take the nurse's blood to test for antibodies to hepatitis B, hepatitis C and human immunodeficiency viruses
- 4- Promptly administration of antiretroviral therapy
- 5- Wash the wound with soap under running water

Answer & Comments

Answer: 5- Wash the wound with soap under running water

The first line of management of needlestick injuries includes immediate washing under running water. All incidents should be reported to occupational health department and have a careful risk assessment. HBIG is given only if donor is known Hepatitis B positive and victim is non-immune. Antiretroviral therapy is given, after counseling, if donor is known HIV positive and the exposure is deemed high risk.

[Q: 1108] OnExamination - Infectious disease

A 45-year-old woman was diagnosed with bacterial endocarditis.

What is the characteristic fundoscopic feature of this disease?

- 1- Cherry red macula
- 2- Janeway lesions
- 3- Macular star
- 4- Retinal artery aneurysms
- 5- Roth's spots

Answer & Comments

Answer: 5- Roth's spots

Roth's spots are the fundoscopic hallmark of bacterial endocarditis. Other features include Osler's nodes (tender subcutaneous nodules caused by immune complex deposition), and Janeway lesions (caused by infective emboli in the skin).

[Q: 1109] OnExamination - Infectious disease

Primary Pulmonary tuberculosis:

- 1- Leads to pleural effusion
- 2- Is highly infective
- 3- Commonly leads to miliary TB
- 4- May be totally asymptomatic
- 5- Usually produces cavitation

Answer & Comments

Answer: 4- May be totally asymptomatic

Primary Pulmonary tuberculosis is often asymptomatic consisting of primary complex. Cavitation and pleural effusions are a manifestations of post primary TB.

[Q: 1110] OnExamination - Infectious disease

A 68-year-old woman presents to Casualty with a two day history of pain and swelling of the right ankle. She could not recall any history of recent trauma. On examination she was febrile, temperature 38.1 C. The right ankle was swollen and very tender with a reduced range of movement.

Which of the following investigations would be of most help in establishing the diagnosis?

- 1- Aspiration of the right ankle
- 2- Blood cultures
- 3- Erythrocyte sedimentation rate
- 4- Serum urate level

5- X-ray of the right ankle

Answer & Comments

Answer: 1- Aspiration of the right ankle

Septic arthritis is a medical emergency and this is the most likely diagnosis in this case. It is essential that the joint is aspirated in order to establish a microbiological diagnosis that will guide appropriate treatment. All of the other investigations listed would be of value in managing this patient, but in this setting joint aspiration is critical.

[Q: 1111] OnExamination - Infectious disease

A 23-year-old male presented with a two-week history of dysuria and purulent penile discharge.

Gram stain of a urethral swab showed Gram-negative intracellular diplococci.

Which one of the following is the most likely causative organism?

- 1- Chlamydia trachomatis
- 2- Cytomegalovirus
- 3- Mycoplasma hominis
- 4- Neisseria gonorrhoeae
- 5- Ureaplasma urealyticum

Answer & Comments

Answer: 4- Neisseria gonorrhoeae

Neisseria gonorrhoea occurs in young adults and is often preceded by a migratory tendonitis or arthritis. Gram's stain is positive in 25% and culture positive in 50%. Neisseria gonorrhoeae is a species of Gram-negative bacteria responsible for the disease gonorrhoea. They are highly fastidious gram-negative cocci, that is, they require special nutrients to survive. These cocci typically appear in pairs (diplococci).

[Q: 1112] OnExamination -
Infectious disease

A 72-year-old gentleman presents with increasing shortness of breath, fever and cough. A chest X ray shows findings consistent with a right middle lobe pneumonia.

Which factor is associated with a worse prognosis?

- 1- Blood pressure of 120/80 mmHg
- 2- Respiratory rate of 18/min
- 3- Temperature of 37.2
- 4- Urea of 18 mmol/l
- 5- White cell count of 15x10⁹

Answer & Comments

Answer: 4- Urea of 18 mmol/l

BTS guidelines suggest increasing age, co-morbidity, respiratory rate above 30/min, BP less than 90 systolic, hypoxaemia, WCC less than 4 or greater than 20 x10⁹, chest radiographic signs, positive blood cultures, confusion and urea above 7 mmol/l are indicators of a worse prognosis associated with community acquired pneumonia.

[Q: 1113] OnExamination -
Infectious disease

A 26-year-old previously healthy woman has the sudden onset of mental confusion. She has a seizure and is brought to the hospital. Her vital signs show blood pressure 100/60 mm Hg, temperature 37 C., pulse 89, and respirations 22. A lumbar puncture reveals a normal opening pressure, and clear, colorless cerebrospinal fluid is obtained with 1 RBC and 20 WBC's (all lymphocytes), with normal glucose and protein. An MRI scan reveals swelling of the right temporal lobe with hemorrhagic areas.

Which of the following infectious agents is the most likely cause for these findings?

- 1- Haemophilus influenzae

- 2- Herpes simplex virus
- 3- Influenza virus
- 4- Mycobacterium tuberculosis
- 5- Neisseria meningitidis

Answer & Comments

Answer: 2- Herpes simplex virus

Haemorrhagic lesions of the temporal lobe are typical for Herpes simplex virus infection. Hemophilus influenzae is the organism most associated with meningitis in children. Neisseria meningitidis would cause meningitis - however, in this case there are lymphocytes not neutrophils in the CSF and a normal not low glucose.

[Q: 1114] OnExamination -
Infectious disease

Which is true of herpes simplex encephalitis?

- 1- brain MRI is characteristically normal
- 2- fits are uncommon
- 3- genital herpes is usually present
- 4- temporal lobe involvement is common
- 5- viral identification using polymerase chain reaction on CSF is non-specific

Answer & Comments

Answer: 4- temporal lobe involvement is common

Herpes simplex encephalitis (HSE) is associated with high signal in one or both temporal lobes (limbic encephalitis). Seizures are commonly present in HSE. Herpes Simplex Virus type 1 is the causative virus (Not type 2 which is associated with genital herpes). PCR for herpes simplex virus on CSF is highly specific test.

[Q: 1115] OnExamination -
Infectious disease

A 15-year-old girl presents with fever, malaise and sore throat. Examination reveals a temperature of 38.3 °C with cervical lymphadenopathy. Her results show:

Haemoglobin 12.8 g/dl (11.5-16)

White cell count $9.8 \times 10^9/L$ (4-11)

Neutrophils $3 \times 10^9/L$

Lymphocytes $4.5 \times 10^9/L$

Blood film reveals atypical mononuclear cells

What is the most likely diagnosis?

- 1- Acute Lymphoblastic Leukaemia
- 2- Brucellosis
- 3- Epstein-Barr viral infection
- 4- Hodgkin's disease
- 5- Sarcoidosis

Answer & Comments

Answer: 3- Epstein-Barr viral infection

The diagnosis is EBV infection, Infectious Mononucleosis, which may be confirmed by the presence of IgM to EBV.

[Q: 1116] OnExamination -
Infectious disease

A 45-year-old man has been diagnosed with pulmonary tuberculosis.

Which of the following investigations is essential prior to starting antituberculous therapy?

- 1- Full blood count
- 2- Liver function test
- 3- Plasma glucose
- 4- Urine for acid-fast bacilli
- 5- Vitamin B6

Answer & Comments

Answer: 2- Liver function test

Hepatotoxicity is a feature of antituberculous treatment. "Liver function should be checked before treatment for clinical cases."

[Q: 1117] OnExamination -
Nephrology

Which of the following statements regarding idiopathic membranous nephropathy is correct?

- 1- It characteristically presents in the first decade of life.
- 2- Progression to end-stage renal failure is rapid.
- 3- immune complex deposits are typically seen in the glomerular mesangium.
- 4- Males are twice as commonly affected as females.
- 5- The nephritic syndrome is a characteristic presentation.

Answer & Comments

Answer: 4- Males are twice as commonly affected as females.

Membranous nephropathy is characterised by thickened basement membranes and monotonous granular deposits of IgG and C3 distributed in the epimembranous space of virtually all glomerular capillaries. The mesangium may be involved at a later stage of the disease and is more typical of secondary disease. It is typically seen in the over 40 age group with a male predominance of 2 to 1 and is associated with a variable prognosis with 25% developing ESRF over 10 years and 25% going into remission. There is a higher rate of remission for the idiopathic form. The majority of patients manifest with a pure nephrotic syndrome. A nephritic presentation is rare.

[Q: 1118] OnExamination -
Nephrology

The following are complications of nephrotic syndrome with the exception of

- 1- acute renal failure
- 2- accelerated hypertension

- 3- hypocalcaemia
- 4- pneumococcal infection
- 5- venous thrombosis

Answer & Comments

Answer: 2- accelerated hypertension

Complications also include hyperlipidaemia, protein malnutrition and loss of binding proteins in urine. Nephrotic syndrome likely to be associated with hypocalcaemia (Vit D binding protein and Vitamin D lost in nephrotic urine) and hypovolaemia (low blood pressure).

[Q: 1119] OnExamination -
Nephrology

A 30-year-old female presents with fevers, and a 3 month history of malaise.

Results show:

Creatinine 250 micromol/l

Complement C₃ 23 mg/dL (65 - 190)

What is the likely diagnosis?

- 1- HIV nephropathy
- 2- Infective endocarditis
- 3- Membranous Nephropathy
- 4- Microscopic Polyangiitis
- 5- Minimal change nephropathy

Answer & Comments

Answer: 2- Infective endocarditis

Hypocomplementaemia is associated with either vasculitides such as SLE, cryoglobulinaemia but is also associated with a non-vasculitic process such as SBE. In this case with the 3 month history and fevers SBE is suggested. In microscopic polyangiitis, which is classically small vessel, complement would be expected to be normal.

[Q: 1120] OnExamination -
Nephrology

Which one of the following cytokines is strongly implicated in renal scarring?

- 1- interferon alpha
- 2- interleukin-1
- 3- granulocyte colony stimulating factor
- 4- transforming growth factor-beta
- 5- tumour necrosis factor alpha

Answer & Comments

Answer: 4- transforming growth factor-beta

TGF-beta is a potent recruiter for fibroblasts which are implicated in renal scarring. IFN-alpha is implicated more in lymphocyte response and IL-1/TNF-alpha in the acute phase response. G-CSF is a stimulant of granulocyte cell line maturation.

[Q: 1121] OnExamination -
Nephrology

Which one of the following statements regarding renal function is correct?

- 1- The daily solute excretion will lie between 75 and 300 mosmol
- 2- The permeability of the proximal nephron to water increases in the presence of vasopressin
- 3- The rate of ammonium excretion in urine is inversely related to the rate of urinary hydrogen ion excretion
- 4- A ten minute period of hyperventilation will normally be expected to lead to an increased rate of bicarbonate excretion in urine
- 5- Sodium reabsorption in the tubules is mainly controlled by aldosterone

Answer & Comments

Answer: 4- A ten minute period of hyperventilation will normally be expected to lead to an increased rate of bicarbonate excretion in urine

AVP acts on the collecting ducts increasing permeability to water. The total solute excretion is approximately 700 mosmol/d. Sodium reabsorption is mostly through active transport in the loop of Henle with only a modest reabsorption facilitated by aldosterone. A ten minute period of hyperventilation would cause a respiratory alkalosis leading to an increased secretion of bicarbonate and retention of Hydrogen ions. The rate of ammonium excretion is proportional to the rate of hydrogen ion excretion.

[Q: 1122] OnExamination -
Nephrology

Which of the following is a feature of cystinuria?

- 1- accumulation of cystine in the kidney
- 2- a useful response to acidification of urine
- 3- autosomal dominant inheritance
- 4- excessive urinary arginine excretion
- 5- radiolucent urinary calculi

Answer & Comments

Answer: 4- excessive urinary arginine excretion

Cystinuria is the commonest inborn error of amino acid transport. Amino acids excreted in urine are cystine, ornithine, arginine and lysine (mnemonic - COAL). The renal stones are radio-opaque due to the presence of sulphur. It is inherited as an autosomal recessive condition. Management includes alkalinization along with high fluid intake (>4 L/day); d-penicillamine may also be used.

It is cystinosis that leads to accumulation of cystine in the kidney.

[Q: 1123] OnExamination - Nephrology

Which of the following is least likely with the HLA complex?

- 1- CD8 T-cells recognise antigen when co-presented with Major histocompatibility complex (MHC) Class I
- 2- CD4 T-cells recognise antigen when co-presented with MHC Class II
- 3- Polymorphisms occur in Class I, but not Class II, MHC genes
- 4- Multiple sclerosis is associated with HLA DR2
- 5- HLA matching is more important in kidney transplantation than liver transplantation

Answer & Comments

Answer: 3- Polymorphisms occur in Class I, but not Class II, MHC genes

Polymorphisms occur in both Class I and II genes. Cytotoxic T-cells express the molecule CD8 on the cell surface and only recognise antigen when presented by the T-cell receptor (TCR) in conjunction with Class I MHC. T-helper cells express CD4 on the cell surface and only recognise antigen when presented by TCR and Class II MHC. T-helper cells divided into Th1 and Th2, depending on function & cytokines released: Th1 cells secrete IL-2 and interferon-gamma and are involved in stimulating a cytotoxic immune response; Th2 cells secrete IL-4, IL-5, IL-10 and stimulate a humoral (antibody) response by B-cells. Liver allografts are less immunogenic than kidney grafts.

[Q: 1124] OnExamination - Nephrology

Which of the following concerning the pH of urine is correct?

- 1- is a useful indicator of the acid/base balance of the blood
- 2- rises on a vegetarian diet
- 3- is determined by the concentration of ammonium
- 4- is lower than 5.5 in renal tubular acidosis
- 5- would be above 7.0 after prolonged and severe vomiting

Answer & Comments

Answer: 2- rises on a vegetarian diet

c - excretion of ammonium occurs when an acid urine is produced but the pH of urine is of course determined by the concentration of H⁺ ions d-unable to lower the pH to less than 5.5 in RTA e- This would be expected in an attempt to compensate for the loss of acid however when there is extracellular fluid depletion the retention of sodium takes priority. Instead of bicarbonate being excreted it is reabsorbed in the proximal and distal nephron and this perpetuates the metabolic alkalosis until the fluid balance is restored with IV fluids.

[Q: 1125] OnExamination - Nephrology

A 7-year-old boy is admitted with renal colic due to renal calculus. His mother has a similar history of recurrent calculi.

What is the most likely explanation for recurrent renal calculi in both mother and child?

- 1- Cystinosis
- 2- Cystinuria
- 3- Hyperoxaluria
- 4- Idiopathic hypercalciuria
- 5- Urate uropathy

Answer & Comments

Answer: 4- Idiopathic hypercalciuria

Idiopathic hypercalciuria has a familial or sporadic pattern. In the familial pattern an autosomal dominant inheritance is present. The type of the disease is identical in affected members of the same family and the typical presentation is of recurrent urinary calculi. Cystinuria, cystinosis, urate uropathy and hyperoxaluria are autosomal recessive conditions.

[Q: 1126] OnExamination -
Nephrology

A 45-year-old man presented to the Nephrology clinic with severe generalized oedema.

Investigations:

Serum albumin 20 g/L

24-hour urinary protein excretion 14.6 g (<0.2 g)

Renal biopsy Normal on light microscopy, normal on immunofluorescence

There was no significant improvement in his symptoms or signs after three months' treatment with prednisolone 60 mg OD.

What is the most likely diagnosis?

- 1- Focal segmental glomerulosclerosis
- 2- Membranous nephropathy
- 3- Minimal change disease
- 4- Myeloma
- 5- Renal vein thrombosis

Answer & Comments

Answer: 3- Minimal change disease

This patient has symptoms and signs of a nephrotic syndrome. A renal biopsy was normal on light microscopy and immunofluorescence.

Focal segmental glomerulosclerosis and membranous nephropathy are all histological diagnoses. As this patients' renal biopsy was normal, he cannot have these diagnoses.

Myeloma generally causes a cast nephropathy, but can also cause Fanconi syndrome, light chain amyloidosis, light chain deposition, infiltration of renal interstitium by plasma cells, calcium precipitation and renal infection. This may cause acute renal failure, chronic renal failure or nephrotic syndrome. All the above lesions should be visible on light microscopy of the renal biopsy.

Renal vein thrombosis is an uncommon cause of the nephrotic syndrome. It is not normally associated with such heavy proteinuria and, if it is, there are usually changes seen on microscopy.

The likely diagnosis is minimal change nephropathy. Although it is more common in children it does occur in adults and is then associated with poorer outcomes. As well as heavy proteinuria oval fat bodies may also be seen in the urine.

[Q: 1127] OnExamination -
Nephrology

In asymptomatic chronic renal failure:

- 1- there is increase in tubular excretion of urate
- 2- serum ionised [calcium] is normal
- 3- serum [phosphate] characteristically increased before GFR falls to 30ml/min
- 4- increase serum [alkaline phosphatase] mainly due to liver isoenzyme
- 5- decrease in blood pressure accompanied by increase in extracellular fluid

Answer & Comments

Answer: 2- serum ionised [calcium] is normal

Urate retention is common feature in CRF. Total serum [calcium] is reduced or at lower limits of normal, but ionised [calcium] is normal unless steps are taken to treat acidosis actively eg with sodium bicarbonate. Plasma phosphate and chloride are almost always

raised. Hyperphosphataemia occurs when GFR falls <30ml/min. Increased bone alkaline phosphatase reflects osteodystrophy. Hypertension is due largely to salt and water retention, and also overactivity of renin angiotensin systems.

[Q: 1128] OnExamination - Nephrology

An 18-year-old female student attends the clinic as her father has just died with end-stage renal failure. He had been diagnosed with autosomal dominant polycystic kidney disease. She wishes to know what investigations she requires.

Which of the following is an appropriate strategy in her management?

- 1- Geneticist referral
- 2- Glomerular Filtration Rate Estimation
- 3- MRI brain
- 4- Ultrasound of the renal tract
- 5- Urine Dipstick

Answer & Comments

Answer: 1- Geneticist referral

An ultrasound of the renal tract may not be appropriate at this patients' age, given that cysts may not become apparent until the age of 20. Gross haematuria in ADPKD carries a poor prognosis, however microscopic haematuria may be a complication. Subarachnoid haemorrhage may be a cause of mortality in 9% of patients with ADPKD, though 8% of patients have an asymptomatic intracranial aneurysm, and if the diagnosis is confirmed and there is a strong history of Subarachnoid Haemorrhage then an MRI would be indicated. Genetic counselling is most appropriate in this context and genetic linkage analysis may be utilized.

[Q: 1129] OnExamination - Nephrology

Which of the following concerning renal blood flow is true?

- 1- is 40% of the cardiac output at rest
- 2- can be measured using the Fick principle
- 3- is higher in the medulla than the cortex
- 4- is increased when renal nerves are stimulated
- 5- is decreased in response to hypoxia

Answer & Comments

Answer: 2- can be measured using the Fick principle

Renal blood flow is approximately 25% of cardiac output. The 'Fick principle' can be used to estimate RBF through clearance. RBF is higher in the cortex than medulla as one might expect with the increasing glomeruli in this region. Sympathetic stimuli produce vasoconstriction and RBF should be increased in response to hypoxia.

[Q: 1130] OnExamination - Nephrology

A 16-year-old female presents with a three year history of recurrent colicky loin pain. One year ago she passed a renal calculus.

24 hour urine collection showed normal levels of calcium, phosphate and urate, but elevated levels of arginine, cystine, lysine and ornithine.

Which one of the following features is characteristic of this condition?

- 1- Accumulation of cystine in collecting system
- 2- Autosomal dominant inheritance
- 3- Cystine deposits within the Cornea
- 4- Functional defects within the glomeruli
- 5- Radiolucent renal stone formation

Answer & Comments

Answer: 1- Accumulation of cystine in collecting system

This condition is typical of Cystinuria,/nephropathic cystinosis an autosomal recessive genetic defect in membrane transport for cystine, lysine, ornithine and arginine in epithelial cells. The disease is characterised by recurrent nephrolithiasis. Radiolucent stones are not specific for this condition and may be seen with uric acid stones.

[Q: 1131] OnExamination - Nephrology

A 30-year-old woman presented with hypertension (160/110 mmHg), elevated titres of antibodies to double-stranded DNA, and proteinuria (1g per 24 hours). A renal biopsy demonstrated WHO class II lupus nephritis (mesangial disease).

What is the most appropriate single treatment for this patient?

- 1- antihypertensive medication
- 2- high-dose corticosteroids
- 3- intravenous cyclophosphamide
- 4- oral cyclophosphamide
- 5- plasma exchange

Answer & Comments

Answer: 1- antihypertensive medication

There is good evidence that immunosuppression could alter outcome in the presence of proliferative glomerulonephritis but not in mesangial or membranous glomerulonephritis. Therefore the best line of treatment would be a conservative approach to address risk factors for progression of renal impairment such as uncontrolled hypertension. There is no good evidence to support plasma exchange as an

effective treatment modality in lupus nephritis.

[Q: 1132] OnExamination - Nephrology

A 70-year-old woman was referred with a six-week history of painless macroscopic haematuria. Her only medications were IM sodium aurothiomalate and oral ibuprofen, which she took for rheumatoid arthritis.

Investigations:

Serum creatinine 92 umol/L

Urine dipstick Blood ++++

Protein +

Abdominal plain X-Ray Normal

Ultrasound kidneys & renal tract Normal

Which one of the following is the best initial investigation?

- 1- Cystoscopy
- 2- Intravenous urogram (IVU)
- 3- Renal biopsy
- 4- Stop Ibuprofen
- 5- Stop sodium aurothiomalate

Answer & Comments

Answer: 1- Cystoscopy

This lady has macroscopic haematuria and a trace of protein in the urine. She is taking ibuprofen and IM sodium aurothiomalate (gold). Her renal function is normal, as is the plain abdominal x-ray and USS renal tract.

Ibuprofen is a common cause of interstitial nephritis, and this could present with painless haematuria. Sodium aurothiomalate commonly causes trace proteinuria, and if present on its own is unimportant, but it can also cause membranous glomerulonephritis, which this lady could have.

However, the most important thing to exclude would be a bladder tumour initially before

embarking upon a renal biopsy. Therefore cystoscopy is the best initial investigation.

[Q: 1133] OnExamination -
Nephrology

A 21-year-old female presents with a joint pains and rash. On examination her blood pressure was 140/100 mmHg. Investigations reveal:

Creatinine 90 umol/L (60-100)

anti dsDNA antibodies strongly positive (0-73)

24 hour urinary protein excretion 1.7g (<0.2)

renal biopsy membranous nephropathy

What is the most appropriate next treatment

- 1- ACE inhibitor for blood pressure control
- 2- Cyclophosphamide
- 3- NSAIDs for arthralgia
- 4- Prednisolone for immunosuppression
- 5- Warfarin anticoagulation

Answer & Comments

Answer: 1- ACE inhibitor for blood pressure control

This patient has SLE, with disease affecting her kidneys. The biopsy has shown pure membranous nephropathy, classifying the disease as class V(a) on the 1995 WHO classification of lupus nephritis. Class V(a and b) have a low rate of progression to renal failure. There is no clear consensus on treatment, but most nephrologists would start treatment with prednisolone. Cyclophosphamide could be added in later as a steroid sparing agent. Warfarin is not considered an appropriate treatment, as if this lady exhibited any pro-thrombotic tendencies (on the background of antiphospholipid antibody disease) she should be started on aspirin. Non steroidal anti-inflammatory medication would treat her arthralgia, but

would have no affect on the prognosis of the disease. As there is a low rate of progression of renal disease in this patient, the blood pressure should be aggressively treated with an ACE inhibitor, and this could assist in reducing the proteinuria. Therefore, the correct answer should be A, but closely followed by answer D.

[Q: 1134] OnExamination -
Nephrology

A 16-year-old girl developed pulmonary haemorrhage and acute renal failure requiring dialysis.

Investigations revealed:

Renal biopsy: crescentic glomerulonephritis

Which one of the following antibodies is most likely to be found in the blood?

- 1- Anticardiolipin
- 2- Anticentromere
- 3- Antimitochondrial
- 4- Antimyeloperoxidase
- 5- Antinuclear

Answer & Comments

Answer: 4- Antimyeloperoxidase

This patient manifests a pulmonary renal syndrome which is most commonly due to an ANCA positive vasculitis and less commonly due to Goodpasture's syndrome(anti GBM antibodies). ANCA antibodies are of 2 types:

" C-ANCA which correlates with antiproteinase 3 antibodies (PR3)

" P-ANCA which correlates with antimyeloperoxidase antibodies. P-ANCA/MPO antibodies are highly sensitive and specific for rapidly progressive glomerulonephritis and haemorrhagic alveolar capillaritis.

Antimitochondrial antibodies are found in primary billiary cirrhosis.

Anticentromere antibodies are found in CREST /Scleroderma syndrome.

ANA and anticardiolipin antibodies are found in SLE which is not a cause of pulmonary renal syndrome.

[Q: 1135] OnExamination -
Nephrology

A 65-year-old male patient is admitted with renal failure and is diagnosed with acute tubular necrosis.

Which of the following is least likely to be the cause of acute tubular necrosis?

- 1- Rhabdomyolysis
- 2- Paracetamol poisoning
- 3- Hypovolaemia
- 4- Hypertension
- 5- Corticosteroid therapy

Answer & Comments

Answer: 5- Corticosteroid therapy

Renal failure from ATN occurs in 25% patients with severe hepatic damage. Accelerated hypertension can cause small vessel obstruction, with proliferative endarteritis of intralobular arteries and fibrinoid necrosis of afferent arterioles and glomerular capillary tuft. Corticosteroid therapy has not been associated with ATN. Other causes of ATN include hypotension, hepatic failure, eclampsia and drugs such as aminoglycosides, Cephalosporins, Cisplatin, Amphotericin.

[Q: 1136] OnExamination -
Nephrology

A 45-year-old lady presents with fatigue and has established End Stage Renal Failure. She has been on haemodialysis for the past three years and receives dialysis for 3 hours three times a week at a regional haemodialysis centre.

At one of her regular visits for haemodialysis she is found to have the following observations and investigations.

Blood Pressure 170/95

serum K⁺ 5.7 mmol/L (3.5 - 4.9)

serum corrected calcium 2.0 mmol/L (2.2 - 2.6)

Hb 9.0 g/dl (11.5 - 16.5)

Creatinine 1300 mmol/l

Post-dialysis her Blood Pressure is recorded as 160/95.

Which of the following is the best management for this lady?

- 1- increase dialysis hours
- 2- treat anaemia with erythropoietin
- 3- treat hyperkalaemia
- 4- treat hypocalcaemia
- 5- treat hypertension with ramipril

Answer & Comments

Answer: 2- treat anaemia with erythropoietin

This person's main complaints are of fatigue. Treating her with erythropoietin would therefore be the most appropriate therapy particularly with her anaemia. Increasing dialysis is unlikely to be acceptable to most patients and renal units though this is an option some patients would choose, especially those on 'home haemodialysis'. Vascular disease is an important cause of death in dialysis patients and this lady may very well need additional treatment of blood pressure.

[Q: 1137] OnExamination -
Nephrology

A 63-year-old male recently admitted with sepsis is noted to have a urine output of approximately 20 mls per hour.

The oliguria is more likely to be due to prerenal failure than intrinsic renal failure if:

- 1- A urine free of red blood cells or casts
- 2- A urine:plasma urea ratio <3
- 3- urine osmolality <350 mOsm/l
- 4- a blood pressure of 150/90 and good tissue perfusion.
- 5- urinary sodium >10mmol/l

Answer & Comments

Answer: 1- A urine free of red blood cells or casts

Oliguria defined as <400ml urine/day. Red cell casts present in acute glomerulonephritis, renal vasculitis, accelerated hypertension and interstitial nephritis. Pre-renal failure is renal dysfunction due to hypoperfusion (urinary sodium <20, urine osmolality >500, urine/plasma ratio >8, and urine/plasma creatinine >40) and acute tubular necrosis is acute renal failure due to circulatory compromise and/or nephrotoxins (urinary sodium >40, urine osmolality <350, urine/plasma ratio <3, and urine/plasma creatinine <20).

[Q: 1138] OnExamination - Nephrology

In chronic untreated renal failure which of the following findings is characteristic?

- 1- Metabolic alkalosis
- 2- Hypokalaemia
- 3- Hyperosmolar dehydration
- 4- Hypercalcaemia
- 5- Hypercalcinuria

Answer & Comments

Answer: 5- Hypercalcinuria

Major pathophysiological abnormalities of chronic renal failure:

" Accumulation of nitrogenous waste products.

" Acidosis: bicarbonate wasting, decreased ammonia secretion, decreased acid excretion.

" Sodium wasting: solute diuresis, tubular damage.

" Sodium retention: Nephrotic Syndrome, CCF, anuria, excess sodium intake.

" Urinary concentrating defect: nephron loss, solute diuresis.

" Hyperkalaemia: decreased GFR, acidosis, hyperaldosteronism.

" Renal osteodystrophy: decreased intestinal calcium absorption, impaired 12-dihydroxy Vitamin D production, secondary hyperparathyroidism.

" Growth retardation: protein calorie deficiency, renal osteodystrophy, acidosis, anaemia.

" Anaemia: decreased erythropoietin production, low grade haemolysis, inadequate intake.

" Bleeding tendency: thrombocytopenia, decreased platelet function.

" Infection: defective granulocyte function.

" Neurology: uraemia, aluminium toxicity results in fatigue, poor concentration, headache, memory loss, slurred speech, muscle weakness and cramps, seizures and coma.

" GI ulceration: gastric acid hypersecretion.

" Hypertension: sodium and water overload, hyperammonaemia.

" Hypertriglyceridaemia: decreased plasma lipoprotein lipase activity.

" Pericarditis and cardiomyopathy: cause unknown.

" Glucose intolerance: tissue insulin resistance.

[Q: 1139] OnExamination -
Nephrology

34-year-old female presents with shortness of breath. She has been treated for Asthma by her GP with an inhaled steroid, but the GP has documented an eosinophilia of $1.1 \times 10^9/L$ (14%) (Normal $<0.1 \times 10^9/L$). She has been referred to the clinic because her GP found her creatinine to be $347 \mu\text{mol/l}$ ($60\text{--}110\mu\text{mol/l}$).

Which of the following would support a diagnosis of Churg-Strauss syndrome?

- 1- Extravascular eosinophils on vascular biopsy
- 2- Fixed pulmonary infiltrates on chest radiographs
- 3- Peak flow $<150\text{ml/minute}$
- 4- Peripheral alveolar filling infiltrate predominantly in the upper lobes on a chest radiograph
- 5- Peripheral "stocking" neuropathy

Answer & Comments

Answer: 1- Extravascular eosinophils on vascular biopsy

A diagnosis of Churg-Strauss syndrome requires four of the following features: asthma, eosinophilia greater than 10%, mononeuropathy or polyneuropathy, paranasal sinus abnormality, non-fixed pulmonary infiltrates visible on chest radiographs and blood vessels with extravascular eosinophils. Peripheral alveolar filling infiltrate predominantly in the upper lobes on a chest radiograph is typical of chronic eosinophilic pneumonia. A peripheral "stocking and glove" neuropathy is not typical of Churg-Strauss syndrome and is more common in type 2 diabetes.

[Q: 1140] OnExamination -
Nephrology

A 16 year-old female presents with ankle swelling 4 days after having had a sore throat. On examination she had a blood pressure of $125/80 \text{ mmHg}$ and ankle oedema. Investigations reveal:

creatinine $90 \mu\text{mol/L}$ ($50\text{--}100$)

albumin 25 g/L ($37\text{--}45$)

24 hour urinary protein 9 g (<0.2)

What is the most likely diagnosis?

- 1- idiopathic membranous nephropathy
- 2- IgA nephropathy
- 3- membranoproliferative glomerulonephritis
- 4- minimal change nephropathy
- 5- post-streptococcal glomerulonephritis

Answer & Comments

Answer: 2- IgA nephropathy

Idiopathic membranous nephropathy (A) accounts for 2-5% of cases of nephritic syndrome in children, and 20-30% of cases in adults. The immune mechanism that leads to the development of membranous nephropathy is unknown. Histologically, it is characterised by diffuse thickening of the glomerular basement membrane (GBM) on light microscopy. On immunofluorescence, the thickening is caused by immune deposits of IgG and C3, on the subepithelial surface of the GBM. When not idiopathic, it is associated with AI diseases (SLE, Rheumatoid arthritis, thyroid disease), Drugs (Gold, penicillamine, captopril), Malignancy (Bronchus, breast, stomach, colon, prostate), Infections (Hep B, Syphilis, Leprosy, Filariasis), and diabetes mellitus. Membranoproliferative (or mesangiocapillary) glomerulonephritis (C) can be classed into three types (I, II, and III) depending on which complement pathway is activated. It is associated with SLE, cryoglobulinaemia with or without Hep C,

chronic infections (SBE) or with neoplasms. It is not associated acutely with upper respiratory tract infections. Minimal change nephropathy (D) is the most common form of nephrotic syndrome in children. The histological findings on light microscopy are normal or small looking glomeruli. On electron microscopy there is effacement of the epithelial cell foot processes over the outer surface of the GBM. It tends to be steroid responsive in children, but over 60% of children will have further relapses. In adults, it is associated with Hodgkins lymphoma, and other carcinomas. Post streptococcal GN (E) as the name implies occurs 10-14 days after an acute infection. The typical case occurs following infection with group A Lancefield streptococci (?haemolytic strep, S pyogenes) either causing pharyngitis or skin infections. It is more common in the developing world. The histology shows diffuse proliferative GN, with infiltration by neutrophil polymorphs. The main treatment is eradication of the infection (10/7 course of penicillin) and symptomatic relief of the acute nephritis. The need for dialysis is uncommon, and complete recovery of renal function should occur. The correct answer is IgA nephritis (B). IgA nephritis is most common during the second and third decade of life. It commonly occurs within two days of an onset of an upper respiratory tract infection, or less commonly infection of other mucous membranes (e.g. GI, Bladder, Breast). It should be diagnosed by a renal biopsy, where IgA is seen deposited in the mesangium. The treatment of IgA nephritis is variable. In a patient with haematuria only, the treatment is conservative. When there is nephrotic range proteinuria (>3g/day- as in this case) an 8-12 week course of prednisolone should be prescribed. If the proteinuria is <3g/day an ACE inhibitor can be used. In all patients, careful control of blood pressure should be achieved, by using ACE inhibitors in the first instance, and regular follow up of renal function and urinalysis. 30% of children will have a spontaneous remission

within 10 years, but 25% will go on to develop ESRF within 20 years.

[Q: 1141] OnExamination -
Nephrology

A 16-year-old girl presented to the nephrology clinic with a four-day history of steadily increasing generalised oedema. There was no past history of note. On examination she weighed 45kg. Her blood pressure was 90/55 mmHg.

Investigations revealed:

Serum creatinine 55 umol/L

Serum albumin 20 g/L

24 hour urinary protein excretion 4.8g (<0.2g)

Ultrasound scan of kidneys Normal

If this patient is treated with prednisolone (1mg/kg for 6 weeks), what are the chances of her disease going into complete remission?

- 1- <20%
- 2- 20-39%
- 3- 40-59%
- 4- 60-80%
- 5- >80%

Answer & Comments

Answer: 2- 20 ?39%

This girl has probably developed idiopathic glomerulonephritis, which accounts for 90% of all childhood cases of the nephrotic syndrome. The main cause is minimal change nephrotic syndrome.

The first line treatment for minimal change nephropathy is prednisolone for 4-6 weeks (60mg/m²) reducing to 40mg/m² for a further 4-6 weeks. With this treatment 93% of children will respond with complete loss of proteinuria within 8 weeks. However, once remission is induced, 66% of children will have at least one relapse (34% will have complete remission). Between 40 and 55% of children

affected, who initially respond to steroids will develop multiple relapses when the steroids are reduced. Early, frequent relapses (3 or more in the first 6 months) signify a relapsing course, and requires treatment with cyclophosphamide.

[Q: 1142] OnExamination -
Nephrology

A 42-year-old female with a recent diagnosis of systemic sclerosis, is referred to hospital with a complaint of headaches and blurred vision. She has a past medical history of asthma. On examination, her blood pressure is 230/120, and there is bilateral papilloedema.

Which of the following medications should be prescribed immediately?

- 1- IV Furosemide
- 2- IV Labetolol
- 3- IV Sodium Nitroprusside
- 4- Oral Enalapril
- 5- Sublingual Nimodipine

Answer & Comments

Answer: 4- Oral Enalapril

Systemic sclerosis is a systemic disorder characterised by skin thickening due to the deposition of collagen in the dermis. Adverse prognostic features are renal, cardiac or pulmonary involvement. A major complication is the development of scleroderma renal crisis. This is characterised by the abrupt onset of severe hypertension, usually with retinopathy, together with rapid deterioration of renal function and heart failure. It develops in 8-15% of patients with diffuse systemic sclerosis, especially associated with rapid progression of diffuse skin disease. It usually presents early, within three years of diagnosis. The pathogenic mechanisms leading to renal damage are not known. The clinical presentation is typically with the symptoms of malignant hypertension, with headaches,

blurred vision, fits and heart failure. Renal function is impaired and usually rapidly deteriorates. The hypertension is almost always severe with a diastolic BP over 100 mmHg in 90% of patients. There is hypertensive retinopathy in about 85% of patients, with exudates and haemorrhages and if severe, papilloedema. Scleroderma renal crisis is a medical emergency. The hypertension should be treated with an ACE inhibitor. The aim is to reduce the blood pressure gradually, as an abrupt fall can lead to cerebral ischaemia or infarctions (as in any accelerated hypertension). Calcium channel blockers may be added to ACE inhibitors. Deterioration in renal function can be rapid, with gross pulmonary oedema; therefore patients with scleroderma renal crisis should be managed in hospitals with facilities for dialysis.

[Q: 1143] OnExamination -
Nephrology

A 45-year-old man with chronic renal failure presents to clinic complaining of increasing fatigue and weakness. He receives three hours of haemodialysis, thrice weekly. His blood pressure is measured at 176/110 mmHg pre-dialysis and 166/95 mmHg post-dialysis.

Investigations pre-dialysis show:

Hb	9.5 g/dL
Potassium	6.9 mmol/L
Creatinine	1567 umol/L
Calcium(corrected)	2.1 mmol/L

Which of the following options is most appropriate initial management for this patient?

- 1- Give alfacalcidol to correct hypocalcaemia
- 2- Increase the duration of each dialysis session
- 3- Reduce the potassium concentration in the dialysate

- 4- Start erythropoietin to increase haemoglobin level
- 5- Start ramipril to gain better control of his blood pressure

Answer & Comments

Answer: 2- Increase the duration of each dialysis session

This patient has been poorly managed! Again the question is the issue here. What is the most appropriate management. in this case.

Pre dialysis blood pressure and blood investigations are a poor indication of dialysis adequacy.

It would be more helpful in this question to have post dialysis blood results, especially urea, which could give an idea of dialysis adequacy.

His post dialysis blood pressure is too high. It should be controlled with antihypertensive medication if the patient is achieving his dry weight with fluid ultra filtration on haemodialysis.

His haemoglobin is lower than 11g/dL, which is the minimum level a patient with end stage renal failure should have. Initially he should be treated with IV iron, and if the haemoglobin is still low, erythropoietin should be commenced.

Hyperkalaemia can cause lethargy and muscle weakness, but only if the levels are over 7mmol/L. The above potassium level is probably expected pre dialysis.

His corrected calcium is borderline low (aim for 2.2-2.6mmol/L), but should not cause the above symptoms.

This patient has non-specific symptoms. He is hypertensive post dialysis, and has a very high pre dialysis serum creatinine. He requires further management of his haemoglobin, blood pressure and calcium levels.

None of the above would cause the non-specific deterioration seen in this patient, and therefore the most appropriate management strategy that would affect most things would be increasing the dialysis adequacy, by increasing the duration of each dialysis session.

[Q: 1144] OnExamination - Nephrology

A 30-year-old woman receives a cadaveric renal transplantation after having with had renal failure with a neuropathic bladder for which she performed intermittent self-catheterisation. Six months after transplantation she presents with acute pain in the region of the transplanted kidney.

Which one of the following is the most likely reason for the pain?

- 1- Acute retention of urine
- 2- allograft rejection
- 3- pyelonephritis
- 4- renal calculi
- 5- renal infarction

Answer & Comments

Answer: 3- pyelonephritis

Acute urinary retention would not cause pain overlying a transplanted kidney, and as this lady self-catheterises, it would be an unlikely occurrence. Due to the elapsed time between the transplant and this episode, allograft rejection can be discounted. This is because chronic rejection (>3months post transplant) is a painless process, with difficult to control hypertension, proteinuria and slowly rising serum creatinine. Accelerated rejection (1-5 days post transplant) can present with fever, an acutely tender swollen graft, and rapidly rising serum creatinine. Acute rejection (5 days-3months) is clinically silent in the majority, but can present with a swollen, tender kidney. Renal infarction can also be

discounted. This can be a surgical complication of renal transplantation, but it presents early with a calyceal fistula and urinary leak. Renal stones could cause acute pain in the region of a transplanted kidney, but would be less likely in this patient than answer A. The answer in this case is acute pyelonephritis. This patient is in the intermediate stage of the post-transplantation immunosuppression, when the patient is most immunocompromised (3-6 months post-transplant). She is at high risk of an acute episode of pyelonephritis in the transplanted kidney, due to the immunosuppression, the neuropathic bladder and self-catheterisation. This would present like an acute rejection episode, with a tender swollen graft, low-grade pyrexia, and deteriorating graft function. This would be commonly associated with septicaemia in this patient, and requires parenteral antibiotics. If this lady was to be managed as a transplant rejection, with high dose IV steroids, the result could be catastrophic.

[Q: 1145] OnExamination -
Nephrology

A 60-year-old man wishes to act as a kidney donor to his 37-year-old wife. She has end-stage renal failure from polycystic kidney disease and is maintained on peritoneal dialysis. The couple have two teenage daughters, neither of whom have renal cysts on recent ultrasound scans.

Which one of the following statements is correct?

- 1- Living related donation from one of the daughters would be preferable to donation from the husband
- 2- Living unrelated donation is not recommended in cases of inherited renal disease
- 3- The age difference between husband and wife is a relative contraindication to transplantation

- 4- The husband should not be accepted for kidney donation until all siblings have been considered
- 5- The results of living unrelated kidney donation are sufficiently poor that organ donation should not proceed

Answer & Comments

Answer: 4- The husband should not be accepted for kidney donation until all siblings have been considered

Providing there is a sibling who is proven not to have polycystic kidney disease, living related donation should be considered as this would ensure a better match and better graft survival. As teenagers polycystic kidney disease may not be manifest ultrasonographically in her daughters. Living unrelated kidney donation does not produce bad results. In patients with polycystic kidney disease, or for other inherited diseases, a graft from an unrelated donor would not necessarily succumb to the same disease process. Where there is a shortage of donors, the age difference certainly would not be considered a relative contraindication to kidney donation.

[Q: 1146] OnExamination -
Nephrology

A 45-year-old man had recurrent nephrolithiasis. Renal function tests and serum calcium measurements were normal. A 24 hour urine collection revealed:

volume 3L

calcium 15 mmol/24 hours (2.5 - 7.5)

oxalate 200 mmol/24 hours (90 - 450)

uric acid 3 mmol/24 hours (1.48 - 4.45)

citrate 2mmol/24hours(0.3-3.4)

What is the most useful therapy to reduce stone formation?

- 1- allopurinol

- 2- dietary calcium restriction
- 3- penicillamine
- 4- potassium citrate
- 5- thiazide diuretic

Answer & Comments

Answer: 5- thiazide diuretic

This patient has hypercalciuria and thiazide diuretics can decrease urinary excretion of calcium and possibly oxalate. Dietary calcium restriction will not limit calciuria, given the large amount of calcium that can be mobilised from bone. The lack of hyperuricosuria and hypocitraturia excludes the other treatments offered.

[Q: 1147] OnExamination - Nephrology

A 14-year-old old boy presents with a sore throat and macroscopic haematuria.

What would light microscopy of a kidney biopsy most likely show?

- 1- Crescentic glomerulonephritis
- 2- Collapsed glomeruli
- 3- Mesangial hypercellularity
- 4- Segmental sclerosis
- 5- Normal tissue

Answer & Comments

Answer: 3- Mesangial hypercellularity

The most common cause of macroscopic haematuria in a child is IgA nephritis.

This usually develops 1-2 days after a sore throat. It is most common in the second and third decades of life, and is three times more common in males.

The urine may be frankly bloody, or may be the colour of cola. There are no clots in the urine, and the haematuria is generally

painless, although some patients complain of mild loin pain.

It tends to settle spontaneously within 5 days, although the episodes may be recurrent, lasting for one to two years.

Renal biopsy will show mesangial IgA deposition on immunofluorescence, and light microscopy will show mesangial hypercellularity and matrix expansion.

[Q: 1148] OnExamination - Nephrology

A 37-year-old woman underwent a kidney transplant which never functioned. A biopsy revealed pathological features consistent with acute rejection associated with anti-HLA antibodies.

Which type of immunoglobulin is expected to account for this process?

- 1- Ig D
- 2- Ig A
- 3- Ig E
- 4- Ig G
- 5- Ig M

Answer & Comments

Answer: 4- Ig G

This acute rejection is recognised and due to anti-IgG antibodies to the HLA incompatible tissues with primary activation of T cells. The acute response is treated with immunosuppressants.

[Q: 1149] OnExamination - Nephrology

Metastatic calcification in chronic renal failure:

- 1- unaffected by time on CAPD
- 2- rapidly reversed in all sites after parathyroidectomy

- 3- characteristically caused by calcium oxalate deposition
- 4- increased prevalence with time on haemodialysis
- 5- decreased by Vitamin D

Answer & Comments

Answer: 4- increased prevalence with time on haemodialysis

CRF associated with low serum calcium, hyperphosphataemia, increased PTH, reduced intestinal calcium absorption and raised alkaline phosphatase. Parathyroidectomy improves extraskelatal calcification, but vascular calcification improves less than periarticular calcification. Metastatic calcification due mainly to calcium phosphate deposition, although CRF managed with dialysis is the commonest cause of secondary oxalosis (acute arthritis of small joints with digital calcific deposits). Prolonged treatment with Vitamin D (hence hypercalcaemia and hyperphosphataemia) increases extraskelatal calcification.

[Q: 1150] OnExamination - Nephrology

A 17-year-old woman underwent a renal transplant. She was concerned about the effects of long-term Cyclosporin treatment.

Which one of the following is a common adverse effect of this drug?

- 1- Alopecia
- 2- Bone marrow depression
- 3- Hepatotoxicity
- 4- Nephrotoxicity
- 5- Paraesthesiae

Answer & Comments

Answer: 4- Nephrotoxicity

Cyclosporin causes hypertrichosis rather than alopecia and the most frequent adverse side effect of this drug is nephrotoxicity. Post renal transplant, the 2 most common causes of declining renal function are graft rejection and cyclosporin toxicity. Hepatotoxicity, paraesthesia are less common side effects of the drug.

[Q: 1151] OnExamination - Nephrology

In which of the following circumstances would the treatment of anaemia with erythropoietin still be expected to be effective?

- 1- Aluminium toxicity
- 2- Folate deficiency
- 3- Hyperkalaemia
- 4- Infection
- 5- Iron deficiency

Answer & Comments

Answer: 3- Hyperkalaemia

Epoetin (recombinant human erythropoietin) is used in chronic renal failure, to shorten the period of anaemia in those receiving platinum-based chemotherapy and prevention of anaemia in premature babies with low birth weight. Its efficacy may be impaired in certain circumstances particularly with iron deficiency but also with aluminium toxicity, folate deficiency and infection. In the latter, the switch to the acute phase proteins impairs its function. Its efficacy is unimpaired in hyperkalaemia.

[Q: 1152] OnExamination - Nephrology

A 23 year-old female presents at 16 weeks into her first pregnancy with a blood pressure of 144/96 mmHg. A 24 hour urine collection reveals a protein excretion of 0.7 g/d

What is the most likely explanation for these findings?

- 1- Essential hypertension
- 2- Gestational hypertension
- 3- Normal changes of pregnancy
- 4- Pre-eclampsia
- 5- Secondary hypertension

Answer & Comments

Answer: 5- Secondary hypertension

This pregnant woman has hypertension and proteinuria (as defined by a blood pressure above 140/90 and proteinuria above 0.3 g/d). It would not be regarded as normal to have this high a blood pressure or protein content of urine. Pre-eclampsia is a disease occurring in the second half of pregnancy (after 20 weeks gestation), and conventionally, characterised by pregnancy-induced hypertension, with proteinuria and often with oedema. Gestational hypertension is defined as blood pressure elevation detected for the first time after midpregnancy, without proteinuria. Essential hypertension is unlikely in this female as there is a suggestion of renal disease which makes, secondary hypertension the likely option.

[Q: 1153] OnExamination - Nephrology

A 60-year-old male presents with typical renal colic and one day later passes a small stone. However, the original X-ray of the abdomen revealed no obvious calculi.

What is the most likely composition of his calculus?

- 1- Calcium
- 2- Cystine
- 3- Oxalate
- 4- Phosphate
- 5- Uric acid

Answer & Comments

Answer: 5- Uric acid

The main constituent will be uric acid.

Major causes of stone formation:

" Calcium stones (80%) - hypercalciuria (e.g. primary hyperparathyroidism), hyperoxaluria (e.g. XS intake, ileal disease and bypass)

" Uric acid stones (10%) - high purine intake, high cell turnover

" Cystine stones (2%) - cystinuria (AR defect in dibasic amino acid transporter)

" Infection stones (5%) - chronic infection with urea splitting organisms causes stones made of magnesium ammonium phosphate and calcium phosphate

" Other stones (3%) - include xanthine stones, rare renal chloride channel mutations can cause stone formation

There appears to be a male predominance with a 2:1 ratio.

Calcium and infection stones are radio-opaque, cystine stones are weakly radio-opaque and urate stones are radiolucent.

[Q: 1154] OnExamination - Nephrology

A 68-year-old male is referred by his general practitioner with deteriorating hypertension and renal function.

Investigations show:

Serum creatinine 250 µmol/L (NR 60 - 110)

Urinalysis + protein

Renal ultrasound scan: left kidney 9cm long right kidney 7cm, no obstruction (10 - 12cm)

Which of the following would be the most appropriate investigation for this patient?

- 1- intravenous renography
- 2- isotope renography

- 3- MR angiography
- 4- renal biopsy
- 5- retrograde pyelography

Answer & Comments

Answer: 3- MR angiography

The diagnosis is likely to be atherosclerotic renal artery stenosis as suggested by the asymmetric reduction in renal size, with mild proteinuria quite common in the condition. Investigations include Captopril Renography, MR angiography which is virtually as good as renal arteriography. None of the other investigations are appropriate for RAS.

[Q: 1155] OnExamination - Nephrology

A 58-year-old man with longstanding hypertension was found to have a serum creatinine concentration of 275 micromol/L (60 - 110). Urinalysis showed blood ++ and protein >1 g/L. Renal ultrasound showed the left kidney to be 9.2 cm long, the right to be 8.9 cm long (normal range for both kidneys 10-12 cm), and neither kidney was obstructed.

What is the best investigation to diagnose the cause of the renal impairment?

- 1- intravenous urography
- 2- isotope renography
- 3- renal arteriography
- 4- renal biopsy
- 5- retrograde pyelography

Answer & Comments

Answer: 4- renal biopsy

The presence of long standing hypertension, haematuria, significant, non, nephrotic proteinuria is highly suspicious of glomerular pathology, such as IgA nephropathy which is best characterised by a renal biopsy. In the absence of obstruction on ultrasound,

intravenous urography, retrograde pyelography, and isotope renography are not appropriate. Renal size asymmetry in the presence of hypertension and renal impairment might prompt the search for renovascular disease. However, in this case of kidneys are of similar and good size.

[Q: 1156] OnExamination - Nephrology

A 30-year-old male presents with oedema and proteinuria. On examination his blood pressure was 120/70 mmHg. Investigations reveal:

Creatinine 88 umol/L (60-110)

Albumin 25 g/L (37-49)

Urinalysis no blood

protein ++++

Urinary protein excretion 7g/24hr (<0.2)

Ultrasound of renal tract normal right kidney, absent left kidney

Which is the most appropriate course of action for this patient?

- 1- Albumin transfusion
- 2- Angiotensin converting enzyme inhibitor therapy
- 3- High protein diet
- 4- Renal biopsy
- 5- Trial of steroid therapy

Answer & Comments

Answer: 5- Trial of steroid therapy

This patient has Nephrotic syndrome, which is a combination of:

- " Proteinuria (usually > 3g/24 hrs)
- " Hypoalbuminaemia (<35g/L)
- " Oedema
- " Hyperlipidaemia

The most appropriate course of action here would be to undergo a trial of steroid therapy. Ideally a renal biopsy would be indicated to determine the cause of the nephrotic syndrome, however as this patient only has 1 kidney then this would be considered a relative contraindication for such a procedure. A high protein diet / albumin transfusion would be of little to no benefit - and the latter would need to be salt poor. ACE - inhibitors reduce proteinuria and slow deterioration in GFR. In this case given the patients age he may well have minimal change GN (commonest in children) - which is normally steroid responsive. In the young adult histological diagnoses are in general: Minimal change > Mesangiocapillary > FSGS > Lupus > Membranous > Diabetes. In general steroids are tried first and then 2nd line agents such as cyclosporin and cyclophosphamide are introduced if needed.

[Q: 1157] OnExamination - Nephrology

A 49-year-old woman has been an inpatient for the past 10 days for treatment of a bronchopneumonia. She has developed the onset of chills, fever, and skin rash over the past two days. A peripheral blood film reveals eosinophilia. On urinalysis she has ++ proteinuria. There is no past history of renal disease. Her hemoglobin A1C is normal.

These findings would most strongly suggest which of the following diagnoses?

- 1- Acute serum sickness
- 2- Acute tubular necrosis
- 3- Drug-induced interstitial nephritis
- 4- IgA nephropathy
- 5- Post-streptococcal glomerulonephritis

Answer & Comments

Answer: 3- Drug-induced interstitial nephritis

The findings are typical of a drug-induced acute interstitial nephritis. Post-streptococcal GN appears weeks after the acute infection. Berger's disease (IgA nephropathy) is characterized by hematuria and often follows a 'flu-like' illness. Eosinophilia is not typical for serum sickness.

[Q: 1158] OnExamination - Nephrology

A 45-year-old man on regular haemodialysis complained of weakness and exertional fatigue. On examination, his blood pressure was 170/105 mmHg (pre-dialysis) and 160/95 mmHg (post-dialysis). Investigations pre-dialysis revealed:

Haemoglobin 9.0g/dl
 serum potassium 6.9
 serum creatinine 1250
 serum corrected calcium 2.1 mmol/l

Which intervention is most likely to improve his symptoms:

- 1- increase haemoglobin with epoetin
- 2- increase the length of each dialysis session
- 3- lower the potassium in the dialysate
- 4- improve blood pressure control with ramipril
- 5- correct hypocalcaemia with alfacalcidol

Answer & Comments

Answer: 1- increase haemoglobin with epoetin

This is a tough question with many possible answers. But and importantly, this question asks: how to improve his symptoms! Changing the question round such as how to improve blood pressure or how to improve prognosis alters the answer.

There are several deficiencies in the management of this patient with end stage renal failure. The symptoms described are more in keeping with his anaemia. A mild

hypocalcaemia and hyperkalaemia would not give rise to his symptoms. This also applies to his uncontrolled hypertension. His predialysis creatinine implies he is underdialysed but would not give rise to exertional fatigue. Bearing in mind all the above, the question specifically asks what intervention would improve his symptoms. In which case one would have to elect EPO irrespective of blood pressure, calcium etc.

[Q: 1159] OnExamination -
Nephrology

Which one of the following statements is correct?

- 1- adult polycystic renal disease is inherited as an autosomal recessive trait
- 2- reflux nephropathy is inherited as an autosomal recessive trait
- 3- nephrogenic diabetes insipidus is inherited as an autosomal dominant trait
- 4- Alport's syndrome affects females more severely than males
- 5- medullary sponge kidney is typically not inherited but is a congenital condition.

Answer & Comments

Answer: 5- medullary sponge kidney is typically not inherited but is a congenital condition.

PKD is usually autosomal dominant although the infantile form is autosomal recessive. Nephrogenic DI is usually X-linked. Features of Alport syndrome (hereditary nephritis, haematuria, progressive renal failure and high-frequency nerve deafness) are usually more marked in males. Neither reflux nephropathy nor medullary sponge kidneys are hereditary conditions.

[Q: 1160] OnExamination -
Nephrology

A 28-year-old man presented with

hypertension. On examination he had palpable kidneys and abdominal ultrasound shows bilaterally enlarged cystic kidneys.

Which one of the following conditions is most likely to be present in this patient?

- 1- Mitral stenosis
- 2- Nail dystrophy
- 3- Polycythaemia
- 4- Short stature
- 5- Testicular atrophy

Answer & Comments

Answer: 3- Polycythaemia

The most likely diagnosis here is adult polycystic kidney disease, which is associated with valvular heart abnormalities, incompetence and aneurysms of the cerebral circulation.

However, it is also associated with excessive Erythropoietin production and polycythaemia

[Q: 1161] OnExamination -
Nephrology

A 32-year-old female is diagnosed with Goodpasture's syndrome.

Which of the following therapies used in conjunction with plasmapheresis and corticosteroids would be expected to improve prognosis associated with the condition?

- 1- Azathioprine
- 2- Cyclosporin
- 3- Cyclophosphamide
- 4- Mycophenolate mofetil
- 5- Tacrolimus

Answer & Comments

Answer: 3- Cyclophosphamide

Studies reveal that without treatment, mortality is as high as 90% in association with

Goodpasture's. However, the prognosis is drastically improved with the removal of antigen through plasmapheresis, immunosuppression with corticosteroids and cyclophosphamide. There are some studies revealing the potential of mycophenolate mofetil but the evidence is rather anecdotal.

[Q: 1162] OnExamination - Nephrology

A 32-year-old male is referred with chronic renal dysfunction and is discovered to have Adult Polycystic Kidney Disease. His blood pressure is consistently 140-150/90 mmHg.

Which of the following antihypertensives is the most appropriate for the management of this man's blood pressure?

- 1- ACE inhibitor
- 2- Betablocker
- 3- Calcium channel blocker
- 4- Diuretic
- 5- Moxonidine

Answer & Comments

Answer: 1- ACE inhibitor

Autosomal dominant APKD-1 is a relatively common disorder accounting for approx 8% of cases of ESRD. "The best drugs for this condition are ACE inhibitors (ie, captopril, enalapril, lisinopril) or angiotensin II receptor antagonist blockers (ie, telmisartan, losartan, irbesartan, candesartan). Calcium channel blockers are not encouraged to be used."

However, although widely used and recommended, there is no evidence that the renin-angiotensin system is affected in the disease.

[Q: 1163] OnExamination - Nephrology

A 25-year-old female is admitted with acute dyspnoea and chest pain. A diagnosis of

pulmonary embolism is confirmed and her investigations reveal urine dipstick protein ++ but no blood, anti-double stranded DNA antibodies of 200 U/mL (0 - 73), with a 24 hour urinary protein concentration of 5g (< 0.2).

Which one of the following diagnoses is most likely to be found on renal biopsy?

- 1- AA amyloid
- 2- Focal segmental glomerulonephritis
- 3- IgA nephropathy
- 4- membranous nephropathy
- 5- minimal change nephropathy

Answer & Comments

Answer: 4- membranous nephropathy

This young woman has thromboembolic disease, the nephrotic syndrome with positive anti-ds DNA antibodies suggests a diagnosis of SLE. Nephrotic syndrome in the absence of hypertension, active urinary sediment, or significant hypocomplementemia suggests membranous nephropathy. The thromboembolic disease may arise due to nephrotic syndrome per se or from an associated antiphospholipid syndrome.

[Q: 1164] OnExamination - Nephrology

A 25-year-old woman who is 20 weeks pregnant is diagnosed with pyelonephritis. She had suffered recurrent urinary infections since childhood and her family history reveals that her mother had a history of hypertension and had been told she had a kidney problem. Examination was normal and Urea and Creatinine were both normal

What is the most likely diagnosis?

- 1- autosomal dominant polycystic kidney disease
- 2- bladder outlet obstruction

- 3- normal physiological urinary stasis of pregnancy
- 4- reflux nephropathy
- 5- renal stone disease

Answer & Comments

Answer: 5- renal stone disease

This lady has had recurrent urinary tract infections since childhood, and now presents with pyelonephritis. Pyelonephritis is an uncommon infection in pregnancy, and requires aggressive treatment with antibiotics. It is associated with preterm labour in 4% and may lead to foetal distress. The answer is not ADPKD (A), as symptoms do not tend to occur before the age of 40. Bladder outlet obstruction (B) should not occur in pregnancy, and would cause hydronephrosis and worsening renal function. Answer C is incorrect, as this should not cause pyelonephritis. Renal stone disease (E) does predispose to developing urinary tract infections, but is less likely than reflux nephropathy. The correct answer is reflux nephropathy (D). This lady has a long history of urinary tract infections, with probable underlying reflux scarring and this would predispose her to developing pyelonephritis in pregnancy.

[Q: 1165] OnExamination - Nephrology

Which of the following is a known risk factor for the development of chronic rejection of kidney transplantation :-

- 1- Age
- 2- Anti-smooth muscle antibodies
- 3- Presence of anti-HLA antibodies
- 4- Smoking
- 5- Toxoplasma infection

Answer & Comments

Answer: 3- Presence of anti-HLA antibodies

Chronic rejection is characterised by fibrosis of normal organ structures. The pathogenesis of chronic rejection is not clear- some prefer the term "chronic allograft dysfunction" since both immunological (antigen-dependent and antigen-independent) and non-immunological factors have been identified.

Cell-mediated and humoral immune mechanisms have been implicated in this form of graft rejection. It has also been suggested that rejection is a response to chronic ischaemia caused by injury to endothelial cells. Proliferation of intimal smooth muscle is observed leading to vascular occlusion. The fact that chronic rejection is rare in transplants between HLA-identical siblings suggests that HLA-antigen dependent immunological factors are important. Risk factors include: number of previous acute rejection episodes, presence of anti-HLA antibodies, anti-endothelial antibodies, CMV infection, dyslipidaemia, hypertension, functional mass of the donor kidney and delayed graft function (a clinical manifestation of ischaemia/reperfusion injury)

[Q: 1166] OnExamination - Nephrology

A 60-year-old man presents with right foot drop, left foot and left hand numbness, fever, malaise, weight loss, polymyalgia and polyarthralgia of approximately one month duration.

On examination, he appears unwell ill, with a temperature of 38.5 C and blood pressure of 180/100 mmHg.

Investigations reveal:

haemoglobin 8.0 g/dL (13-18)

erythrocyte sedimentation rate 100 mm/hr (0-20)

serum creatinine 180 µmol/L (60-100)

Urine analysis blood ++

urine microscopy: white cells and red cell casts

Which one of the following is the most likely diagnosis?

- 1- antiphospholipid syndrome
- 2- giant cell arteritis
- 3- paraneoplastic syndrome
- 4- POEMS syndrome
- 5- polyarteritis nodosa

Answer & Comments

Answer: 5- polyarteritis nodosa

This patient has a mononeuritis multiplex, fever, hypertension, and nephritic renal involvement suggesting a diagnosis of PAN. POEMS is a polyneuropathy, organomegaly, endocrinopathy and Myeloma of which a few features are absent and nephritic syndrome is not a feature.

[Q: 1167] OnExamination - Nephrology

Which of the following is associated with Hyperuricaemia?

- 1- is usually due to an excess purine consumption
- 2- occurs in association with acute lymphoblastic leukaemia
- 3- in primary gout is inherited in an autosomal dominant manner
- 4- can be reduced with low dose aspirin therapy
- 5- can be treated with uricosuric drugs even in renal failure

Answer & Comments

Answer: 2- occurs in association with acute lymphoblastic leukaemia

Hyperuricaemia may be due to increased purine intake, urate production or reduced

urate clearance, and is most commonly due to the latter. Therefore it can occur in association with enhanced cell destruction particularly leukaemias. Primary gout has no obvious mode of inheritance, but familial juvenile gouty nephropathy is an autosomal dominantly inherited disorder. Low dose aspirin may exacerbate gout but high dose aspirin is uricosuric. Many of the uricosuric drugs may be detrimental in renal failure and may not be effective.

[Q: 1168] OnExamination - Nephrology

A 60-year-old man was diagnosed last year with adenocarcinoma of the lung, and a 4 cm mass lesion was treated with a right lower lobectomy. He now has an abdominal CT scan that reveals scattered hepatic mass lesions and hilar lymphadenopathy. For several weeks, he has had increasing malaise.

Urinalysis Protein +++

24 hour urine protein 2.7 g/24hr

serum urea 30 mmol/L (2.5 - 7.5)

serum creatinine 450 µmol/L (60 - 110)

A renal biopsy shows focal deposition of IgG and C3 with a granular pattern.

What is the most likely diagnosis?

- 1- Goodpasture's syndrome
- 2- Membranous glomerulonephritis
- 3- Minimal change glomerulonephritis
- 4- Nodular glomerulosclerosis
- 5- Rapidly progressive glomerulonephritis

Answer & Comments

Answer: 2- Membranous glomerulonephritis

Most cases of membranous GN are idiopathic, but in some patients there is a history of an infection or a malignancy (usually lung) with antigenemia.

[Q: 1169] OnExamination -
Nephrology

A 25-year-old female wishes to start a family but she is concerned as her 50-year-old mother had adult polycystic kidney disease. Examination reveals no specific abnormalities.

Which is the most appropriate screening test for polycystic kidney disease in this woman?

- 1- Genetic linkage analysis
- 2- Intravenous urogram
- 3- Isotope renography
- 4- Renal ultrasound
- 5- Urinalysis

Answer & Comments

Answer: 4- Renal ultrasound

The answer lies between renal ultrasound and genetic linkage analysis. Polycystic kidney disease is an autosomal dominant disorder. Mutations in at least 3 different genes can lead to autosomal dominant polycystic disease (APKD).

" PKD-1 on chromosome 16: 85% of cases: - polycystin 1 is an integral membrane glycoprotein involved in cell / matrix interactions.

" PKD-2 on chromosome 4: 10% of cases: - polycystin 2 which may associate with polycystin 1 through a common signalling pathway.

" A third gene mutation is known but its exact chromosomal location is not.

Diagnosis is made by multiple bilateral renal cysts and a positive family history.

1. Genetic linkage studies: can exclude or make the diagnosis in younger patients. Requires blood from at least 2 affected family members.

2. Ultrasonography: in PKD 1 families, age related diagnostic criteria are used: - 2 cysts in < 30 years age group.

3. At least 2 cysts in each kidney in 30 - 59 years. 4 cysts in each kidney for > 60 years.

4. CT: more sensitive than USS and may aid in diagnosis in younger patients.

5. MR Angiography: in patients with a FHx of intracranial aneurysm - to screen for cerebral aneurysms.

[Q: 1170] OnExamination -
Nephrology

A 65-year-old man presents with renal colic. The following day he passes a stone in his urine with analysis revealing that it is composed of uric acid.

Which one of the following is the most likely cause of this type of renal stone?

- 1- Allopurinol
- 2- chronic renal failure
- 3- Primary hyperparathyroidism
- 4- thiazide diuretics
- 5- secondary polycythaemia

Answer & Comments

Answer: 4- thiazide diuretics

Uric acid stones occur in 5-25% of all cases of nephrolithiasis. They are associated with hyperuricaemia and hyperuricosuria. Predisposing factors for uric acid stone formation are dehydration, high purine load (high protein diet), as a primary factor in idiopathic gout, and associated with high cell turnover (e.g. haematological malignancy). Chronic renal failure (B) is incorrect, as there is hyperuricaemia without hyperuricosuria. Hyperparathyroidism (C) is associated with calcium stones, not uric acid stones. Primary polycythaemia would predispose to uric acid stone formation, whereas secondary

polycythaemia (E) does not. Allopurinol (A) is prescribed to treat gout and prevents uric acid formation; hence it reduces the frequency of uric acid stones. The correct answer is thiazide diuretics (D). Thiazide diuretics cause hyperuricaemia and can predispose to hyperuricosuria and uric acid stone formation. Uric acid stones are also associated with underlying hypertension. Thiazide diuretics are used to treat calcium stones, as they increase the reabsorption of calcium from the proximal tubules, preventing hypercalciuria.

[Q: 1171] OnExamination - Nephrology

A 52-year-old man has been referred to the renal clinic due to deteriorating renal function. A diagnosis of adult polycystic kidney disease is made. His family history reveals that his mother died of a stroke at the age of 50 and his father is still alive.

He is concerned regarding the inheritance of the disorder and wishes to know what the risk to his son is of inheriting this disorder?

- 1- 0%
- 2- 25%
- 3- 50%
- 4- 75%
- 5- 100%

Answer & Comments

Answer: 3- 50%

APKD is autosomal dominant condition and typically presents between the ages of 30-50. Patients develop deteriorating renal function and associated hypertension. As well as renal cysts they may also have hepatic and berry aneurysms (maternal history may be highly relevant here). The chances of passing this condition to his son is 50%.

[Q: 1172] OnExamination - Nephrology

A 70-year-old man is admitted to hospital complaining of a twelve-day history of loin pain, fevers and occasional rigors. On examination, his temperature is 37.9°. The renal function is normal. Urinalysis of a mid stream urine shows: No organisms seen, with no growth

White Cell Count $>100 /\text{mm}^3$

Red Cell Count $> 50 /\text{mm}^3$

Which would be your first investigation of choice?

- 1- CT abdomen and pelvis
- 2- Intra Venous Urogram (IVU)
- 3- Ultrasound scan renal tract
- 4- Transthoracic echocardiogram
- 5- Prostatic Specific Antigen (PSA) measurement

Answer & Comments

Answer: 3- Ultrasound scan renal tract

Renal cell carcinomas may present in a variety of ways, with only a minority being diagnosed with the classical triad of haematuria, loin pain and a palpable mass. Relatively common presentations include anaemia, hypertension, pyrexia of unknown origin, fatigue and increased plasma viscosity. Less common presentations include hypercalcaemia, polycythaemia, liver dysfunction, enteropathy or myopathy. Urinalysis may show sterile pyuria, as here. Other causes of sterile pyuria are partially treated UTI, TB of the renal tract, urethritis and sexually transmitted diseases, acute glomerulo-nephritis, tubulo-interstitial diseases, adult polycystic kidney disease, and renal stones. Ultrasound scan of the renal tract would be the first investigation of choice, as it is able to pick up 95% of renal cell carcinomas $>1\text{cm}$ in diameter. It would also exclude infective or inflammatory collections within the renal tract. If required a CT +/-

guided biopsy could be obtained to prove the diagnosis. An IVU was considered the investigation of choice before the advent of ultrasound. A chest x-ray and bone scan would be required to complete the basic investigations.

[Q: 1173] OnExamination -
Nephrology

A 62-year-old man with a longstanding history of hypertension is seen in the outpatient clinic.

Investigations:

Creatinine 280 $\mu\text{mol/L}$

Urinalysis

Blood ++

Protein 1.8 g/L

Ultrasound scan of kidneys Left kidney 8.5 cm;
right kidney 8.9cm

What is the best investigation to diagnose the cause of his renal impairment?

- 1- Intravenous urogram (IVU)
- 2- Isotope renogram
- 3- Renal angiogram
- 4- Renal biopsy
- 5- Retrograde pyelogram

Answer & Comments

Answer: 4- Renal biopsy

This patient has a long history of hypertension; therefore it should have been appropriately controlled in the clinic.

The patient now presents with bilaterally shrunken kidneys, renal impairment and evidence of a glomerulonephritis.

In the presence of mild to moderate hypertension, proteinuria indicates either underlying renal disease or renovascular disease.

As this patient has blood and protein in the urine, on the background of impaired renal function and shrunken kidneys, the best investigation would be to perform a renal biopsy (assuming the hypertension was controlled). This would differentiate between renovascular disease and glomerulonephritis, which may be reversible.

If this patient had the above clinical findings without blood and protein in the urine, then the investigation of choice would be a renal angiogram, to diagnose renovascular disease.

[Q: 1174] OnExamination -
Nephrology

A 15-year-old girl was seen by her family physician because of increasing lethargy. She had a recent history of the "flu". Biochemistry tests show that she has renal impairment.

serum sodium 140 mmol/L (137 - 144)

serum potassium 4.2 mmol/L (3.5 - 4.9)

serum urea 28 mmol/L (2.5 - 7.5)

serum creatinine 280 $\mu\text{mol/L}$ (60 - 110)

Her condition does not improve after several weeks on corticosteroid therapy, so a renal biopsy is performed. The biopsy demonstrates the presence of segmental sclerosis of 3 of 10 glomeruli identified in the biopsy specimen. Immunofluorescence studies and electron microscopy do not reveal evidence for immune deposits.

What is the most appropriate advice to give regarding her condition?

- 1- She has an underlying malignancy
- 2- She may require a renal transplant in 10 years
- 3- She will improve if she loses weight
- 4- She will likely develop a restrictive lung disease
- 5- She will probably improve with additional corticosteroid therapy

Answer & Comments

Answer: 2- She may require a renal transplant in 10 years

The findings point to focal segmental glomerulosclerosis (FSGS), which leads to chronic renal failure in half of cases. The lack of resolution with corticosteroid therapy and the progression to chronic renal failure is what sets FSGS apart from minimal change disease.

[Q: 1175] OnExamination - Nephrology

A 55-year-old man who has received haemodialysis for many years presents with deteriorating discomfort in both shoulders. Past medical history included bilateral carpal tunnel decompression. His Investigations reveal:

haemoglobin 10 g/dl

ESR 30 mm/1st hr (1-10)

C-reactive protein 12mg/L (1-10)

Urate 0.58 mmol/L (less than 0.45)

What is the most likely diagnosis?

- 1- b2 microglobulin amyloidosis
- 2- gout
- 3- Pseudogout
- 4- Polymyalgia rheumatica
- 5- Osteoarthritis

Answer & Comments

Answer: 1- b2 microglobulin amyloidosis

The features of shoulder pain associated with a past history of carpal tunnel syndrome in a patient receiving haemodialysis suggests a diagnosis of b2 microglobulin amyloidosis. Amyloid deposits composed of b2-microglobulin as the major constituent protein are mainly localized in joints and periarticular bone and lead to destructive arthropathy which tends to develop 5 to 10 years after the initiation of dialysis. Death from amyloidosis

of gut and heart may occur after 20 years of dialysis.

[Q: 1176] OnExamination - Nephrology

A 16-year-old girl presented with Henoch-Schölein purpura and renal involvement.

What is the most likely outcome?

- 1- A high probability of relapse
- 2- Complete renal recovery
- 3- Persistent hypertension
- 4- Persistent proteinuria
- 5- Requirement for long-term corticosteroids

Answer & Comments

Answer: 2- Complete renal recovery

Henoch-Schölein Purpura (HSP) is a self-limiting vasculitis which occurs in children and young adults. It is characterized by non-thrombocytopenic purpura, arthralgia, abdominal pain and glomerular nephritis. It is likely to be an immune complex disease - involving IgA, but no treatment has proven efficacy. The disease usually settles between 4-6 weeks without sequelae if kidney involvement is mild. However this condition can occasionally relapse.

[Q: 1177] OnExamination - Nephrology

A 36-year-old male is referred with chronic renal dysfunction and is discovered to have Adult Polycystic Kidney Disease.

Which of the following proteins is associated with the development of APKD?

- 1- Cyst specific binding protein
- 2- Matrix metalloproteinase
- 3- Polycystin-1
- 4- Progesterone binding cyst-protein
- 5- Type 1 collagen

Answer & Comments

Answer: 3- Polycystin-1

Autosomal dominant PKD-1 is a relatively common disorder accounting for approx 8% of cases of ESRD. 85% of cases are due to the defect in PKD-1 locus on Chromosome 16p13.3. PKD-1 encodes a large protein, polycystin, which seems to be involved in cell to cell matrix interaction.

[Q: 1178] OnExamination - Nephrology

Autosomal recessive conditions include:

- 1- Vitamin D resistant rickets
- 2- Huntingdon's chorea
- 3- Wilson's disease
- 4- Manic depression
- 5- Turner's syndrome

Answer & Comments

Answer: 3- Wilson's disease

Vitamin D resistant rickets = X-linked dominant. No linkage has been established for a particular gene in manic depressive disorder.

[Q: 1179] OnExamination - Nephrology

A 17-year-old boy presented with a non-blanching rash over his legs, a swollen knee and painless frank haematuria. Investigations revealed:

Serum creatinine: 210 µmol/L (60-110)

Urine dipstick analysis: blood +++, protein +

Urine culture: negative

Ultrasound of the kidneys: normal

Which glomerular abnormality is most likely to be present at renal biopsy?

- 1- Focal and segmental sclerosis
- 2- Foot process fusion

- 3- Linear deposition of IgG on the basement membrane
- 4- Mesangial deposition of IgA
- 5- Thickening of basement membranes

Answer & Comments

Answer: 4- Mesangial deposition of IgA

The likely diagnosis here is Henoch-Schönlein Purpura (HSP). HSP is an inflammatory disorder of unknown cause characterized by IgA-dominant immune complexes in smaller venules, capillaries and arterioles. It presents with purpura, arthritis (especially ankles and knees), abdominal pains, haematuria and proteinuria.

HSP is often associated with infectious agents such as group A Streptococci and Mycoplasma. If there is progression to renal impairment then renal histopathology may include minimal change to severe glomerulonephritis that is indistinguishable from IgA nephropathy. However, mesangial Ig A deposits are the most typical features of HSP on renal biopsy.

[Q: 1180] OnExamination - Nephrology

A 65-year-old female is referred with a long history of hypertension and episodic urinary tract infections. Dipstick analysis of the urine shows Blood +++ together with protein +++. Her Urea is 20 mmol/l (3-8) and Creatinine 280 micromol/l (60-100). An ultrasound of abdomen is requested and shows left and right kidneys of 9 cm in size (10-12) without evidence of obstruction.

Which one of the following is the best investigation to diagnose the cause of her renal failure?

- 1- isotope renography
- 2- IV urography
- 3- renal angiography

- 4- renal biopsy
5- retrograde pyelography

Answer & Comments

Answer: 4- renal biopsy

This patient has impaired renal function, with hypertension and significant proteinuria and haematuria (? glomerulonephritis). The kidneys are smaller than expected, with no evidence of obstruction. Intravenous urography (B) is not the investigation of choice in a patient with impaired renal function. Isotope renography (A) would provide information about the relative function of each kidney, and would show areas of scarring due to renal stone disease, infection, or vascular disease. It would also exclude congenital malformations of the kidneys. Although useful, it would not provide information on the cause of the haematuria and proteinuria. Renal angiography (C) is the gold standard for assessing renovascular disease. It is an invasive procedure, with potential complications. This investigation would not exclude causes of proteinuria and haematuria. Retrograde pyelography (E) would be useful if there were any evidence of obstruction. The best investigation is a renal biopsy. This would show any changes of glomerulonephritis, along with renal scarring from longstanding hypertension or urinary tract infections.

[Q: 1181] OnExamination - Nephrology

A 72-year-old male presented to his GP with depression after the death of his wife. His notes also reveal that he has a two-year history of urinary hesitancy and poor stream. His GP prescribed him some medication and the following day he developed acute urinary retention.

Which of the following drugs is most likely to have precipitated the urinary retention?

- 1- Amitriptyline
2- Diazepam
3- Fluoxetine
4- Venlafaxine
5- Zopiclone

Answer & Comments

Answer: 1- Amitriptyline

Amitriptyline has anticholinergic effects being associated with tachycardia, dry mouth and urinary retention. These features are not typical of SSRIs such as Venlafaxine and Fluoxetine with urinary retention and dry mouth rarely reported. Diazepam, a benzodiazepine does not have anticholinergic effects. Zopiclone is a benzodiazepine like agent whose side effects include drowsiness.

[Q: 1182] OnExamination - Nephrology

A 25-year-old man developed bilateral loin pain and frank hematuria. His symptoms had started 24 hours after developing a sore throat. His blood pressure was 138/88 mmHg. Urinalysis was positive for blood (4+) and protein (2+).

What is the most likely diagnosis?

- 1- IgA nephropathy
2- microscopic polyangiitis
3- nephrolithiasis
4- post-streptococcal glomerulonephritis
5- septicaemia

Answer & Comments

Answer: 1- IgA nephropathy

The acute onset of the disease is suggestive of IgA nephropathy which characteristically occurs in young males in their 20s and 30s. Haematuria occurs within 12-24 hours of pharyngitis, accompanied also by loin pain,

muscle pain and fever. Prognosis is usually good especially in children. In adults, between 25-50% may develop end-stage renal failure. No specific treatment available. Classically, patient has streptococcal infection 1-3 weeks before the onset of acute nephritic syndrome (post-strep GN). There is a long prodromal systemic illness lasting months or years in microscopic polyangiitis which differs from Wegener's granulomatosis in its absence of respiratory tract granulomatous inflammation.

[Q: 1183] OnExamination -
Nephrology

A 19-year-old female developed pleural effusions, ascites and ankle swelling. Her blood pressure was 112/76 mmHg.

Investigations revealed:

serum alanine transferase 17 U/L (5 - 15)

serum total bilirubin 17 umol/L (1 - 22)

serum albumin 21 g/L (34 - 94)

serum total cholesterol 9.8 mmol/L (<5.2)

What is the next most appropriate investigation?

- 1- Antinuclear antibody
- 2- Pregnancy test
- 3- Prothrombin time
- 4- Serum protein electrophoresis
- 5- Urinary protein estimation

Answer & Comments

Answer: 5- Urinary protein estimation

The low albumin and elevated cholesterol would suggest nephrotic syndrome (>4gram protein/24hour urine). Other complications of nephritic syndrome include susceptibility to infection, thromboses, renal failure and protein malnutrition. The normal BP makes preeclampsia unlikely. Besides, the hypercholesterolaemia is the big clue.

[Q: 1184] OnExamination -
Nephrology

A 63-year-old woman presents following a visit to the well woman clinic where she is noted to be hypertensive. She has a past history of hip osteoarthritis for which she has taken regular paracetamol. On examination she is obese with a BMI of 35 (< 25), has a blood pressure of 180/100 mmHg and glycosuria is noted.

Her Investigations show:

Fasting plasma glucose 18.3 mmol/L

Serum urea 9.8 mmol/l

serum creatinine 129 micromol/L

24 hour urine protein concentration 1.8 g/d

Normal ultrasonic appearances of both kidneys

Which of the following is the most likely diagnosis?

- 1- Analgesic nephropathy
- 2- Chronic glomerulonephritis
- 3- Diabetic nephropathy
- 4- Hypertensive nephropathy
- 5- Ischaemic nephropathy

Answer & Comments

Answer: 3- Diabetic nephropathy

This patient is diabetic and has proteinuria. Although diabetic nephropathy usually takes 5 or more years to evolve, this patient is likely to have had the condition for many years prior to it now being diagnosed. Ischaemic nephropathy, due to renal artery stenosis is unlikely in the presence of a normal renal ultrasound. Analgesic nephropathy would be a consequence of NSAIDs not paracetamol. Hypertensive nephropathy is a possibility but is less likely in the context of her proteinuria and moderately elevated BP.

[Q: 1185] OnExamination -
Nephrology

A 68-year-old male diagnosed with nephrotic syndrome receives steroid therapy without benefit. His investigations show an albumin of 20 g/L (37 - 49), Total cholesterol of 12 mmol/L, dipstick urinalysis reveals +++ protein and a renal biopsy shows focal segmental glomerulosclerosis.

Which one of the following is most likely to preserve renal function?

- 1- dietary salt restriction
- 2- low dietary protein intake
- 3- ramipril
- 4- simvastatin
- 5- warfarin

Answer & Comments

Answer: 3- ramipril

Approximately 50% of subjects with FSGS do not respond to steroid therapy but ACE inhibitors are a recognized strategy to slow the progression of renal disease. This patient is clearly at high risk of cardiovascular disease with a very high cholesterol but the question specifically asks about renal disease.

[Q: 1186] OnExamination -
Nephrology

What is the most likely outcome of minimal change nephropathy with onset at 12 year of age?

- 1- frequent relapse
- 2- full renal recovery
- 3- permanent renal impairment
- 4- persistent hypertension
- 5- persistent proteinuria

Answer & Comments

Answer: 2- full renal recovery

30-40% of children achieve spontaneous remission and 90% achieve remission following 8 weeks treatment with high dose steroids. However in adults only around 50% achieve remission.

[Q: 1187] OnExamination -
Nephrology

In which of the following situations would a percutaneous needle biopsy of the kidney be most helpful and appropriate?

- 1- Fever with suspected acute pyelonephritis
- 2- Premature neonate with suspected polycystic kidney disease
- 3- Prostatic hyperplasia with suspected hydronephrosis
- 4- Suspected renal cyst
- 5- Systemic lupus erythematosus and acute renal failure

Answer & Comments

Answer: 5- Systemic lupus erythematosus and acute renal failure

Therapy may depend upon determination of the severity and nature of the renal disease with SLE. The presence of young age (<23 years) increased serum creatinine level, diffuse proliferative lesions (WHO classification class IV) and a high chronicity index on renal histologic analysis are associated with a poorer prognosis and risk of renal failure.

" Class I - Shows little or no changes. No treatment is necessary.

" Class II - Some mesangial lesions. If it is IIa, no treatment is necessary, but the patient needs to be monitored (by urine and blood tests). If IIb exists, especially in the presence of high anti-ds DNA, low complement, and over a gram of protein in the urine, then therapy needs to be initiated (usually prednisone).

" Class III & Class IV - These stages progress to endstage renal failure in about 50% of the cases, so aggressive therapy is warranted. Treatment ranges from prednisone to IV cytotoxic drugs.

" Class V - Membranous lesions are usually treated with prednisone. Cytotoxic drugs are not *usually* effective, unless there is concurrent evidence of classes III or IV.

[Q: 1188] OnExamination - Nephrology

Acute renal failure may be distinguished from chronic renal failure by which of the following?

- 1- an increased urinary Na excretion
- 2- left ventricular hypertrophy on the ECG
- 3- hypophosphataemia
- 4- renal size on ultrasound scan
- 5- hyperkalaemia

Answer & Comments

Answer: 4- renal size on ultrasound scan

Small kidneys on USS suggest chronic renal failure but the following causes of chronic renal failure can present with normal / enlarged kidneys - amyloidosis, polycystic kidney disease, diabetic glomerulosclerosis, scleroderma and rapidly progressive glomerulonephritis.

Decreased fractional Na clearance, hyperphosphataemia and hyperkalaemia are features of acute or chronic renal failure.

LVH is probably more likely to be seen in chronic renal failure but is not reliable.

[Q: 1189] OnExamination - Nephrology

A 55-year-old man who has received haemodialysis for many years presents with deteriorating discomfort in both shoulders. Past medical history included bilateral carpal

tunnel decompression. His Investigations reveal:

haemoglobin 10 g/dl

ESR 30 mm/1st hr (1-10)

C-reactive protein 12mg/L (1-10)

Urate 0.58 mmol/L (less than 0.45)

What is the most likely diagnosis?

- 1- b2 microglobulin amyloidosis
- 2- Gout
- 3- Pseudogout
- 4- Polymyalgia rheumatica
- 5- Osteoarthritis

Answer & Comments

Answer: 1- b2 microglobulin amyloidosis

The features of shoulder pain associated with a past history of carpal tunnel syndrome in a patient receiving haemodialysis suggests a diagnosis of b2 microglobulin amyloidosis. Amyloid deposits composed of b2-microglobulin as the major constituent protein are mainly localized in joints and periarticular bone and lead to destructive arthropathy which tends to develop 5 to 10 years after the initiation of dialysis. Death from amyloidosis of gut and heart may occur after 20 years of dialysis.

[Q: 1190] OnExamination - Nephrology

A 54-year-old man with intermittent claudication was found to have renal impairment. Investigations revealed:

Serum creatinine: 180 umol/L (60-100)

Urinalysis: Protein++

Renal ultrasound revealed a right kidney of 7 cms and a left kidney of 10cms (normal dimensions 10-14cm)

Which investigation should be requested to establish the diagnosis?

- 1- Cystoscopy
- 2- Intravenous urography
- 3- Isotope renography
- 4- Renal arteriography
- 5- Renal biopsy

Answer & Comments

Answer: 4- Renal arteriography

This patient has renovascular disease with a left renal artery stenosis. The gold standard for establishing the diagnosis of renal artery stenosis is renal arteriography and this is commonly performed with magnetic resonance angiography. In 1/3 of cases the disease is bilateral; 40% may have peripheral vascular disease and there may be proteinuria.

[Q: 1191] OnExamination - Nephrology

An 81-year-old man was admitted with renal failure due to benign prostatic hypertrophy. His bladder was drained with a urethral catheter followed by a diuresis of > 3L per day. After two days he became progressively drowsy.

What is the most likely cause for his reduced level of consciousness?

- 1- hyponatraemia
- 2- hypocalcaemia
- 3- hypomagnesaemia
- 4- hyperglycaemia
- 5- metabolic acidosis

Answer & Comments

Answer: 1- hyponatraemia

Amelioration of urinary obstruction and subsequent recovery initially results in a large electrolyte and water loss. Osmotic cerebral changes precipitated by urinary sodium loss,

the major intravascular cation, is the cause of drowsiness. Hypocalcaemia and hypomagnesaemia may occur as tubular reabsorption is suboptimal in the early stages of recovery, but is unlikely to affect conscious level. Acid-base status should improve after relief of the obstruction. Hyperglycaemia is not a common complication of recovery from obstructive uropathy.

[Q: 1192] OnExamination - Nephrology

A 45-year-old male presents with a long-standing history of hypertension. Investigations show a urea of 10.2 mmol/l and a Creatinine of 150 micromol/l (50-100).

Which one of the following would suggest a diagnosis of acute glomerulonephritis?

- 1- 24 hour urinary protein excretion of 0.8g
- 2- Dyslipidaemia
- 3- RBC casts in urinary sediment
- 4- Shrunken glomeruli on renal biopsy
- 5- Unilaterally smaller kidney

Answer & Comments

Answer: 3- RBC casts in urinary sediment

Casts containing erythrocytes (red cell casts) are an indication of renal bleeding, and are typically found when there is acute glomerular inflammation caused by glomerulonephritis or vasculitis. Answers A, B, D, and E are non specific and do not suggest an acute glomerulonephritis.

[Q: 1193] OnExamination - Nephrology

A 46-year-old woman develops nephrotic syndrome and is awaiting further tests to establish the underlying aetiology.

In which circumstance would corticosteroids be most effective in reversing the nephrotic syndrome?

- 1- Membranous nephropathy
- 2- Minimal change disease
- 3- Primary amyloidosis
- 4- Renal vein thrombosis
- 5- Mesangial IgA disease

Answer & Comments

Answer: 2- Minimal change disease

Although there is no known effective treatment for IgA nephropathy, there have been reports of favourable response to long term corticosteroid therapy. 80% adults with minimal change GN will respond to steroids, although remissions can take up to 16 weeks. Membranous GN does not respond to steroid treatment. No specific treatment is available to cause regression of amyloid deposits.

[Q: 1194] OnExamination -
Nephrology

A 33-year-old male is receiving regular haemodialysis is noted to have a plasma potassium of 6.9 mmol/L (3.5-4.9) before a dialysis session. Although normally his potassium is less than 5.5 mmol/L.

Which food combination from the dietary history would be most likely to cause the high potassium concentration?

- 1- Cereal, toast, biscuits.
- 2- Filter coffee, tea, boiled potatoes.
- 3- Milk, butter, plain yoghurt
- 4- Milk, ham, chicken.
- 5- Tomato, potato crisps, banana.

Answer & Comments

Answer: 5- Tomato, potato crisps, banana.

In particular tomato and banana have high potassium content and patients should be advised to avoid such foods.

[Q: 1195] OnExamination - Clinical pharmacology

A 67-year-old man who has a long history of chronic bronchitis is admitted from home with an acute exacerbation.

Investigations show:

pCO₂ 82 mmHg (35-45)

pO₂ 50 mmHg (90 - 110)

Which of the following would be expected in this patient?

- 1- A metabolic acidosis with a low bicarbonate would be expected
- 2- Extensor plantar responses may be expected
- 3- Gentamicin would be a reasonable initial treatment until cultures are available
- 4- Oxygen therapy should aim to increase the pO₂ to above 60mmHg (8kPa)
- 5- Peripheral oedema indicates coexisting heart failure

Answer & Comments

Answer: 2- Extensor plantar responses may be expected

In chronic bronchitis, a low pO₂ with high pCO₂ and compensated respiratory acidosis with high bicarbonate is expected. Consequently with the high pCO₂ an encephalopathy may be precipitated resulting in extensor plantar responses. The figures given suggest a respiratory acidosis.

BTS guidelines would recommend treatment of exacerbations with amoxicillin or cephalosporin

Oxygen therapy should be given cautiously aiming to maintain a pCO₂ between 50-60mmHg (see Harrisons - Principles of Internal Medicine), this is debateable but the point is that the aim should not be a normal pO₂ but rather a sufficient pO₂ particularly in 'blue bloaters' (type II respiratory failure). Extensor

plantar responses are a feature often reflecting high pCO₂

There may be a dependent (postural) oedema and does not necessarily indicate heart failure.

[Q: 1196] OnExamination - Clinical pharmacology

A 65-year-old man presented with chest pain and was found to have ST elevation in leads II, III and aVF. He was thrombolysed and has been stable on coronary care.

On the third day of admission he becomes confused and on reviewing the history it becomes apparent that he was a heavy alcohol drinker before admission taking 80 units of alcohol per week.

Which of the following management options would be most helpful in this situation?

- 1- CT brain scan
- 2- Diazepam
- 3- Haloperidol
- 4- Psychiatric referral
- 5- Thiamine

Answer & Comments

Answer: 2- Diazepam

This man is withdrawing from alcohol and this is associated with anxiety and tachycardia which is the last thing that someone who has just had an MI should suffer from. Also there is a risk of seizure. Benzodiazepines are the first line of treatment for withdrawal. Thiamine is also indicated in chronic alcoholism but is not as immediately important as diazepam. A psychiatric referral may be necessary if his symptoms prove difficult to control but usually the psychiatry team would not be keen to intervene in what is really a medical emergency; they often advise on other strategies for sedation however. This is unlikely to be an intracerebral bleed from thrombolysis on the third day but

a CT scan may be indicated if there are focal neurological signs. Haloperidol is best avoided because of the risk of causing hypotension.

[Q: 1197] OnExamination - Clinical pharmacology

A 17-year-old boy is admitted with a severe paracetamol overdose following an argument with his girlfriend. He is treated with intravenous N-acetylcysteine. Paracetamol is normally metabolised to harmless compounds except in overdose.

Which of the following compounds is the toxic metabolite that accumulates during paracetamol overdose and is reduced by treatment with N-acetylcysteine?

- 1- Glucuronide
- 2- Homocysteine
- 3- Methionine
- 4- N-acetyl-p-benzoquinoneimine
- 5- N-hydroxyacetaminophen

Answer & Comments

Answer: 4- N-acetyl-p-benzoquinoneimine

Paracetamol is predominantly metabolised to glucuronide and sulphate conjugates, which are excreted in the urine. Hepatotoxicity is related to the conversion of a small proportion of the ingested dose to N-acetyl-p-benzoquinoneimine. In therapeutic doses N-acetyl-p-benzoquinoneimine is detoxified by conjugation with glutathione in the liver, but once the protective intracellular glutathione stores are depleted hepatic and renal damage may ensue. NAC and Methionine replenishes glutathione stores in the liver and may also act through its Sulphydryl (-SH) group as a direct reducing agent.

[Q: 1198] OnExamination - Clinical pharmacology

In a trial of a new drug, 13/28 treated

improved over a one month period, compared with 3/28 on placebo.

For Chi² testing which of the following is correct?

- 1- The figures should first be converted to percentages.
- 2- The results would almost certainly suggest that more cases were needed to obtain a significant result.
- 3- There is one degree of freedom.
- 4- A value of Chi² of 4.6 would imply that the result would have been obtained by chance in 46/100 trials.
- 5- The results would be invalidated if a disproportionate number of cases treated with the new drug had developed side effects.

Answer & Comments

Answer: 3- There is one degree of freedom.

Chi² testing refers to count data (categorical). It therefore refers to 2 by 2 tables or larger. The test statistic is defined by:

$$\text{Chi}^2 = \frac{\sum (\text{observed} - \text{expected})^2}{\text{expected}}$$

The degrees of freedom equal (rows -1) x (Columns -1). Significance can be looked up using the Chi² distribution according to the appropriate number of degrees of freedom.

[Q: 1199] OnExamination - Clinical pharmacology

A 71-year-old male with a history of chronic renal impairment and atrial fibrillation for which he takes warfarin, presents with an acutely tender and red left big toe.

Investigations reveal:

Serum Creatinine 200 micromol/l (50-100)

Serum Urate 0.5 mmol/l (0.12-0.42)

Which of the following is the most appropriate treatment for this man's presentation?

- 1- Allopurinol
- 2- Colchicine
- 3- Diclofenac
- 4- Paracetamol
- 5- Prednisolone

Answer & Comments

Answer: 5- Prednisolone

This man presents with acute gout, has chronic renal impairment, AF and takes warfarin. NSAIDs would be the treatment of choice but may cause both a deterioration in renal function and INR. Similar reasons would obviate the use of Colchicine. Thus, Steroids are probably the best option. Allopurinol may well precipitate/exacerbate acute gout and are used once the acute attack has settled following adequate treatment.

[Q: 1200] OnExamination - Clinical pharmacology

A 40-year-old lady presents with a swollen right calf. She has a history of mental health problems and is on a number of medications.

Which of the following treatments increases the risk of thromboembolism?

- 1- Antipsychotics
- 2- Benzodiazepines
- 3- Monoamine oxidase inhibitors
- 4- Selective serotonin reuptake inhibitors
- 5- Tricyclic antidepressants

Answer & Comments

Answer: 1- Antipsychotics

The oral contraceptive and antipsychotics are possible causes of thromboembolism.

[Q: 1201] OnExamination - Clinical pharmacology

A 50-year-old lady is brought into the

Emergency department with drowsiness following an overdose of amitriptyline. She has dilated pupils, a GCS of 12, pulse 140 bpm, BP 85/60 and her ECG shows a wide complex tachycardia.

Which of the following is the most appropriate next step in management?

- 1- Carotid sinus massage
- 2- DC cardioversion
- 3- IV bicarbonate
- 4- IV magnesium
- 5- Refer for haemodialysis

Answer & Comments

Answer: 3- IV bicarbonate

This lady has a significant tricyclic overdose and the ventricular dysrhythmias can be very difficult to control. Management with IV bicarbonate is indicated.

"The use of sodium bicarbonate in tricyclic poisoning has been shown to have beneficial effects. ... In a review of 91 patients treated with sodium bicarbonate, hypotension was corrected in 20 of 21 patients (96%) within one hour and QRS prolongation was corrected in 39 of 49 patients (80%). ... The mechanism of this effect is a subject of debate."

[Q: 1202] OnExamination - Clinical pharmacology

A 70-year-old woman is on multiple medications for various conditions and she is found to have a macrocytic anaemia with a low serum B12.

Which of the following medications is a possible cause of the B12 deficiency?

- 1- Amiodarone
- 2- Ezetimibe
- 3- Metformin
- 4- Nicotinic acid

5- Sodium valproate

Answer & Comments

Answer: 3- Metformin

Metformin can lead to reduced B12 absorption but this is not usually a clinical problem.

"The clinician must be aware of the possibility of metformin-associated B12 deficiency in users who suffer cognitive impairment, peripheral neuropathy, subacute combined degeneration of the cord or anaemia."

[Q: 1203] OnExamination - Clinical pharmacology

A 35-year-old man with a known history of acute intermittent porphyria because he carries a medical emergency card is brought to the emergency department by the police; he has been violent with acute psychosis.

Which of the following sedatives would be the safest to use in this circumstance?

- 1- Chloral hydrate
- 2- Chlorpromazine
- 3- Diazepam
- 4- Haloperidol
- 5- Phenobarbitone

Answer & Comments

Answer: 2- Chlorpromazine

Phenothiazines have antiemetic and antipsychotic properties, making them the medication of choice for acute porphyria episodes.

[Q: 1204] OnExamination - Clinical pharmacology

Phenytoin:

- 1- Is associated with red-green colour blindness

- 2- Toxicity is associated with orchitis

- 3- A steady state blood level is achieved by 2-5 days

- 4- Can be used in management of alcohol withdrawal syndrome

- 5- Is the drug of choice in absence seizures.

Answer & Comments

Answer: 4- Can be used in management of alcohol withdrawal syndrome

Phenytoin is an imidazolidine derivative. It relates to barbiturates in chemical structure. Clinically effective serum level is in the range on 10-20 micrograms/ml. A steady state blood level is achieved by 7-10 days.

[Q: 1205] OnExamination - Clinical pharmacology

A 52-year-old woman takes Lithium Carbonate for manic depression and also takes Codeine and Diclofenac prescribed by her GP for osteoarthritis.

Which one of the following statements is correct?

- 1- Codeine will reduce the bioavailability of Lithium
- 2- The analgesic effect of Codeine will be reduced by co-administration of Diclofenac
- 3- The nephrotoxicity of Diclofenac will be increased in this patient
- 4- Plasma Lithium concentration will be increased by Codeine
- 5- Plasma Lithium concentrations will be raised by Diclofenac

Answer & Comments

Answer: 5- Plasma Lithium concentrations will be raised by Diclofenac

Diclofenac decreases renal Lithium clearance and increases Lithium concentrations. Codeine and diclofenac are frequently co-prescribed.

[Q: 1206] OnExamination - Clinical pharmacology

A patient is suspected of having taken a substance with anticholinesterase effects.

Which of the following combinations of signs, if present, would be the most likely to confirm this effect?

- 1- Bradycardia and miosis
- 2- Bradycardia and mydriasis
- 3- Bradycardia and urinary retention
- 4- Tachycardia and diarrhoea
- 5- Tachycardia and lacrimation

Answer & Comments

Answer: 1- Bradycardia and miosis

An Acetylcholinesterase inhibitor or Anti-cholinesterase is a chemical that inhibits the cholinesterase enzyme from breaking down acetylcholine (ACh), so increasing both the level and duration of action of the neurotransmitter acetylcholine. ACh can stimulate postganglionic receptors to produce effects such as salivation, lacrimation, defecation, micturition, sweating, miosis, bradycardia, and bronchospasm. Muscarine produces these effects, and hence they are referred to as muscarinic effects, and the postganglionic receptors are called muscarine receptors.

SLUD (Salivation, Lacrimation, Urination, Defecation [and emesis]) is a syndrome of pathological effects indicative of massive discharge of the parasympathetic nervous system. Unlikely to occur naturally, SLUD is usually encountered only in cases of drug overdose or exposure to nerve gases. Nerve gases irreversibly inhibit the enzyme acetylcholinesterase; this results in a chronically high level of acetylcholine at cholinergic synapses throughout the body, thus chronically stimulating acetylcholine receptors throughout the body.

[Q: 1207] OnExamination - Clinical pharmacology

Which of the following mechanisms best explains the action of fibrates?

- 1- Activation of PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 1- Activation of PPAR-alpha

The effect of fibrates on the metabolism of triglyceride-rich lipoproteins is due to a PPAR-alpha-dependent stimulation of lipoprotein lipase and of apolipoprotein (apo)A-V and to an inhibition of apoC-III expression, whereas the increase in plasma HDL-cholesterol depends partly on an overexpression of apoA-I and apoA-II.

[Q: 1208] OnExamination - Clinical pharmacology

Which term best describes the affinity of a drug for its receptor?

- 1- Efficacy
- 2- Intrinsic activity
- 3- Potency
- 4- Selectivity
- 5- Therapeutic effect

Answer & Comments

Answer: 3- Potency

Affinity is the measure of the net molecular attraction between a drug (or neurotransmitter or hormone) and its receptor. The receptor's affinity for binding a drug determines the concentration of drug required to form a significant number of drug-

receptor complexes. Affinity and intrinsic activity are determinants of potency. Efficacy contributes both to potency and to the maximum effect of the agonist. Efficacy is a measure of the efficiency of the drug-receptor complex in initiating the signal transduction process.

[Q: 1209] OnExamination - Clinical pharmacology

Which of the following statements regarding Antabuse (Disulfiram) are correct?

- 1- Can be used to assist abstinence from alcohol in patients with heart disease.
- 2- Antabuse acts by promoting the metabolism of acetaldehyde
- 3- Patients using alcohol based perfumes may develop serious reactions
- 4- Requires regular dose titration once initiated
- 5- Can be used in patients with a history of psychosis in order to limit alcohol excess

Answer & Comments

Answer: 3- Patients using alcohol based perfumes may develop serious reactions

Antabuse inhibits the breakdown of acetaldehyde, which is a major metabolite of alcohol. It is the accumulation of acetaldehyde which causes the flushing, sweating, palpitations, nausea and vomiting seen in patients taking Antabuse who imbibe alcohol. These reactions may also occur with alcohol based products e.g. perfume. Antabuse is contraindicated in cirrhosis and heart disease, and psychosis is a relative contraindication for its use.

[Q: 1210] OnExamination - Clinical pharmacology

A 72-year-old female is diagnosed with giant cell arteritis and is treated with Prednisolone 60 mg per day.

What is the most appropriate treatment for the prevention of steroid induced osteoporosis?

- 1- Alfacalcidol
- 2- Calcium
- 3- Raloxifene
- 4- Tibolone
- 5- Vitamin D

Answer & Comments

Answer: 1- Alfacalcidol

The National Osteoporosis Society/ RCP Guidelines were updated in 2002. Patients older than 65 years are considered at high risk of osteoporotic fractures secondary steroid induced osteoporosis. The algorithm for treatment can be found on the National Osteoporosis Society website. Daily intake 1,500mg of calcium and 800U of Vit D3 is recommended. Bone mass measurements at baseline and follow up measurements will guide future therapeutic decisions in patients on long term steroids. There is also evidence to support the use of Bisphosphonates and calcitonin in these patients.

[Q: 1211] OnExamination - Clinical pharmacology

A 62 year-old female presents with deteriorating arthralgia associated with long-standing Rheumatoid arthritis. She was prescribed Celecoxib in place of naproxen.

Which of the following concerning Celecoxib is correct?

- 1- Co-treatment with diuretic can be given more safely than with naproxen
- 2- Celecoxib acts by inhibiting a different enzyme than naproxen
- 3- Celecoxib has a lower level of anti-platelet activity than naproxen
- 4- Anti-inflammatory effects of celecoxib are superior to those of naproxen

- 5- Celecoxib is associated with reduced hepatotoxicity compared with naproxen

Answer & Comments

Answer: 3- Celecoxib has a lower level of anti-platelet activity than naproxen

Celecoxib is a COX (Cyclo-oxygenase)-2 inhibitor differing from the other NSAIDs such as Naproxen which affects both COX-1 and COX-2. COX-1 is involved in platelet aggregation and inhibition of this by the NSAIDs produces its beneficial cardiovascular effects. However platelet aggregation is not affected by COX-2. Rofecoxib, Vioxx has been withdrawn due to its increased cardiovascular events compared with Naproxen.

[Q: 1212] OnExamination - Clinical pharmacology

Which of the following cardiac drugs shorten the QT interval?

- 1- Amiodarone
- 2- Digoxin
- 3- Moxonidine
- 4- Sodium nitroprusside
- 5- Sotalol

Answer & Comments

Answer: 2- Digoxin

Hypercalcemia, hypermagnesemia, digoxin, or thyrotoxicosis cause QT shortening.

[Q: 1213] OnExamination - Clinical pharmacology

The nurse bleeped you because an obese patient is feeling nauseous and is vomiting. He is also complaining of seeing green and yellow halos. He has recently been treated with a standard intravenous bolus of digoxin for fast atrial fibrillation. His creatinine clearance is normal. Digoxin toxicity is suspected.

What do you think is the cause of his symptoms?

- 1- Decreased hepatic excretion
- 2- Decreased protein binding
- 3- Decreased renal clearance
- 4- Decreased volume of distribution
- 5- Increased half life

Answer & Comments

Answer: 4- Decreased volume of distribution

Digoxin is concentrated in tissues and therefore has a large apparent volume of distribution. Serum digoxin concentrations are not significantly altered by large changes in fat tissue weight, so that its distribution space correlates best with lean (i.e., ideal) body weight, not total body weight. In this case, a higher dose than necessary was given due to calculation on the patient total body weight, resulting in digoxin toxicity. In other words, his distribution space had been overestimated. Approximately 25% of digoxin in the plasma is bound to protein.

[Q: 1214] OnExamination - Clinical pharmacology

Which of the following antiemetics functions through inhibition of neurokinin (NK) 1 receptor?

- 1- Aprepitant
- 2- Domperidone
- 3- Hyoscine
- 4- Granisteron
- 5- Ondansetron

Answer & Comments

Answer: 1- Aprepitant

Aprepitant is a neurokinin receptor blocker used in the prevention of chemotherapy induced nausea. Ondansetron and granisetron

are 5HT₃ antagonists. Hyoscine is an anticholinergic/antihistaminergic. Domperidone is an antidopaminergic agent.

[Q: 1215] OnExamination - Clinical pharmacology

With respect to symptoms of withdrawal related to chronic alcohol use, which of the following statements is correct?

- 1- Withdrawal reflects enhanced neurotransmission in Type A gamma-aminobutyric acid pathways.
- 2- Withdrawal reflects reduced neurotransmission in N-methyl-D-aspartate pathways.
- 3- Phenytoin is an effective treatment for seizures related to alcohol withdrawal.
- 4- Benzodiazepines are ineffective in the treatment of seizures secondary to alcohol withdrawal, due to cross tolerance with ethanol at Type A gamma amino-aminobutyric acid receptor.
- 5- Carbamazepine is as effective as Benzodiazepines in the acute treatment of the symptoms of alcohol withdrawal.

Answer & Comments

Answer: 5- Carbamazepine is as effective as Benzodiazepines in the acute treatment of the symptoms of alcohol withdrawal.

Carbamazepine at a starting dose of 800mg per 24hours has been shown to be as effective as oxazepam in the treatment of acute alcohol withdrawal. Phenytoin is not effective in the treatment of alcohol withdrawal-related seizures. Alcohol withdrawal reflects the damping of neurotransmission through Type A gamma-amino-butyric pathways, and enhanced neurotransmission through N-methyl-D-aspartate pathways.

For a review see NEJM348:18;1788-90.

[Q: 1216] OnExamination - Clinical pharmacology

A 60-year-old man presented with a rash over his forearms, shins and face when he visited cardiology clinic in the summer.

Which of the following medications is the most likely to be associated with this photosensitive rash?

- 1- Atenolol
- 2- Bendroflumethiazide
- 3- Clopidogrel
- 4- Digoxin
- 5- Ezetimibe

Answer & Comments

Answer: 2- Bendroflumethiazide

Photosensitivity is a common adverse effect and the cardiology drugs affected include amiodarone and thiazide diuretics. ACE inhibitors and ARAs commonly cause rashes some of which appear to be photosensitive.

[Q: 1217] OnExamination - Clinical pharmacology

A letter published in a medical journal suggests that an established antidepressant may cause photosensitivity. The manufacturer wishes to set up a study to determine rapidly and efficiently whether this is a true association.

Which one of the following techniques is most appropriate?

- 1- case control study
- 2- dose ranging study
- 3- double blind, randomized, placebo controlled study
- 4- meta-analysis
- 5- sequential trial

Answer & Comments

Answer: 4- meta-analysis

The drug is an established one and the correct answer can be found by elimination. A "double-blind, randomized, placebo controlled study" would be time consuming, expensive and unlikely to be powered enough to detect what may be a rare toxic effect. Remember the drug is established so there have been many patients taking it already and only lately a letter is published in a medical journal. A "dose ranging study" is really for another purpose - to decide the correct dose in early clinical trials so is hardly going to be of any use here. A "sequential" trial would be comparing one therapy to another sequentially (usually with wash out periods in between). Again there are unlikely to be enough subjects in the trial for this small risk. A case control study would look at cases of photosensitivity (perhaps in subjects taking any antidepressant medication) and compare them to age matched (or other criteria matched) control subjects to see if they were more / less / equally likely to be on the antidepressant in question.

A "meta-analysis" would look at combining all previous data and there would have at least been some of the trials that looked at photosensitivity for it to be of any use in this case. This seems the more logical option.

[Q: 1218] OnExamination - Clinical pharmacology

A 60-year-old lady is taking warfarin for stroke prevention in atrial fibrillation. She presents with a markedly raised INR.

Which of the following medications is the most likely to be the reason?

- 1- Aspirin
- 2- Carbamazepine
- 3- Ciprofloxacin
- 4- Flucloxacillin

5- St John's Wort

Answer & Comments

Answer: 3- Ciprofloxacin

Ciprofloxacin is an inhibitor of p450 and therefore prolongs the half life of warfarin and raises INR. Even patients are aware of the increased risk of bleeding with aspirin but it does not have a clear relationship with INR.

[Q: 1219] OnExamination - Clinical pharmacology

A 58-year-old female presented with unsteadiness and ataxia and gave a recent history of nausea and epigastric pain for which she had been prescribed an antacid and cimetidine. She was an epileptic and had been well controlled with phenytoin for eight years. She had been also been prescribed amitriptyline for depression, was receiving post-menopausal hormone replacement therapy and was self-medicating with St John's wort.

Which of the following drugs is most likely to be responsible for her presentation?

- 1- Amitriptyline
- 2- Antacid
- 3- Cimetidine
- 4- estradiol
- 5- St John's wort

Answer & Comments

Answer: 3- Cimetidine

This patient has developed phenytoin toxicity which has been precipitated by cimetidine which inhibits cytochrome P450 metabolism of phenytoin. Phenytoin concentration is reduced by St John's Wort, unaffected by amitriptyline which would however reduce seizure threshold; antacids may reduce phenytoin absorption and oestradiol metabolism may be increased by phenytoin.

[Q: 1220] OnExamination - Clinical pharmacology

Which of the following drugs is most likely to cause systemic lupus-like syndrome?

- 1- baclofen
- 2- isoniazid
- 3- methotrexate
- 4- procainamide
- 5- sulphasalazine

Answer & Comments

Answer: 4- procainamide

A recessive gene is responsible for activity of hepatic N-acetyl transferase resulting in slow or fast (intermediate and fast groups get lumped together) acetylation. 45% of the UK population are slow acetylators. Drugs affected include isoniazid, hydralazine, dapsone, procainamide and sulphasalazine. Slow acetylators have increased risk of isoniazid-induced peripheral neuropathy, and hydralazine or procainamide-induced SLE. Fast acetylators were considered more at risk of isoniazid-induced hepatitis but this is not borne by the recent evidence.

[Q: 1221] OnExamination - Clinical pharmacology

A 55 old male has been taking Methotrexate 7.5 mg weekly for sero-negative erosive rheumatoid arthritis with considerable clinical and symptomatic improvement. His most recent investigations performed two days ago reveals the following:

Haemoglobin 12.9 g/dl (12 - 16 g/dl)
 White cell Count $5.3 \times 10^9/L$ ($3.5 - 10 \times 10^9 /L$)
 Platelets $183 \times 10^9/L$ ($150 - 450 \times 10^9 /L$)
 Urea 4.2 mmol/l (3.8 - 8 mmol/L)
 Creatinine 88 $\mu\text{mol/l}$ (50 - 110 mmol/l)
 Alkaline phosphatase 92 iu/l (50 - 110 iu/l)
 AST 22 iu/l (5 - 40 iu/l)

ALT 15 iu/l (5 - 40 iu/l)

When should the next series of blood tests be performed?

- 1- One week
- 2- Two weeks
- 3- One month
- 4- Six months
- 5- One year

Answer & Comments

Answer: 3- One month

His results are normal and, with him receiving a stable dose of methotrexate, the most appropriate time interval for monitoring his profiles according to Prodigy, which should include FBC, Creatinine and AST/ALT, would be in one month. Similarly, the British Society of Rheumatology suggest monthly FBC when the results are stable.

[Q: 1222] OnExamination - Clinical pharmacology

A 60-year-old retired nurse with idiopathic Parkinson's disease presented with motor oscillations and on-off periods. She had received Co-Beneldopa for 5 years. Selegiline was added to her treatment.

Which one of the following enzymes does Selegiline act on to cause this adjuvant action?

- 1- catechol-O-methyltransferase
- 2- dopa decarboxylase
- 3- dopamine hydroxylase
- 4- monoamine oxidase
- 5- tyrosine hydroxylase

Answer & Comments

Answer: 4- monoamine oxidase

Selegiline is a MAO-B inhibitor.

[Q: 1223] OnExamination - Clinical pharmacology

A 30-year-old patient with learning difficulties is admitted as a medical emergency. The patient complains of headache, anorexia and vomiting. On examination she is febrile with a temperature of 38°C, pulse 110 bpm and is clinically jaundiced. Investigations reveal:

Bilirubin micromol/l (0-18)

Albumin 28 g/l (35-45)

AST 400 iu/l (5-40)

Alkaline Phosphatase 400 iu/l (50-120)

Prothrombin time 35 seconds (<14)

She was commenced on a new medication within the last 3 months, which do you suspect maybe contributing to the presentation?

- 1- Cabergoline
- 2- Carbamazepine
- 3- Lamotrigine
- 4- Metformin
- 5- Sodium Valproate

Answer & Comments

Answer: 5- Sodium Valproate

Sodium Valproate can occasionally have an idiosyncratic response leading to severe or even fatal hepatic toxicity. This is more common if the patient has a metabolic or degenerative disorder, organic brain disease or severe seizures associated with mental retardation. Usually this reaction occurs within the first 3 months of therapy.

Carbamazepine can be associated with jaundice occasionally however the history of mental retardation and short history of drug use point to sodium valproate as the cause. Lamotrigine can disrupt LFTs. Metformin and Cabergoline do not effect liver function however caution is advised when using these drugs in patients with hepatic disease.

[Q: 1224] OnExamination - Clinical pharmacology

A 45-year-old woman with a known history of depression, previously well controlled with fluoxetine, has started to suffer from anxiety, loss of interest and reduced appetite. She also complains of insomnia. She claims to taking her medications regularly according to prescription.

What will be the most appropriate management for her?

- 1- Add a benzodiazepine
- 2- Add lithium
- 3- Electroconvulsive therapy
- 4- Switch to another group of antidepressant
- 5- Switch to another SSRI

Answer & Comments

Answer: 4- Switch to another group of antidepressant

This patient has failed to respond to Fluoxetine. To switch to another group of antidepressant, especially a newer agent like Mirtazapine is a feasible approach. Mirtazapine is a newer antidepressant that exhibits both noradrenergic and serotonergic activity and was found to be an effective treatment for a substantial proportion of patients for whom an SSRI was ineffective and/or poorly tolerated.

[Q: 1225] OnExamination - Clinical pharmacology

A 45-year-old lady with a past history of depression presented to the Emergency department drowsy. He repeat prescription says she is taking diazepam and dosulepin and the ambulance crew say that she has taken an overdose of her medication. Her BP is 140/80, pulse 130 bpm, respiratory rate 7 per minute and O₂ sats 98% on air.

Which of the following is the most appropriate next action?

- 1- Give flumazenil
- 2- Give naloxone
- 3- Obtain an ECG
- 4- Refer for urgent haemodialysis
- 5- Start N-acetylcysteine infusion

Answer & Comments

Answer: 3- Obtain an ECG

This is a tricky case and will catch those who go for the first answer they see that's reasonable. The urge is to quickly treat the drowsy patient with respiratory depression with some sort of antidote but there needs to be a diagnostic step first. Tricyclic antidepressants can cause fatal arrhythmias and seizures which are very difficult to manage. An ECG would immediately indicate if there is a risk of significant tricyclic toxicity by showing a wide QRS complex or abnormal axis deviation.

[Q: 1226] OnExamination - Clinical pharmacology

A 55-year-old male who is being treated with Lithium for a bipolar disorder has a long history of hypertension for which he is receiving escalating doses of medication. On his most recent visit to clinic his blood pressure was noted to be 166/102 mmHg and new antihypertensive was added to his current antihypertensive therapy. Five days later he presents with features of Lithium toxicity including tremor, nausea and weakness.

The addition of which of the following drugs was likely to have precipitated the Lithium toxicity?

- 1- Doxazosin
- 2- Hydralazine
- 3- Irbesartan

- 4- Minoxidil
- 5- Moxonidine

Answer & Comments

Answer: 3- Irbesartan

The precipitation of Lithium toxicity by diuretics is well appreciated. Yet ACE inhibitors and Angiotensin Antagonists are also capable of precipitating Lithium toxicity through reduced Lithium clearance. Other drugs that may precipitate Lithium toxicity include NSAIDs, tetracycline, phenytoin and ciclosporin.

[Q: 1227] OnExamination - Clinical pharmacology

A 22-year-old male is admitted after drinking engine coolant in an apparent suicide attempt after finding his wife in bed with the postman. Investigations reveal:

pH 7.1
pO₂ 15.3 kPa
pCO₂ 3.2 kPa
Standard Bicarbonate 2.2 mmol/l
Serum Calcium 1.82 mmol/l

After replacing calcium, which of the following is the most appropriate treatment for this man?

- 1- Alcohol infusion
- 2- 8.4% bicarbonate infusion
- 3- Femopizole infusion
- 4- Gastric lavage
- 5- Haemodialysis

Answer & Comments

Answer: 2- 8.4% bicarbonate infusion

Engine coolant contains ethylene glycol. Ingestion of as little as 30-60ml is capable of causing death. Traditional management of poisoning includes the use of ethanol, with or

without hemodialysis. Activated charcoal is not indicated, and gastric lavage may be beneficial only in the first hour after ingestion. However, fomepizole, has recently been approved for use and is a competitive inhibitor of alcohol dehydrogenase. However, it is very expensive and the evidence supporting its use over alcohol is lacking. Also, this patient already has a severe metabolic acidosis. In this circumstance, antidotal therapy to block alcohol dehydrogenase with ethanol or 4-MP alone is insufficient to treat the poisoning. Data suggest that a severe lactic acidosis needs initial correction and in this patient the most appropriate treatment would be IV fluids with bicarbonate to correct the metabolic acidosis. Then haemodialysis is probably required.

[Q: 1228] OnExamination - Clinical pharmacology

Which of the following are centrally acting antihypertensive therapies?

- 1- Hydralazine
- 2- Minoxidil
- 3- Moxonidine
- 4- Phenoxybenzamine
- 5- Verapamil

Answer & Comments

Answer: 3- Moxonidine

Moxonidine and alpha-methyl dopa are centrally acting antihypertensives and modify blood pressure through central action modifying sympathetic activity. Verapamil is a calcium antagonist, minoxidil and hydralazine both vasodilators and phenoxybenzamine an alpha blocker.

[Q: 1229] OnExamination - Clinical pharmacology

Which of the following mechanisms best explains the action of Ezetimibe?

- 1- Activation of PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 5- Inhibits cholesterol absorption

Ezetimibe localises at the brush border of the small intestine, where it inhibits the absorption of cholesterol from the diet.

[Q: 1230] OnExamination - Clinical pharmacology

A 30-year-old male presented with a paranoid psychosis accompanied by visual hallucinations which resolved over the next three days.

Which one of the following is the most likely diagnosis?

- 1- Alcohol withdrawal.
- 2- Diazepam dependence.
- 3- Fluoxetine overdose.
- 4- Heroin withdrawal.
- 5- Smoking cannabis.

Answer & Comments

Answer: 1- Alcohol withdrawal.

The paranoid psychosis with visual hallucinations is highly suggestive of delirium tremens - alcohol withdrawal.

[Q: 1231] OnExamination - Clinical pharmacology

A 68-year-old lady with mitral valve disease and atrial fibrillation is taking warfarin. Lately her INR has fallen and the dose of warfarin has had to be increased.

Which of the following new treatments may account for this change?

- 1- Allopurinol
- 2- Amiodarone
- 3- Clarithromycin
- 4- Sertraline
- 5- St John's wort

Answer & Comments

Answer: 5- St John's wort

The metabolism of warfarin has been increased since it is becoming less effective. St John's Wort is an enzyme inducer. The other drugs are enzyme inhibitors.

[Q: 1232] OnExamination - Clinical pharmacology

A 72-year-old man is discharged from hospital following a stroke. During his stay he was started on several new medications. He presents with diarrhoea.

Which of the following medications is most likely to be the cause?

- 1- Clopidogrel
- 2- Enalapril
- 3- Metformin
- 4- Pioglitazone
- 5- Simvastatin

Answer & Comments

Answer: 3- Metformin

Although all the medications listed could cause gastrointestinal disturbances it is metformin that is by far the most likely.

[Q: 1233] OnExamination - Clinical pharmacology

Which of the following are correct concerning an Intention To Treat analysis?

- 1- It is a variation of a meta-analysis analysing specifically studies employing double blind placebo controlled trials.
- 2- It is a study where all included patients are treated with the active drug.
- 3- It is a study where all non-compliant patients are removed from analysis.
- 4- It is a study that analyses all patients randomised to the study.
- 5- It is a study comparing the effects of treatment with placebo or active treatment and also a similar group of non-study participants.

Answer & Comments

Answer: 4- It is a study that analyses all patients randomised to the study.

When one considers a randomised study, although the principles of double blind placebo controlled may apply, the actual preferential fall out of patients, for instance treated with placebo as they do not perceive a benefit, may itself introduce bias. Thus, Intention to Treat studies would argue that one should commit all patients that originally participate in the study to analysis.

The advantages of this approach are that it maintains treatment groups that are similar apart from random variation. This is the reason for randomisation, and the feature may be lost if analysis is not performed on the groups produced by the randomisation process. Secondly, it permits for non-compliance and deviations from policy by clinicians.

[Q: 1234] OnExamination - Clinical pharmacology

Which one of the following is correct regarding long-acting beta-2 agonists?

- 1- Can be used to prevent activity-induced symptoms without anti-inflammatory therapy.

- 2- Become less effective over time (tolerance).
- 3- Are beneficial in acute viral croup.
- 4- Protect against allergen challenge for up to 48 hours.
- 5- Should not be used in association with erythromycin.

Answer & Comments

Answer: 1- Can be used to prevent activity-induced symptoms without anti-inflammatory therapy.

Long-acting beta-2 agonists, e.g. salmeterol, can be used twice daily to assist in prophylaxis in chronic asthma as Step 3 of the British Thoracic Society Asthma Guidelines. There is no evidence that the bronchodilator effect wanes with time, though there is debate that it may become less effective in protecting against exercise or methocoline induced bronchospasm. Its duration of action is around 12 hours, and has gone completely by 36 hours. Aminophylline interacts with erythromycin, giving an increased risk of toxicity. There is no evidence that salmeterol works in viral croup, though oral steroids are highly effective.

[Q: 1235] OnExamination - Clinical pharmacology

A 65-year-old lady with a history of recurrent DVT. She has been weaned off her warfarin and started on intravenous heparin prior to cardiac bypass for ischaemic heart disease. She seems to require very high doses of heparin to achieve adequate anticoagulation especially during surgery.

Which of the following conditions would explain her thrombophilia and her heparin resistance?

- 1- Activated Protein C resistance
- 2- Antithrombin III deficiency
- 3- Lupus anticoagulant

- 4- Protein C deficiency
- 5- Protein S deficiency

Answer & Comments

Answer: 2- Antithrombin III deficiency

"Cardiac surgery produces a unique activation of coagulation due to the presence of the cardiopulmonary bypass (CPB) circuit. Whilst not yet fully elucidated, the mechanisms of activation of coagulation during CPB may involve activation of fX by the tissue factor-mediated pathway within the pericardial cavity, in addition to direct generation of fXa on the surface of monocytes by Cathepsin G, a substance released from activated monocytes. The inhibition of fXa in these situations involves the AT-dependent mechanism of action of heparin."

[Q: 1236] OnExamination - Clinical pharmacology

A 55-year-old female has recently commenced Leflunomide for sero-negative rheumatoid arthritis. At baseline, prior to commencing the drug, her AST was 33 iu/l and her ALT was 40 iu/l. She attends for routine blood monitoring. Her FBC is normal but her liver function tests reveal:

AST 58 iu/l (5 - 40 iu/l)

ALT 71 iu/l (7 - 45 iu/l)

Alkaline Phosphatase 100 iu/l (50 - 120 iu/l)

Bilirubin 12 micromol/l (5 - 18 iu/l)

What is the most appropriate management option for this patient?

- 1- Continue Leflunomide and monitor LFTs in one month
- 2- Continue Leflunomide and monitor LFTs in two weeks
- 3- Stop Leflunomide and commence washout procedure.
- 4- Stop Leflunomide and seek urgent rheumatological advice.

- 5- Stop the Leflunomide and repeat tests in two weeks.

Answer & Comments

Answer: 5- Stop the Leflunomide and repeat tests in two weeks.

Leflunomide is associated with serious hepatotoxicity. Increased aminotransferases are commonly seen in association with therapy occurring in 15-20% of cases (less than a two fold rise). However, more serious elevation (greater than 3 fold) is seen in less than 5%. Generally, most hepatic events occur within the first six months of use. Guidelines suggest that where there is a less than 2 fold elevation of transaminases, the drug should be stopped and the LFT repeated in two weeks. If the results have returned to normal then the drug can be recommenced.

As the active drug has such a long half life (approx 15 days), in patients with severe elevations of LFTs, wash out treatment may be required to assist in excretion/reduce absorption of the drug. This includes Cholestyramine and activated Charcoal.

[Q: 1237] OnExamination - Clinical pharmacology

A 42-year-old man presents with gingival hypertrophy.

Which of his cardiac medications is likely to be responsible?

- 1- Amlodipine
- 2- Atenolol
- 3- Digoxin
- 4- GTN
- 5- Simvastatin

Answer & Comments

Answer: 1- Amlodipine

Calcium channel blockers and drugs like phenytoin and cyclosporin are associated with gingival hypertrophy.

[Q: 1238] OnExamination - Clinical pharmacology

A 50-year-old male has a blood pressure of 160/90 on two consecutive days. You decide that you are going to initiate drug therapy.

Which of the following statements regarding your decision is correct?

- 1- An alpha-blocker would be a first line agent in this patient
- 2- Spironalactone would be an appropriate second line agent in this patient
- 3- If the patient is non-caucasian, a beta-blocker would be an appropriate first line treatment
- 4- Potassium monitoring is not required if an ACE inhibitor is prescribed without the addition of spironalactone
- 5- ACE inhibitors should not be used as first line treatment in Afro-Caribbean patients

Answer & Comments

Answer: 5- ACE inhibitors should not be used as first line treatment in Afro-Caribbean patients

ACE inhibitors have low efficacy in black patients in the clinical trials of ACE inhibitors. According to the British Hypertension Society guidelines (J Hum Hypertension 2003;17:81-86) first line treatment in black patients, and patients greater than 55 years of age, should be with a diuretic or a calcium channel blocker. An alpha blocker or spironalactone should only be used as an adjunct treatment in resistant hypertension

[Q: 1239] OnExamination - Clinical pharmacology

A 62-year-old male is prescribed Sildenafil for impotence.

What is the mechanism of action through which Sildenafil works?

- 1- Central Dopaminergic agent
- 2- Guanylate cyclase agonist
- 3- Nitric oxide synthase agonist
- 4- Phosphodiesterase inhibitor
- 5- Selective alpha-sympathetic inhibitor

Answer & Comments

Answer: 4- Phosphodiesterase inhibitor

Sildenafil is a phosphodiesterase 5 inhibitor. Inhibition of this enzyme results in an accumulation of nitric oxide in the cavernosal veins resulting in venodilation and facilitating an erection.

[Q: 1240] OnExamination - Clinical pharmacology

Which of the following mechanisms best explains the action of OMACOR (omega-3-acid ethyl esters)?

- 1- Activation of PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 4- Increases peroxisomal beta-oxidation of fatty acids

Omacor reduces triglycerides by different, independent effects in the liver. The synthesis of triglycerides is inhibited through reduced production of triglycerides in the liver, as EPA and DHA are poor substrates for the enzymes

responsible for triglyceride synthesis. EPA and DHA also inhibit esterification of other fatty acids. Omacor increases peroxisomal beta-oxidation of fatty acids in the liver.

[Q: 1241] OnExamination - Clinical pharmacology

A 16-year-old female is admitted after taking an overdose of her mother's propranolol tablets approximately 2 hours ago. On examination she is drowsy and has a pulse of 40 beats per minute with a blood pressure of 80/40 mmHg. She is treated with activated charcoal, IV fluids and IV atropine but her bradycardia and hypotension fail to respond.

Which of the following would be the most appropriate next stage in her management?

- 1- IV adrenaline
- 2- IV amiodarone
- 3- IV glucagon
- 4- IV Phenytoin
- 5- Insertion of temporary pacemaker

Answer & Comments

Answer: 3- IV glucagon

In those in whom initial atropine is unsuccessful, IV Glucagon is a recommended treatment for β -blocker overdose with some evidence indicating improvement in bradycardia and blood pressure.

[Q: 1242] OnExamination - Clinical pharmacology

A 42-year-old man presented with confusion following a seizure. He has a history of epilepsy and is also known to the community psychiatry team. Examination reveals that he has a temperature of 37°C, BP 138/84, coarse tremor and a pulse of 90 bpm.

Which of the following is the most likely underlying diagnosis?

- 1- Benzodiazepine overdose

- 2- Carbamazepine toxicity
- 3- Lithium toxicity
- 4- Neuroleptic malignant syndrome
- 5- Tricyclic overdose

Answer & Comments

Answer: 3- Lithium toxicity

The tremor, seizure and confusion should raise the possibility of Lithium toxicity which is the condition that best fits this clinical picture.

[Q: 1243] OnExamination - Clinical pharmacology

A 50-year-old man presented with a milky discharge from his nipples. He had a history of depression and gastro-oesophageal reflux disease and was on a number of medications.

Plasma Prolactin 650 mU/L (< 360)

Which of the following is the most likely cause of his symptoms?

- 1- Amitryptiline
- 2- Cimetidine
- 3- Fluoxetine
- 4- Metoclopramide
- 5- Omeprazole

Answer & Comments

Answer: 4- Metoclopramide

This man has galactorrhoea and raised prolactin. The most likely culprit is metoclopramide through its action on dopamine. It release prolactin through dopamine antagonism.

[Q: 1244] OnExamination - Clinical pharmacology

A 70-year-old man presents with an episode of syncope. On subsequent investigation he is found to have marked postural hypotension. He has been taking felodipine for

hypertension for a number of years and he also takes aspirin. On further questioning he appears to have taken up a new healthier lifestyle on his seventieth birthday.

Which of the following health supplements is he most likely to have taken that would have contributed to the calcium-channel blocker induced hypotension?

- 1- Cranberry juice
- 2- Cod liver oil capsules
- 3- Ginseng
- 4- Grapefruit juice
- 5- Vitamin C

Answer & Comments

Answer: 4- Grapefruit juice

Grapefruit juice interacts with drugs. The basis for this interaction has been diligently explored and appears to relate to both flavanoid and nonflavanoid components of grapefruit juice interfering with enterocyte CYP3A4 activity. Of the calcium channel blockers felodipine in particular is affected. Am J Hypertens (2006) 19: 768-73

[Q: 1245] OnExamination - Clinical pharmacology

In which of the following would the first drug be associated with increased pharmacological action of the second drug?

- 1- Erythromycin : theophylline
- 2- Phenytoin : ethinyloestradiol
- 3- Ranitidine : corticosteroid
- 4- Rifampicin : warfarin
- 5- Valproate : phenobarbitone

Answer & Comments

Answer: 1- Erythromycin : theophylline

Erythromycin would inhibit the metabolism of theophylline. Ranitidine unlike Cimetidine is

not an enzyme inhibitor. Phenytoin would speed up metabolism of Ethinyl-Oestradiol making the pill less effective. Rifampicin is a well recognised enzyme inducer.

[Q: 1246] OnExamination - Clinical pharmacology

Which of the following pharmacological agents acts through the opening of potassium channels?

- 1- Amiloride
- 2- Glibenclamide
- 3- Lidocaine
- 4- Nicorandil
- 5- Phenytoin

Answer & Comments

Answer: 4- Nicorandil

Nicorandil is a potent potassium channel activator. It relaxes vascular smooth muscle through membrane hyperpolarization via increased transmembrane potassium conductance and, like nitrates, through an increase in intracellular cyclic GMP. Glibenclamide blocks potassium channels. Amiloride inhibits the action of aldosterone on the distal convoluted tubule producing potassium reabsorption.

[Q: 1247] OnExamination - Clinical pharmacology

A 23-year-old man with known peanut allergy presented to the Emergency department with anaphylaxis. He has a swollen face and lips. His BP is 90/60, pulse 110 bpm and he is wheezy.

Which of the following formulations of adrenaline should be given?

- 1- 0.5 ml of 1:10000 adrenaline IM
- 2- 0.5 ml of 1:1000 adrenaline IM
- 3- 5 ml of 1:1000 adrenaline IM
- 4- 10 ml of 1:10000 adrenaline IV

- 5- Nebulised adrenaline

Answer & Comments

Answer: 2- 0.5 ml of 1:1000 adrenaline IM

"For adults, a dose of 0.5 mL adrenaline 1:1000 solution (500 micrograms) should be administered intramuscularly, and repeated after about 5 minutes in the absence of clinical improvement or if deterioration occurs after the initial treatment especially if consciousness becomes - or remains - impaired as a result of hypotension. In some cases several doses may be needed, particularly if improvement is transient." Resuscitation Council UK

Adult Epipen which allergy sufferers can carry with them contains 0.3 mg adrenaline in a 1:1000 dilution for IM injection.

[Q: 1248] OnExamination - Clinical pharmacology

A middle aged lady presents with cervical and inguinal lymphadenopathy. She is also experiencing pins and needles in glove and stocking distribution. She had previous of epilepsy and was under regular medication.

Which of the following drugs is most likely to cause her symptoms?

- 1- Carbamazepine
- 2- Phenobarbitone
- 3- Phenytoin
- 4- Sodium valproate
- 5- Vigabatrin

Answer & Comments

Answer: 3- Phenytoin

Recognized side effects of phenytoin include drowsiness, ataxia, confusion, blurred vision, dizziness, nystagmus, permanent cerebellar ataxia, peripheral neuropathy, rashes, gum hypertrophy, thickening of the facial features,

lymphadenopathy, chorea, and sleep disturbance. Remarkable side effects of other anti-epileptic drugs are: drowsiness, blurred vision, dizziness, leucopenia, SIADH and rash (carbamazepine), liver toxicity (sodium valproate), severe rash (lamotrigine), retinal damage (vigabatrin) and aplastic anemia (felbamate).

[Q: 1249] OnExamination - Clinical pharmacology

Which of the following regarding Infliximab is most true

- 1- Is a monoclonal antibody to the glycoprotein IIb-IIIa receptor
- 2- Is authorised for the treatment of severe ulcerative colitis
- 3- Is licensed for the treatment of rheumatoid arthritis
- 4- It prevents relapse of Crohn's disease in patients who are in remission
- 5- Must not be used in combination with methotrexate due to increased toxicity

Answer & Comments

Answer: 3- Is licensed for the treatment of rheumatoid arthritis

Infliximab is a monoclonal antibody to TNF alpha. It is licensed for the treatment of:- (1). Severe active Crohn's disease refractory to corticosteroid or immunosuppressant therapy and for refractory fistulas. (2). Rheumatoid arthritis in adults whose response to disease-modifying antirheumatic drugs has been inadequate. Before starting therapy and throughout treatment, patients should be evaluated carefully for tuberculosis as there have been reports of the onset or reactivation of TB including miliary TB and some unusual extrapulmonary TB. Infliximab must be given concomitantly with methotrexate and requires IV infusion in a hospital setting. Some other monoclonal antibodies in clinical use

include (1)Digibind - digoxin-binding antibody for treatment of overdoses (increases clearance); (2)Abciximab: glycoprotein IIb/IIIa receptor (for unstable angina); (3)Pexelizumab: anti-C5 (complement) - anti-inflammatory: reduces MI and death following CABG.)

[Q: 1250] OnExamination - Clinical pharmacology

45-year-old woman has taken an unknown quantity of Amitriptyline tablets that were being prescribed for her depression approximately four hours ago. She is feeling drowsy, agitated and has a dry mouth. An ECG shows wide QRS complexes with arrhythmias.

Blood Gas Analysis revealed

pH 7.2

paO₂ 10 KPa (11-13)

paCO₂ 4 KPa (4.7-6)

What is the most appropriate treatment?

- 1- Activated Charcoal
- 2- Gastric Lavage
- 3- Haemodialysis
- 4- Intravenous Insulin
- 5- Intravenous Sodium Bicarbonate

Answer & Comments

Answer: 5- Intravenous Sodium Bicarbonate

There is no specific treatment for Tricyclic antidepressant poisoning. 500 ml of 1.26% sodium bicarbonate should be used to treat arrhythmias, hypotension and significant ECG abnormalities to a pH of 7.50 - 7.55 in Tricyclic antidepressant overdose even in the absence of acidosis.

[Q: 1251] OnExamination - Clinical pharmacology

A 52-year-old woman who complains of exertional breathlessness presents to the

clinic as she is desperate to stop smoking. She has had a number of unsuccessful attempts to stop smoking over the years and has tried nicotine patches.

Which of the following would be an appropriate choice to assist in her attempts at smoking cessation?

- 1- Acupuncture
- 2- Hypnotism
- 3- Nicotine gum
- 4- Nortriptyline
- 5- Varenicline

Answer & Comments

Answer: 5- Varenicline

Varenicline (Champix) is an oral anti-smoking agent with dual action, reducing the craving for cigarettes and also making the smoking of cigarettes less pleasurable. ASH - action on smoking and health have released guidance on its use. It appears to be effective and safe with the main side effect being nausea.

Varenicline appears to be more effective in clinical trials than either bupropion or placebo and is prescribed for 12 weeks in the first instance with further 12 week course if craving still persists.

[Q: 1252] OnExamination - Clinical pharmacology

A 59-year-old male presents with a three day history of marked muscle aches and weakness. He has ischaemic heart disease for which he takes a number of drugs including simvastatin and has been taking these drugs for a number of years without any problem. On this occasion his CPK confirms a diagnosis of rhabdomyolysis with a level of 4200 iu/l (<200).

Which of the following health supplements is he most likely to have taken that would have

contributed to the statin-induced rhabdomyolysis?

- 1- Cranberry juice
- 2- Cod liver oil capsules
- 3- Ginseng
- 4- Grapefruit juice
- 5- Vitamin C

Answer & Comments

Answer: 4- Grapefruit juice

Grapefruit juice is well recognised to inhibit statin metabolism thereby potentiating the myotoxicity. In particular, grapefruit juice should be avoided with simvastatin and lovastatin and it also inhibits metabolism of calcium channel blockers and theophylline.

[Q: 1253] OnExamination - Clinical pharmacology

Which of the following antiemetics functions as a cholinergic muscarinic antagonist?

- 1- Aprepitant
- 2- Domperidone
- 3- Hyoscine
- 4- Metoclopramide
- 5- Ondansetron

Answer & Comments

Answer: 3- Hyoscine

Scopolamine is named after the genus Scopolia. The name "hyoscine" is from the scientific name for henbane, Hyoscyamus niger. It acts as a competitive antagonist at muscarinic acetylcholine receptors; it is thus classified as an anticholinergic or as an anti-muscarinic drug.

[Q: 1254] OnExamination - Clinical pharmacology

A 59-year-old male type 2 diabetic is attending

the foot clinic regularly. He has a neuropathic ulcer complicated by osteomyelitis a deep wound swab has grown Staphylococcus aureus and E coli. He also takes warfarin for atrial fibrillation.

Which of the following antibiotics will reduce the anticoagulant effect of Warfarin?

- 1- Ciprofloxacin
- 2- Co-trimoxazole
- 3- Erythromycin
- 4- Metronidazole
- 5- Rifampicin

Answer & Comments

Answer: 5- Rifampicin

The anticoagulant effect of warfarin can be affected by drugs, which induce or inhibit the action of enzymes involved in the metabolism of warfarin. Rifampicin is known to induce the action of such enzymes therefore increasing the metabolism of warfarin so reducing its anticoagulant effect. Erythromycin and ciprofloxacin inhibit the effect of these enzymes therefore enhancing the anticoagulant effect of warfarin.

Metronidazole and Co-trimoxazole inhibit the clearance of the active S isomer of warfarin therefore enhancing its anticoagulant effect.

[Q: 1255] OnExamination - Clinical pharmacology

A 40-year-old man has a hygienist appointment with his dentist for scaling. He is known to have a congenital bicuspid aortic valve.

Which of the following is the most appropriate form of prophylaxis against endocarditis?

- 1- Amoxicillin 1g IV + gentamicin 120mg IV pre-procedure
- 2- Amoxicillin 3g PO pre-procedure
- 3- Gentamicin 120mg IM pre-procedure

- 4- Metronidazole 1g PO pre-procedure
- 5- No antibiotics required

Answer & Comments

Answer: 2- Amoxicillin 3g PO pre-procedure

Although often asymptomatic and affecting 1 - 2% of the population bicuspid aortic valve is a risk factor for endocarditis and later development of aortic valve disease. If known, patients should receive antibiotic prophylaxis.

[Q: 1256] OnExamination - Clinical pharmacology

A 17-year-old female presents to A+E following self-confessed paracetamol poisoning after discovering she is 8 weeks pregnant and had a row with her boyfriend. She claims to have taken an approximately 30 paracetamol tablets approximately 58 hours ago. Her history is considered to be reliable. There are no abnormalities to find on examination. Her blood sugar by finger prick testing was 3.1 mmol/l.

Which of the following would be the most appropriate treatment for this patient?

- 1- Haemodialysis
- 2- Intravenous dextrose infusion
- 3- Intravenous N-acetylcysteine
- 4- Oral activated charcoal
- 5- Oral vitamin K

Answer & Comments

Answer: 3- Intravenous N-acetylcysteine

Irrespective of the pregnancy, this girl should receive n-acetyl cysteine. Paracetamol concentration is unhelpful in delayed presentation of paracetamol overdose. A dose of >150mg/kg is considered to be toxic and toxicity occurs at a lower concentration if the patient is thought to be in high risk group. Clotting screen (INR), liver function tests, acid-

base balance and plasma glucose should be taken without delay prior to starting treatment with N-acetylcysteine. Serial monitoring of clotting screen is required and N-acetylcysteine should continue until INR returns to normal. Further advice on treatment of complicated cases should be sought from National Poisons Information Service. Other supportive treatment is guided by the patients condition.

[Q: 1257] OnExamination - Clinical pharmacology

In a chronic disease which has no known effective treatment, a new treatment is known to be effective in animal models and shows promise in short-term studies in patients.

There are some theoretical concerns about toxicity involving liver and bone marrow although no cases have been observed in studies so far.

What is the most appropriate next step in the drug's development?

- 1- case control study
- 2- No further studies should be done and drug development should be stopped
- 3- open study
- 4- randomised double blind placebo controlled study
- 5- randomised single blind placebo controlled study

Answer & Comments

Answer: 4- randomised double blind placebo controlled study

The story that is described is of an early drug development that has gone through phase I trials (normal volunteers) and phase two studies (more normal volunteers but it also mentions 'studies in patients'). The next step in the development of this drug is a phase 3 study - where the drug's efficacy and safety

should be tested against a placebo. Take a look at this pdf file for a good description of drug development.

[Q: 1258] OnExamination - Clinical pharmacology

A 45-year-old female with chronic schizophrenia was recently converted to a new anti-psychotic agent. She presented two weeks later with a sore throat and fever.

Her full blood count shows:

Haemoglobin 12.5 g/dl

White cell count $1.3 \times 10^9/L$

Platelets $135 \times 10^9/L$

What drug is she likely to have commenced?

- 1- Clozapine
- 2- Haloperidol
- 3- Olanzapine
- 4- Quetiapine
- 5- Risperidone

Answer & Comments

Answer: 1- Clozapine

Unlike the other newer antipsychotic agents, Clozapine is associated with agranulocytosis in approximately 1-2% of patients. The mechanism through which this happens remains unclear.

[Q: 1259] OnExamination - Clinical pharmacology

A 45-year-old female attend the clinic complaining of headache and vomiting for 5 days. She has a history of scleroderma complicated by stage V chronic kidney disease. On examination, she is tachycardic and has a blood pressure of 240/130mmhg; funduscopy reveals grade 3 hypertensive retinopathy.

Which of the following is a centrally acting antihypertensive agent.

- 1- Diazoxide
- 2- Hydralazine
- 3- Minoxidil
- 4- Moxonidine
- 5- Sodium nitroprusside

Answer & Comments

Answer: 4- Moxonidine

Moxonidine is centrally acting and is licensed for mild to moderate hypertension not controlled by beta blockers, ACE inhibitors, calcium channel antagonists and thiazides. Moxonidine is a selective agonist at the imidazoline subtype 1 receptor. This receptor subtype is found in the medulla oblongata. Moxonidine causes a decrease in sympathetic nervous system activity and, therefore, a decrease in blood pressure.

The other drugs listed are vasodilator in action. Diazoxide, and sodium nitroprusside can be used intravenously in hypertensive emergencies. Minoxidil is reserved for when hypertension is resistant to other treatments; it causes fluid retention and oedema, however, it is effective in combination with a β -blocker and loop diuretic. Hydralazine can be given orally also in combination with a diuretic and β -blocker; side effects include reflex tachycardia and fluid retention.

[Q: 1260] OnExamination - Clinical pharmacology

A clinical trial assessing a new lipid lowering therapy for stroke allocates 1000 patients to active treatment and another 1000 patients to placebo. Results demonstrate that number needed to treat (NNT) is 20 for the prevention of the primary end-point.

Which of the following best describes the results?

- 1- 20 patients in the treatment group were protected from stroke.

- 2- 20 extra patients in the placebo group had a stroke
- 3- For 1000 patients treated with active therapy, there would be 20 fewer strokes
- 4- For 1000 patients treated with active therapy, there would be 50 fewer strokes.
- 5- For every 1000 patients treated with active therapy there would be 100 fewer strokes

Answer & Comments

Answer: 4- For 1000 patients treated with active therapy, there would be 50 fewer strokes.

This prevention study for stroke reveals that 20 patients need to be treated to prevent one event. Thus if you treat a 1000 patients then you will expect to have 50 fewer strokes.

[Q: 1261] OnExamination - Clinical pharmacology

A 55-year-old man with type 2 diabetes has noticed elevation of his blood glucose levels on a new treatment for his lipids. He says his diet and exercise levels are unchanged; his HbA1c has also deteriorated by about 0.5%.

Which one of the following drugs is the likely cause?

- 1- cholestyramine
- 2- ezetimibe
- 3- fenofibrate
- 4- nicotinic acid
- 5- rosuvastatin

Answer & Comments

Answer: 4- nicotinic acid

The mechanism of the effect of nicotinic acid on glucose is not entirely clear but, in some patients, it may increase blood glucose. For the majority of patients with diabetes it has a minimal effect.

"Since nicotinic acid inhibits hepatic triglyceride synthesis the increased availability of free fatty acids may stimulate hepatic glucose output, either directly or indirectly. Free fatty acids are known to stimulate gluconeogenesis. Alternatively, free fatty acids may replace glucose as a primary energy source, enhancing glucose output by the liver. Another theory holds that free fatty acids rebound above baseline levels following initial suppression by nicotinic acid, blocking glucose uptake by skeletal muscle. Direct effects on beta-cell function have also been postulated, although there is no evidence to support this." Br J Diabetes Vasc Dis 2004;4:7885

[Q: 1262] OnExamination - Clinical pharmacology

A 60-year-old female suffers from bipolar affective disorder and is being treated with Lithium. She also has a long history of hypertension for which she is on treatment. During a recent clinic visit her blood pressure was noted to be 170/94 mmHg and a new antihypertensive agent was added. A week later she presents with features of Lithium toxicity including tremor, nausea and weakness.

The addition of which one of the following drugs was likely to have precipitated the Lithium toxicity?

- 1- Doxazosin
- 2- Hydralazine
- 3- Lisinopril
- 4- Minoxidil
- 5- Moxonidine

Answer & Comments

Answer: 3- Lisinopril

The precipitation of Lithium toxicity by diuretics is well appreciated. Yet ACE inhibitors and Angiotensin Antagonists are also capable of precipitating Lithium toxicity

through reduced Lithium clearance. Other drugs that may precipitate Lithium toxicity include NSAIDs, tetracycline, phenytoin and ciclosporin.

[Q: 1263] OnExamination - Clinical pharmacology

A 52-year-old lady presented with a history of crushing central chest pain, sweating and dyspnoea. An ECG confirms acute myocardial infarction with ST elevation in leads V2 - V4 and ST depression in leads II and III.

Which of the following would be a contraindication to thrombolysis in this lady?

- 1- History of peptic ulcer disease
- 2- Intracranial neoplasm
- 3- Menstruation
- 4- Pre-proliferative diabetic retinopathy
- 5- Stroke 6 months previously

Answer & Comments

Answer: 2- Intracranial neoplasm

Contraindications to thrombolysis include intracranial neoplasm as here, stroke in the last 2 months, pregnancy, active internal bleeding, aortic dissection, recent significant head injury, severe and uncontrolled hypertension.

[Q: 1264] OnExamination - Clinical pharmacology

A 33-year-old woman with a history of alcoholism and self-neglect, presents with an episode of blood streaked vomiting. This is attributed to minor Mallory-Weiss tear. She is admitted to hospital and given an intravenous infusion of 5% dextrose. Her serum potassium concentration is noted the following day to have fallen to 1.9mmol/L (NR 3.5-4.9mmol/L) on admission.

What is the likely mechanism for the fall in potassium concentration?

- 1- Cortisol release in response to stress increasing renal potassium loss
- 2- Decompensated liver failure causing aldosterone secretion
- 3- Intracellular re-uptake in response to re-feeding with glucose
- 4- Metabolic acidosis increasing renal potassium excretion
- 5- Potassium levels falling following gastric loss in vomiting

Answer & Comments

Answer: 3- Intracellular re-uptake in response to re-feeding with glucose

This neglected person is being fed with dextrose, which will cause an elevation of circulating insulin to maintain glycaemic control. This will consequently drive potassium intracellularly so reducing extracellular potassium concentration.

[Q: 1265] OnExamination - Clinical pharmacology

Which of the following drugs interacts with cranberry juice?

- 1- Amiodarone
- 2- Digoxin
- 3- Propranolol
- 4- Simvastatin
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

This is a pathetic question but apparently this theme has been asked in the exam. I suspect that the authors of this were the culprits in composing this question. The answer is warfarin.

[Q: 1266] OnExamination - Clinical pharmacology

A 45-year-old male takes Lithium for a bipolar affective disorder.

Which of the following drugs would be contra-indicated in conjunction with Lithium?

- 1- Atenolol
- 2- Bendroflumethiazide
- 3- Codeine Phosphate
- 4- Flucloxacillin
- 5- Thyroxine

Answer & Comments

Answer: 2- Bendroflumethiazide

Caution should be exercised when taking as the latter may reduce renal clearance of lithium and increase serum lithium concentrations. NSAIDs also increase Lithium concentrations. Metronidazole, ACEis and Calcium channel blockers also increase serum Lithium concentrations.

[Q: 1267] OnExamination - Clinical pharmacology

Which of the following antiemetics functions through antagonism of the 5-hydroxytryptamine 3A receptor?

- 1- Aprepitant
- 2- Domperidone
- 3- Hyoscine
- 4- Metoclopramide
- 5- Ondansetron

Answer & Comments

Answer: 5- Ondansetron

Ondansetron is a serotonin 5-HT₃ receptor antagonist used mainly to treat nausea and vomiting following chemotherapy. Its effects are thought to be on both peripheral and central nerves. One part is to reduce the

activity of the vagus nerve, which is a nerve that activates the vomiting center in the medulla oblongata, the other is a blockage of serotonin receptors in the chemoreceptor trigger zone. It does not have much effect on vomiting due to motion sickness. This drug does not have any effect on dopamine receptors or muscarinic receptors.

[Q: 1268] OnExamination - Clinical pharmacology

An 85-year-old woman presented with bilateral osteoarthritis of the knees. She had no history of previous gastrointestinal disease.

Which of the following is the most appropriate initial treatment for her?

- 1- Celecoxib
- 2- Naproxen
- 3- Dihydrocodeine
- 4- Paracetamol
- 5- Topical diclofenac.

Answer & Comments

Answer: 4- Paracetamol

The recommendations of the American College of Rheumatology published in Arthritis and Rheumatism 2000, recommend acetaminophen (paracetamol) together with non-pharmacological interventions (exercise, diet) as first line therapy of mild/moderate OA of hips or knees.

[Q: 1269] OnExamination - Clinical pharmacology

A 40-year-old ex-footballer presents requesting treatment for alcoholism and is prescribed disulfiram.

What is the mode of action of Disulfiram?

- 1- Decreases severity of alcohol withdrawal
- 2- Helps alcoholics to drink safely

- 3- Inhibits acetaldehyde dehydrogenase activity
- 4- Inhibits alcohol dehydrogenase activity
- 5- Reduces the desire for alcohol

Answer & Comments

Answer: 3- Inhibits acetaldehyde dehydrogenase activity

Alcohol is mainly metabolized in the liver to acetaldehyde by alcohol dehydrogenase. Acetaldehyde is then oxidized to acetate by acetaldehyde dehydrogenase (AcDH). Disulfiram irreversibly inhibits the oxidation of acetaldehyde by competing with the cofactor nicotinamide adenine dinucleotide (NAD) for binding sites on (AcDH). The increased acetaldehyde levels are thought to produce the unpleasant side effects associated with acetaldehyde syndrome such as headaches, nausea, flushing etc.

[Q: 1270] OnExamination - Clinical pharmacology

A 60-year-old lady develops a fracture of the wrist following a fall; DEXA scan reveals osteoporosis in lumbar spine and hip. She has been commenced on once weekly Alendronate 70 mg daily and also takes a calcichew tablet.

By what mechanism does the Bisphosphonate function in the treatment of osteoporosis?

- 1- Enhancing the absorption of calcium from the gut
- 2- Enhancing the absorption and action of vitamin D
- 3- Enhancing the survival and function of osteoblasts
- 4- Enhancing the survival and function of osteoclasts
- 5- Reducing the survival and function of osteoclasts

Answer & Comments

Answer: 5- Reducing the survival and function of osteoclasts

Osteoclasts are responsible for bone resorption; therefore by reducing the efficacy of osteoclasts bone turnover is reduced. Bisphosphonates licensed for the prevention and treatment of osteoporosis include Alendronate, Risedronate and Ibandronate. The bisphosphonates Zoledronate and Pamidronate are used for the treatment of metastatic bone disease and short-term management of hypercalcaemia.

[Q: 1271] OnExamination - Clinical pharmacology

A 50-year-old man is being treated for hypertension and has been told that he has gingival hyperplasia by his dentist.

Which of the following medications is the most likely to be the cause?

- 1- Atorvastatin
- 2- Carvedilol
- 3- Doxazosin
- 4- Nifedipine
- 5- Telmisartan

Answer & Comments

Answer: 4- Nifedipine

Three drugs to remember that are associated with gingival hyperplasia are phenytoin, ciclosporin and nifedipine.

[Q: 1272] OnExamination - Clinical pharmacology

A 54-year-old man is found to have a prolonged corrected QT interval on his ECG.

Which of the following drugs is the most likely cause?

- 1- Cefaclor

2- Digoxin

3- Moxonidine

4- Sotalol

5- Telmisartan

Answer & Comments

Answer: 4- Sotalol

Sotalol, amiodarone, Class 1a antiarrhythmic drugs, tricyclic antidepressants, chloroquine and terfenadine are causes of drug-induced long QT.

[Q: 1273] OnExamination - Clinical pharmacology

A 51-year-old female has rheumatoid arthritis. She states that she is allergic to Penicillin and Co-Trimoxazole.

Therefore, which of the following drugs is contraindicated?

- 1- Azathioprine
- 2- Ciclosporin
- 3- Gold therapy
- 4- Methotrexate
- 5- Sulphasalazine

Answer & Comments

Answer: 5- Sulphasalazine

Both co-trimoxazole and sulphasalazine contain sulphonamide groups and hence an allergy to co-trimoxazole would be a contraindication to the use of sulphasalazine. Co-trimoxazole is a mixture of trimethoprim and sulfamethoxazole. Sulphasalazine is a combination of 5-aminosalicylic acid and sulfapyridine.

[Q: 1274] OnExamination - Clinical pharmacology

A 48-year-old lady with a history of epilepsy and ischaemic heart disease presented with

the following Full Blood Count.

Haemoglobin $7.4 \times 10^9/L$ (11.5 - 16.5)

Mean cell volume 125 fL (80 - 96)

White cell count $2.5 \times 10^9/L$ (4 - 11)

Platelet count $130 \times 10^9/L$ (150 - 400)

Which of the following medications is the most likely cause?

- 1- Carbamazepine
- 2- Clopidogrel
- 3- Furosemide
- 4- Phenytoin
- 5- Spironolactone

Answer & Comments

Answer: 4- Phenytoin

There is a macrocytic anaemia with low platelets and WCC typical of a nutritional deficiency. Phenytoin can lead to folate deficiency and is therefore the most likely cause.

[Q: 1275] OnExamination - Clinical pharmacology

A 72-year-old lady presented after taking an overdose of a sustained-release propranolol preparation. She has a pulse of 40 bpm and a BP of 90/60. She was given atropine by the Emergency department staff but there has been little response.

Which of the following is the most appropriate treatment?

- 1- Atropine
- 2- Glucagon
- 3- Haemodialysis
- 4- Noradrenaline
- 5- Salbutamol

Answer & Comments

Answer: 2- Glucagon

"For cases of β -blocker poisoning where symptomatic bradycardia and hypotension are present, high-dose glucagon is considered the first-line antidote."

[Q: 1276] OnExamination - Clinical pharmacology

A young boy is born with a heart murmur that is subsequently diagnosed as Ebstein's anomaly.

Which of the following drugs, taken by the mother, may have contributed to this case of congenital heart disease?

- 1- Amiodarone
- 2- Carbimazole
- 3- Lithium
- 4- Phenytoin
- 5- Warfarin

Answer & Comments

Answer: 3- Lithium

Exposure to Lithium in-utero is associated with Ebstein's anomaly.

[Q: 1277] OnExamination - Clinical pharmacology

Which of the following mechanisms best explains the action of simvastatin?

- 1- Activation of PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 3- Decreases hepatic cholesterol synthesis

Most circulating cholesterol is manufactured internally, in amounts of about 1000 mg/day, via carbohydrate metabolism through the HMG-CoA reductase pathway. Statins act by competitively inhibiting HMG-CoA reductase, the first committed enzyme of the HMG-CoA reductase pathway.

[Q: 1278] OnExamination - Clinical pharmacology

A 56-year-old female who is taking warfarin for atrial fibrillation and has had a stable INR of between 2-2.5 over the last one year is noted to have an INR on the last visit of 7.8.

Consumption of which of the following may be responsible for this?

- 1- Carrot juice
- 2- Cranberry juice
- 3- Oil of evening primrose
- 4- Orange juice
- 5- St John's wort

Answer & Comments

Answer: 2- Cranberry juice

has been recognised to be responsible for a deranged INR, it being postulated that it inhibits cytochrome p450. St John's wort induces cytoP450 and therefore reduces INR

[Q: 1279] OnExamination - Clinical pharmacology

A 51-year-old man presents with wheals and urticaria. He takes a variety of medications.

Which drug is the most likely to have caused this reaction?

- 1- Aspirin
- 2- Glyceryl trinitrate
- 3- Omeprazole
- 4- Paracetamol
- 5- Simvastatin

Answer & Comments

Answer: 1- Aspirin

The most likely cause of an urticarial eruption from this list would be aspirin. Other drugs frequently associated with urticaria include NSAIDs, penicillin, ACE inhibitors, thiazides and codeine.

[Q: 1280] OnExamination - Clinical pharmacology

There is presently no known effective treatment for a chronic disease. A new treatment is known to be effective in animal models and shows promise in short-term studies in patients. There is some theoretical concerns regarding possible hepato- and bone marrow toxicity although thus far, no toxicity have been observed in studies.

What is the most appropriate next step in the drug's development?

- 1- A case control study
- 2- No further studies should be done and drug development should be stopped
- 3- An open study
- 4- A randomised double blind placebo controlled study
- 5- A randomised single blind placebo controlled study

Answer & Comments

Answer: 4- A randomised double blind placebo controlled study

It appears that the drug has undergone animal testing and we can surmise that it has also been tested on normal volunteers (phase 1) as we are told that it has been tried in short-term studies of patients (phase 2). After this testing process comes phase 3 studies - Broad clinical trials designed to determine whether the drug is of clinical benefit in the disease state. In particular you wish to know whether the drug is effective or not and you wish to know its

safety. A double blind placebo controlled study would be best placed to provide this information.

[Q: 1281] OnExamination - Clinical pharmacology

A 90-year-old man with chronic leukaemia presents with gout which his general practitioner treats with Allopurinol.

How does Allopurinol prevent the accumulation of uric acid?

- 1- By competing for its transporter to the kidney
- 2- By enhancing its solubility
- 3- By inhibiting purine synthesis
- 4- By inhibiting pyrimidine synthesis
- 5- By inhibiting the inflammatory response it causes

Answer & Comments

Answer: 3- By inhibiting purine synthesis

Allopurinol is a xanthine oxidase inhibitor and is converted by this enzyme to alloxanthine in this form it inhibits the conversion of hypoxanthine to xanthine, and the conversion of xanthine to uric acid. Therefore inhibiting the formation of uric acid.

[Q: 1282] OnExamination - Clinical pharmacology

A 16-year-old female is admitted with a severe paracetamol overdose. She is treated with IV N-acetylcysteine.

By replenishing which of the following compounds does N-acetylcysteine function as an antidote in paracetamol overdose?

- 1- Arginine
- 2- Cysteine
- 3- Cystine
- 4- Glutathione

5- Methionine

Answer & Comments

Answer: 4- Glutathione

Paracetamol is predominantly metabolised to glucuronide and sulphate conjugates, which are excreted in the urine. Hepatotoxicity is related to the conversion of a small proportion of the ingested dose to N-acetyl-p-benzoquinoneimine. In therapeutic doses N-acetyl-p-benzoquinoneimine is detoxified by conjugation with glutathione in the liver, but once the protective intracellular glutathione stores are depleted hepatic and renal damage may ensue. and Methionine replenishes glutathione stores in the liver and may also act through its Sulphydryl (-SH) group as a direct reducing agent.

[Q: 1283] OnExamination - Clinical pharmacology

A 48-year-old man is admitted with nausea and excessive drowsiness after taking an antihistamine tablet. He has previously used the antihistamine but on this occasion he has recently been drinking large amounts of grapefruit juice for his health.

Grapefruit juice is suspected of causing a drug interaction in this man.

Which of the following liver enzyme systems is affected by grapefruit juice?

- 1- Cytochrome p450 3A4
- 2- Glycine decarboxylase
- 3- Glucuronidation
- 4- Glutathione S-transferase
- 5- Sulfation

Answer & Comments

Answer: 1- Cytochrome p450 3A4

Bergamottin is a constituent of grapefruit juice and is metabolised by the Cytochrome p450 3A4 pathway.

[Q: 1284] OnExamination - Clinical pharmacology

A 60-year-old lady presented with heartburn. She is known to have osteoporosis and has been taking alendronate for a number of years.

Which of the following is the most likely cause of her symptoms?

- 1- Achalasia
- 2- Calcification of lower oesophageal sphincter
- 3- Crush fracture
- 4- Ischaemic heart disease
- 5- Oesophagitis

Answer & Comments

Answer: 5- Oesophagitis

"Oral bisphosphonates seem to induce serious esophagitis in some patients, may result in gastritis and cause diarrhea. When used as recommended, serious esophageal complications are few. Patients with known esophageal disease (e.g., achalasia, stricture, Barrett's esophagus, severe reflux and scleroderma) should avoid taking oral bisphosphonates." Am Fam Physician 2000;61:2731-6

[Q: 1285] OnExamination - Clinical pharmacology

A 60-year-old man has left ventricular failure and clinically he is classified as NYHA Class III. He takes furosemide, aspirin and ramipril.

The addition of which one of the following betablockers would be expected to further improve his prognosis?

- 1- Acebutolol
- 2- Bisoprolol

- 3- Esmolol
- 4- Propranolol
- 5- Sotalol

Answer & Comments

Answer: 2- Bisoprolol

Bisoprolol is a highly selective beta(1)-adrenoceptor antagonist. Administration of bisoprolol to patients with chronic heart failure is associated with increases in left ventricular function and reductions in heart rate; increases in heart rate variability are also seen. Two major randomised, double-blind, placebo-controlled, multicentre trials have examined the clinical efficacy of bisoprolol in combination with ACE inhibitors and diuretics in patients with stable chronic heart failure (New York Heart Association class III or IV).

[Q: 1286] OnExamination - Clinical pharmacology

A 55-year-old woman is attending clinic a number of months after having had a myocardial infarction. She has been commenced on appropriate drugs to reduce cardiovascular risk and has made dietary modifications for healthy living. Recently, however, she complains of muscle aches and pains and is found to have an elevated CPK.

Consumption of which of the following is likely to have contributed to increased statin-associated myotoxicity?

- 1- Carrot juice
- 2- Cranberry juice
- 3- Garlic cloves
- 4- Grapefruit juice
- 5- Omega-3 fish oils

Answer & Comments

Answer: 4- Grapefruit juice

Grapefruit juice significantly increases serum concentrations of some statins. This is achieved by reducing the CYP3A4-mediated first-pass metabolism in the small intestine. On the other hand, grapefruit juice has no effect on the pharmacokinetics of pravastatin, Rosuvastatin and fluvastatin. Concomitant use of atorvastatin and large amounts of grapefruit juice should be avoided, or the dose of atorvastatin should be reduced accordingly. CYP3A4 is a member of the cytochrome P450 system. (Clin Pharmacol Ther 1999;66:118-27. Cranberry juice may speed up metabolism of liver enzymes and hence may cause problems with reduced warfarin efficacy.

[Q: 1287] OnExamination - Clinical pharmacology

A 48-year-old lady with Addison's disease presented in a small peripheral clinic. She says that she has run out of her hydrocortisone and she usually takes 20 mg in the morning and 10 mg in the evening. No hydrocortisone is available at the clinic but you do have prednisolone which you would like to prescribe instead until a prescription of hydrocortisone can be dispensed.

What is the equivalent daily dose of prednisolone?

- 1- 2.5 mg
- 2- 5 mg
- 3- 7.5 mg
- 4- 10 mg
- 5- 20 mg

Answer & Comments

Answer: 3- 7.5 mg

1 mg is equivalent to 4 mg hydrocortisone so this lady should be given 7.5 mg. If 2.5 mg tablets were not available (to go with a 5 mg tablet to make 7.5 mg tablet) then 10 mg would be fine. It is better to overdose rather

than under-dose especially where there is stress or illness.

[Q: 1288] OnExamination - Clinical pharmacology

A 68-year-old lady presents to her GP for an annual review of her heart failure treatment. She has a blood pressure of 165/90. She is currently taking furosemide and aspirin and she dyspnoea on walking up hills..

Which of the following is the most appropriate medication to add?

- 1- Bendroflumethiazide
- 2- Enalapril
- 3- Isosorbide mononitrate
- 4- Spironolactone
- 5- Titrate dose of furosemide

Answer & Comments

Answer: 2- Enalapril

ACE inhibitors remain one of the cornerstones of the treatment of heart failure [SOLVD and CONSENSUS trials]. There is clear evidence that higher doses exert greater benefit. They are usually very well tolerated, especially in milder cases. ()

[Q: 1289] OnExamination - Clinical pharmacology

Which one of the following drugs works by inhibiting the tumour necrosis factor?

- 1- cyclosporin
- 2- infliximab
- 3- methotrexate
- 4- montelukast
- 5- sulphasalazine

Answer & Comments

Answer: 2- infliximab

Montelukast works as leukotriene receptor antagonists, and is used in treatment of asthma. Etanercept and infliximab inhibit TNF and are licensed in the treatment of rheumatoid arthritis. Infliximab is given with methotrexate and is associated with development of tuberculosis.

[Q: 1290] OnExamination - Clinical pharmacology

An 18-year-old woman is admitted after taking drugs at a night-club.

Which of the following features suggest she had taken Ecstasy (MDMA)?

- 1- A pyrexia of 40oC
- 2- hypernatraemia
- 3- hypokalaemia
- 4- metabolic acidosis
- 5- respiratory depression

Answer & Comments

Answer: 1- A pyrexia of 40oC

Hyponatraemia, tachycardia, hyperventilation and hyperthermia are features of the amphetamine MDMA abuse.

[Q: 1291] OnExamination - Clinical pharmacology

A 72-year-old man presents with painful lumps in his feet and is diagnosed with gout. Following initial treatment with non-steroidal anti-inflammatory agents he is started on Allopurinol.

How does this work?

- 1- Inhibits macrophage tubular formation
- 2- Inhibits cyclooxygenase II
- 3- Inhibits nitric oxide synthase
- 4- Inhibits xanthine oxidase
- 5- Increases urinary uric acid excretion

Answer & Comments

Answer: 4- Inhibits xanthine oxidase

Allopurinol inhibits xanthine oxidase, the enzyme involved in the conversion of purines into uric acid.

[Q: 1292] OnExamination - Clinical pharmacology

A 70-year-old man presented with increasing dyspnoea. In his history, he had suffered a myocardial infarction two years previously which had been complicated by ventricular arrhythmias. At admission his oxygen saturations were 85% on air and a chest X-ray revealed bilateral patchy infiltration of both lung fields with a cardiothoracic ratio of 20/30 cm.

Which of the following drugs that he has been prescribed is most likely to explain these findings?

- 1- Amiodarone
- 2- Atorvastatin
- 3- Aspirin
- 4- Furosemide
- 5- Ramipril

Answer & Comments

Answer: 1- Amiodarone

This patient has desaturation with patchy infiltration on CXR suggesting a diagnosis of amiodarone-induced lung disease. Usually the presentation is insidious and the disorder associated with the cumulative dose. Treatment depends on withdrawing amiodarone and initiation of steroid therapy. Differential diagnosis is any lymphangitis/pneumonitis but High resolution CT can help by demonstration of radio-dense plaques etc.

[Q: 1293] OnExamination - Clinical pharmacology

A 52-year-old female with a three year history of sero-positive erosive rheumatoid arthritis has recently commenced methotrexate therapy initiated at the rheumatology clinic.

Which of the following agents should she also be receiving in conjunction with her Methotrexate?

- 1- Folic acid
- 2- Omeprazole
- 3- Thiamine
- 4- Vitamin C
- 5- Zinc supplements

Answer & Comments

Answer: 1- Folic acid

Methotrexate is a chemotherapeutic agent as well as being an immunosuppressant used as a DMARD. It acts through inhibition of dehydrofolate reductase thus depleting folate concentrations. To reduce the impact of folate deficiency, a dose of 5mg of folic acid weekly* is recommended in conjunction with methotrexate taking the agent at least two days prior to commencing the methotrexate. Its action in arthritides is not entirely understood but may relate to both anti-inflammatory as well as immunomodulation.

*Some local variations may exist regarding dose and frequency of folate therapy. Please be aware of your local guidelines.

[Q: 1294] OnExamination - Clinical pharmacology

A 60-year-old male who has been prescribed lisinopril for hypertension presents with an irritating cough.

What is the mechanism responsible for ACE-induced cough?

- 1- Angiotensin I accumulation

- 2- Asthma
- 3- Bradykinin accumulation
- 4- Laryngeal irritation
- 5- Renin accumulation

Answer & Comments

Answer: 3- Bradykinin accumulation

The enzyme ACE is also responsible for the metabolism of bradykinin in mast cells. The accumulation of this substance is responsible for the cough found in up to 30% of subjects taking ACE-inhibitors. This phenomenon is not seen in subjects taking Angiotensin receptor blockers such as Losartan.

[Q: 1295] OnExamination - Clinical pharmacology

A 46-year-old male was seen for an insurance medical examination. He was entirely asymptomatic, but his serum urate concentration was noted to be 0.5 mmol/L (0.23 - 0.46).

What is the most appropriate management for this patient?

- 1- Allopurinol
- 2- Colchicine
- 3- Ibuprofen
- 4- Lifestyle intervention
- 5- Sulphinpyrazone

Answer & Comments

Answer: 4- Lifestyle intervention

This asymptomatic patient requires only lifestyle advice i.e weight loss if appropriate, an appropriate diet and reduction of alcohol.

[Q: 1296] OnExamination - Clinical pharmacology

A 45-year-old male attends for an insurance medical and is in good health. Examination

was normal but investigations reveal that he has a serum urate concentration of 0.55 mmol/l (NR 0.25-0.45).

Which of the following is the most appropriate management for this patient?

- 1- Lifestyle advice
- 2- Start Allopurinol
- 3- Start Colchicine
- 4- Start Diclofenac
- 5- Start Prednisolone

Answer & Comments

Answer: 1- Lifestyle advice

The most appropriate treatment for this asymptomatic man with an isolated slightly elevated urate is lifestyle advice with an appropriately reduced purine diet, increased exercise and reduced alcohol consumption.

[Q: 1297] OnExamination - Clinical pharmacology

A 17-year-old female presents with acute breathlessness. She has had asthma for approximately 3 years and recently commenced new therapy.

Which agent may be responsible for this exacerbation?

- 1- Salmeterol
- 2- Theophylline
- 3- Beclomethasone
- 4- Ipratropium bromide
- 5- Monteleukast

Answer & Comments

Answer: 1- Salmeterol

Salmeterol has been reported to produce an acute exacerbation of asthma, possibly through an acute hypersensitivity reaction.

[Q: 1298] OnExamination - Clinical pharmacology

You are asked to advise on analgesia for a 44-year-old woman with acute intermittent porphyria who has undergone wisdom teeth extraction.

Which of the following drugs is safe for use in her treatment?

- 1- Cephalexin
- 2- Cetirizine
- 3- Diclofenac
- 4- Erythromycin
- 5- Ibuprofen

Answer & Comments

Answer: 5- Ibuprofen

Many drugs may induce acute porphyric crises, thus great care must be taken when prescribing for patients with acute porphyria. Drugs unsafe for use in acute porphyria include barbiturates, tricyclic antidepressants, MAOIs, amphetamines, anabolic steroids, hormone replacement therapy, benzodiazepines, diuretics, captopril, cephalosporins, erythromycin, isoniazid, sulphonamides, sulphonylureas, theophylline, antihistamines, nifedipine, verapamil, amiodarone and simvastatin. Ibuprofen is safe for use in acute intermittent porphyria, but diclofenac should be avoided.

[Q: 1299] OnExamination - Clinical pharmacology

Hypomagnesaemia may be caused by which of the following drugs?

- 1- Aminophylline
- 2- Cisplatin
- 3- Co-trimoxazole
- 4- Digoxin
- 5- Amitriptyline

Answer & Comments

Answer: 2- Cisplatin

Thiazide diuretics (not mentioned here) are a common cause of reduced serum magnesium. Cisplatin is a well recognised cause of hypomagnesaemia.

[Q: 1300] OnExamination - Clinical pharmacology

The following are causes of drug induced hepatitis except:

- 1- Amiodarone
- 2- Ethambutol
- 3- Isoniazid
- 4- Methyldopa
- 5- Pyrazinamide

Answer & Comments

Answer: 2- Ethambutol

Side effects of ethambutol are largely confined to visual disturbances in form of loss of acuity, colour blindness and restriction of visual fields. It does not cause hepatitis and is renally excreted. Isoniazid, amiodarone, pyrazinamide and methyldopa are a cause of drug induced hepatitis.

[Q: 1301] OnExamination - Clinical pharmacology

A 45-year-old female presents with a 6 month history of exertional dyspnoea and is diagnosed with pulmonary fibrosis. Over the last one year she has received a variety of medications.

Which of the following drugs could be responsible?

- 1- Dexamethasone
- 2- Ibuprofen
- 3- nalidixic acid
- 4- penicillamine

5- sulphasalazine

Answer & Comments

Answer: 5- sulphasalazine

Sulphasalazine as well as other rheumatology drugs such as Gold, Methotrexate can cause pulmonary fibrosis. Bleomycin and Cyclophosphamide rather than vincristine may be responsible. Corticosteroids are sometimes given as a trial in pulmonary fibrosis. Nalidixic acid is associated with seizures and visual disturbances. However nitrofurantoin is well recognised to cause PF.

Other drugs include amiodarone and nitrofurantoin

[Q: 1302] OnExamination - Clinical pharmacology

A study has been designed to investigate whether a certain drug plus physiotherapy treatment is better than drug treatment alone in the management of rheumatoid arthritis. After randomizing the patients a small proportion of the drug plus physiotherapy group decide to drop out of the study or omit some treatment sessions specified in the research protocol.

What is the correct way of analysing the subsequent data?

- 1- Assume the patients have withdrawn their consent
- 2- Exclude these patients from all analysis
- 3- Extend the trial recruitment to make up the numbers
- 4- Include these patient outcomes in the drug plus physiotherapy group
- 5- Interview the patients and report their group separately

Answer & Comments

Answer: 4- Include these patient outcomes in the drug plus physiotherapy group

This is the principle of 'intention to treat'. It is possible that the physiotherapy intervention was harmful to the patients and this is why they left. Intention to treat helps to reduce bias by sticking to the original allocation of treatment and analyzing the patient in that treatment group even (and concentrate for this bit) even if they don't get it!

[Q: 1303] OnExamination - Clinical pharmacology

A 63-year-old female presents with dry mouth of 3 months duration. She is taking medication for hypertension, stress incontinence and reflux oesophagitis.

Which of the following may be responsible for her dry mouth?

- 1- Oxybutinin
- 2- Doxazosin
- 3- Hydrallazine
- 4- Cimetidine
- 5- Bendroflumethiazide

Answer & Comments

Answer: 1- Oxybutinin

Oxybutinin is an effective treatment for detrusor instability and is a parasympathetic muscarinic antagonist. Consequently dry mouth is a problem in up to 70% of cases. Bendroflumethiazide, the thiazide diuretic, at a dose of 2.5 mg per day is not associated with dry mouth. Cimetidine is a H₂ antagonist and is not associated with dry mouth.

[Q: 1304] OnExamination - Clinical pharmacology

With regard to poisoning / overdose:

- 1- Phenobarbitone causes a metabolic acidosis
- 2- Ethylene glycol causes a metabolic alkalosis and renal failure

3- Aspirin causes acidosis due to hypoventilation

4- Methanol causes a metabolic acidosis with an increased anion gap

5- Chlormethiazole causes hyperthermia and hypertension

Answer & Comments

Answer: 4- Methanol causes a metabolic acidosis with an increased anion gap

Aspirin causes hyperventilation which may result in a respiratory alkalosis, massive overdose may cause a metabolic acidosis. Phenobarbitone & Chlormethiazole both suppress the CNS causing hypoventilation, hypotension & hypothermia. Ethylene glycol causes a metabolic acidosis. Methanol is metabolised to formaldehyde and formic acid.

[Q: 1305] OnExamination - Clinical pharmacology

A 48-year-old female with rheumatoid arthritis has the following full blood count results:

Haemoglobin 11.4 g/dl (12-16.5)

Platelets 470 x 10⁹/L (150-450)

White Cell Count 9.0 x 10⁹/L (4-10)

MCV 102 fl (83-95)

Which drug is she likely to be taking?

- 1- Ciclosporin
- 2- Hydroxychloroquine
- 3- Leflunomide
- 4- Methotrexate
- 5- Mycristin

Answer & Comments

Answer: 4- Methotrexate

Leflunomide is associated rarely with anaemia, thrombocytopenia and eosinophilia. Ciclosporin may be associated

with a mild anaemia. Methotrexate may be associated with haematopoietic suppression, leading to profound, and sometimes sudden leucopenia and thrombocytopenia.

Methotrexate may lead to macrocytosis as a result of B12 or folate deficiency. Myocristin may also rarely lead to blood disorders, pancytopenia and leucopenia. The elevated platelet count here probably relates to the rheumatoid arthritis itself.

[Q: 1306] OnExamination - Clinical pharmacology

In which of the following have randomised controlled trials shown that long-term oxygen therapy (LTOT) reduces mortality?

- 1- Asthma
- 2- Cor pulmonale due to chronic airflow obstruction
- 3- Cryptogenic fibrosing alveolitis
- 4- Cystic fibrosis
- 5- Pulmonary sarcoidosis

Answer & Comments

Answer: 2- Cor pulmonale due to chronic airflow obstruction

Adequate data for LTOT prolonging survival exists only for COPD although in practice it is assumed to apply in other chronic hypoxaemic lung conditions.

[Q: 1307] OnExamination - Clinical pharmacology

Which of the following most accurately describes the mechanism of action of the bisphosphonates?

- 1- Calcium resorption in the distal tubule
- 2- Fibroblast proliferation in bone marrow
- 3- Improved vascular supply to bone marrow
- 4- Inhibition of osteoclast activity

- 5- Upregulation of osteoblast activity

Answer & Comments

Answer: 4- Inhibition of osteoclast activity

The mechanism of action of alendronate and risedronate, as well as newer

agents, involves the inhibition of the pathway that leads to the production of certain essential lipid compounds inside osteoclasts, resulting in a series of events leading to decreased osteoclast activity and to the induction of cell death

[Q: 1308] OnExamination - Clinical pharmacology

A new drug is being studied to find the most appropriate dose in a dose response study. Small doses of the drug lead to a linear increase in serum drug concentration. At higher doses there is an exponential rise in serum drug concentration.

Which of the following best describes the pharmacokinetic properties of this new drug?

- 1- first order kinetics [25]
- 2- first pass effect
- 3- long plasma half life
- 4- saturation kinetics
- 5- zero order kinetics [25]

Answer & Comments

Answer: 4- saturation kinetics

The description of the kinetics of this new drug show that with small doses there is a linear response (first order kinetics) to dosing but this becomes saturated and the serum concentration of the drug rises sharply (zero order kinetics). This response is typical of drugs such as phenytoin (saturates liver metabolism).

[Q: 1309] OnExamination - Clinical pharmacology

Lead poisoning:

- 1- Causes adrenal suppression
- 2- Can only result from lead ingestion
- 3- Is associated with a macrocytic anaemia
- 4- Causes a peripheral neuropathy due to demyelination
- 5- Commonly presents with diarrhoea

Answer & Comments

Answer: 4- Causes a peripheral neuropathy due to demyelination

Lead can also be absorbed through the skin and by inhalation. Associated with iron deficiency & a microcytic anaemia. Most common GI symptoms are abdominal colic and constipation.

[Q: 1310] OnExamination - Clinical pharmacology

A 29-year-old man who is a keen amateur photographer with his own development studio presented to the Emergency department with confusion. His partner said he had been under a great deal of stress recently and she found him foolishly drinking a developer solution with a poison symbol on it. He is hypoxic and hypotensive. The local poisons unit suggests a diagnosis of cyanide poisoning.

Which of the following would be the most appropriate treatment?

- 1- Desferrioxamine
- 2- Dicobalt EDTA
- 3- Gastric lavage with Fuller's earth
- 4- Haemodialysis
- 5- Penicillamine

Answer & Comments

Answer: 2- Dicobalt EDTA

Potassium ferricyanide is used chiefly for blueprints, in photography, for staining wood, in calico printing, and in electroplating.

Kelocyanor (dicobalt EDTA), given by intravenous injection, has been proven to be of use when administered to seriously ill victims of confirmed cyanide poisoning. It is itself toxic, however, and can kill if used wrongly. HSE knows of several cases of inappropriate use resulting in hospital treatment. Its administration is beyond the scope of first aid and a recommendation has been made in the past that a 'Kelocyanor kit' should be kept by users of cyanide and transported to hospital with the patient. Unfortunately we are aware of cases where this has misled doctors to treat patients for cyanide poisoning when this diagnosis was not correct.

[Q: 1311] OnExamination - Clinical pharmacology

A farmer, on treatment for depression is admitted acutely 1 hour following an intentional overdose of an unidentified substance. On examination he is bradycardic, hypotensive, disorientated, hypersalivating, and has small pupils.

He has most likely ingested :

- 1- Paracetamol
- 2- A tricyclic anti-depressant
- 3- Paraquat
- 4- An organophosphate insecticide
- 5- Cyanide

Answer & Comments

Answer: 4- An organophosphate insecticide

Hypersalivation and miosis are the specific clues to acetylcholine overactivity.

Occupational access to organophosphate insecticides. Pupils tend to be dilated with TCA OD. Paracetamol, cyanide, and paraquat shouldn't affect pupils.

[Q: 1312] OnExamination - Clinical pharmacology

A 35-year-old man is admitted following a serious attempt of paracetamol overdose. Despite efforts to treat him he develops liver failure.

Which of the following is most likely with the ensuing liver failure?

- 1- It is harmful to give N-acetylcysteine
- 2- better prognosis in those with high alcohol consumption
- 3- hypoglycaemia rarely happens within 12 hours of onset of encephalopathy
- 4- lactic acidosis is recognised complication
- 5- better prognosis in older patients

Answer & Comments

Answer: 4- lactic acidosis is recognised complication

Use of intravenous N-acetylcysteine reduces morbidity and mortality in fulminant hepatic failure. Severe hypoglycaemia affects 40% of patients with fulminant liver failure, which exacerbates encephalopathy. It may develop rapidly and recur with sepsis. Lactic acidosis due to decreased hepatic lactate clearance, compounded by poor peripheral perfusion and increased lactate production. Poor prognosis in those with blood pH<7.0, prolonged prothrombin time (>100s) and serum creatinine >300uM. Mortality is greater if patient > 40 years of age.

[Q: 1313] OnExamination - Clinical pharmacology

A 63-year-old man was found collapsed. A Department of Psychiatry outpatient Card was

found in his jacket, together with a bottle of procyclidine tablets. He was febrile (38.2°C), conscious but unresponsive to commands. The blood pressure was 160/105 mmHg and there was marked muscle rigidity.

What is the most likely diagnosis?

- 1- acute catatonic schizophrenia
- 2- bacterial meningitis
- 3- cerebral malaria
- 4- neuroleptic malignant syndrome
- 5- procyclidine overdose

Answer & Comments

Answer: 4- neuroleptic malignant syndrome

The symptoms are typical of neuroleptic malignant syndrome (NMS). NMS is characterized by fever, muscular rigidity, altered mental status, and autonomic dysfunction. Procyclidine is used to treat the Parkinsonian side-effects of neuroleptics: its presence in the patient's pocket implies that he was taking neuroleptics. Signs of procyclidine overdose include agitation, confusion, and sleeplessness lasting up to 24 hours or more. Pupils are dilated and unreactive to light. Visual and auditory hallucinations and tachycardia have also been reported.

[Q: 1314] OnExamination - Respiratory

A 40-year-old worker presents with wheezing and breathlessness which seem to improve over weekends and holiday periods when he is not working.

What is he most likely to be exposed to at work?

- 1- Platinum salts
- 2- Avian bloom
- 3- Aspergillus clavatus
- 4- Work in the Silver industry
- 5- Exposure to spores of Actinomyces

Answer & Comments

Answer: 1- Platinum salts

Disinfectants and preservatives including glutaraldehyde, chlorhexidine and formaldehyde can cause occupational asthma. Metals causing occupational asthma include isocyanates cobalt, aluminium, chrome, manganese, nickel, zinc, and platinum. Exposure to Actinomyces (farmer's lung, mushroom workers' lung), avian bloom (bird fanciers' lung) and aspergillus clavatus (malt worker's lung) cause extrinsic allergic alveolitis.

[Q: 1315] OnExamination - Respiratory

Which of the following statements regarding cryptogenic fibrosing alveolitis is correct?

- 1- Active inflammation may be suggested by a CT scan
- 2- peak flow rate is a good guide to severity
- 3- 80 per cent of patients initially respond well to immunosuppression
- 4- peak incidence seen in the fourth decade
- 5- lung volumes show a raised residual volume / total lung capacity ratio

Answer & Comments

Answer: 1- Active inflammation may be suggested by a CT scan

a - also the presence of a predominantly ground glass appearance is an independent predictor of survival.

b - Peak flow measure airway obstruction. CFA is characterised by a restrictive defect on lung function testing.

c - About 50% of patients have an improvement in their symptoms with steroids and 25% have improved lung function.

d - peak incidence is in the 6th decade

e - residual volume (RV) increases with airways obstruction, total lung capacity (TLC) reduces with restrictive disorders like CFA. A raised RV/TLC ratio suggests a combination of airways obstruction and restrictive defect NOT just CFA as mentioned in this question.

[Q: 1316] OnExamination - Respiratory

Which of the following statements is NOT true of primary pulmonary tuberculosis:

- 1- It is characteristically asymptomatic
- 2- Miliary spread is commoner in a younger age group
- 3- The initial immunological response causes hilar lymphadenopathy
- 4- pleural effusion occurs before tuberculin skin testing is positive
- 5- A positive tuberculin skin test develops within two weeks of infection

Answer & Comments

Answer: 5- A positive tuberculin skin test develops within two weeks of infection

Primary TB is usually asymptomatic, with miliary TB most likely to occur in young children. The Ghon focus is the area of

consolidation from cellular infiltration and response to uptake of organisms by macrophages, which transform into epithelioid cells and group into granulomata. Bacilli are transported via lymphatics early in disease process to regional lymph nodes to cause marked lymphadenopathy. Positive tuberculin test occurs between 3 weeks to 3 months after primary infection. Pleural and pericardial infections occur at or shortly after primary infection.

[Q: 1317] OnExamination - Respiratory

A lifelong non-smoker is diagnosed with emphysema.

Which of the following would be the most likely aetiological agent ?

- 1- Isocyanates
- 2- Cadmium Exposure
- 3- Steel
- 4- Zinc
- 5- Asbestos

Answer & Comments

Answer: 2- Cadmium Exposure

Cadmium fume inhalation is a recognised cause of emphysema. Other industrial associations with COPD include coal, cotton, grain and cement.

[Q: 1318] OnExamination - Respiratory

In restrictive lung disease due to respiratory muscle weakness, which of the following statements is true?

- 1- Low FEV₁/FVC, high RV/TLC
- 2- Low FEV₁/FVC, normal TLC
- 3- Low VC, low FEV₁, normal TLC, low RV/TLC
- 4- Low VC, low RV, low TLC
- 5- Low VC, low TLC, high RV/TLC

Answer & Comments

Answer: 5- Low VC, low TLC, high RV/TLC

The lung is itself can function normally yet muscle weakness will result in grossly low lung volumes including FEV₁, FVC and TLC. However residual volume will be relatively high as a consequence of this weakness. Consequently, RV/TLC will be elevated. However the transfer of carbon monoxide (TCO) will be unaffected.

[Q: 1319] OnExamination - Respiratory

Which of the following is found in subjects acclimatised to life at high altitudes ?

- 1- Increased mean corpuscular haemoglobin concentration
- 2- Increased pulmonary artery pressure
- 3- Periodic respiration
- 4- Reduced cardiac output
- 5- Reduced airway resistance

Answer & Comments

Answer: 2- Increased pulmonary artery pressure

discriminating question! Acclimatisation results in increased Hb with erythrocytosis. Periodic respiration is a feature of non-acclimatisation. Respiration is normal when subjects are acclimatised to altitude as is cardiac output. Pulmonary artery pressure increases in an effort to oxygenate more blood. 2,3-DPG increases.

[Q: 1320] OnExamination - Respiratory

A 36-year-old man complains of a persistent cough. A CXR shows fibrosis of both upper lobes.

What is the most likely diagnosis?

- 1- Systemic Sclerosis
- 2- Primary Pulmonary Hypertension

- 3- Cystic Fibrosis
- 4- Ankylosing Spondylitis
- 5- Allergic bronchopulmonary aspergillosis

Answer & Comments

Answer: 5- Allergic bronchopulmonary aspergillosis

The persistent cough is likely to be a symptom of asthma. On the other hand, only about 1% of patients with advanced ankylosing spondylitis develop apical fibrosis ie rare . Even then, early lesions are asymptomatic. It is when only when cavitation develops that symptoms like cough, infected sputum and haemoptysis start. With ABPA, fibrosis and loss of volume in the upper lobes are common. Within these upper lobes, there may be bronchiectasis.

[Q: 1321] OnExamination - Respiratory

Which of the following is a typical feature of Farmer's lung?

- 1- basal crackles
- 2- Eosinophilia
- 3- Haemoptysis
- 4- Increased pCO₂
- 5- Positive serum paraproteins

Answer & Comments

Answer: 1- basal crackles

Commonest occupational extrinsic allergic alveolitis, due to thermophilic actinomycetes. Crackles are typically heard at the bases. Eosinophilia can be seen but is not typical. Immunoglobulin levels are frequently elevated but not a paraprotein. P_{O2} may be decreased particularly with exercise. A restrictive pattern on LF studies is seen.

[Q: 1322] OnExamination - Respiratory

A 25-year-old male presents to A+E with shortness of breath. One week ago, he developed influenza and has become more short of breath and fatigued in the last 24 hours. His temperature is 38.5°C, his SaO₂ is 90% on 2L of oxygen, a blood pressure 100/60 mmHg and heart rate 120/min. The CXR shows patchy consolidation.

Which antibiotic therapy should you select for this man?

- 1- Amoxicillin
- 2- Amoxicillin and Flucloxacillin
- 3- Amoxicillin and Gentamicin
- 4- Amoxicillin and Rifampicin
- 5- Flucloxacillin

Answer & Comments

Answer: 2- Amoxicillin and Flucloxacillin

Patients who present with pneumonia after influenzae or measles are at risk of Staphylococcal pneumonia. Look for cavitation on the CXR. The BTS guidelines: state that amoxicillin should be first line therapy for all pneumoniae, with the addition of flucloxacillin if there is risk of it being staphylococcal. Gentamicin may be indicated in severe hospital acquired pneumonia, and rifampicin in severe atypical infections (e.g. legionella).

[Q: 1323] OnExamination - Respiratory

Which of the following is NOT true with regard to the radiological appearance of a chest X-ray?

- 1- Consolidation of the right middle lobe will obliterate the right atrial shadow in the PA view
- 2- Consolidation of the right apical segment will extend to the horizontal fissure in the PA view

- 3- Consolidation of the right anterior segment of the right middle lobe will extend to the right transverse fissure and the right hilum in PA view
- 4- Consolidation of the lingular lobe will obliterate the aortic knuckle and pulmonary trunk in the PA view
- 5- Consolidation of the left lower lobe will elevate the left hemidiaphragm

Answer & Comments

Answer: 5- Consolidation of the left lower lobe will elevate the left hemidiaphragm

Consolidation in left lower lobe obliterates the diaphragm, whilst lingular consolidation will obliterate the left heart border. Oblique fissure runs obliquely at 45° from T4 or 5 vertebra to anterior costophrenic angle on lateral chest film. The horizontal fissure runs from the hilum anteriorly to anterior chest wall. The area above the horizontal fissure is upper lobe, below the horizontal fissure is the middle lobe and below the oblique fissure is the lower lobe.

[Q: 1324] OnExamination - Respiratory

A 25-year-old woman is admitted with a 4-month history of cough productive of mucoid sputum streaked with bright red blood, wheezing and diarrhoea. Her chest and abdominal examination is normal.

Which of the following investigation is the most discriminatory?

- 1- Bronchoscopy
- 2- Chest X-ray
- 3- Computed tomography (CT) of chest
- 4- Echocardiogram
- 5- Ventilation-perfusion scan

Answer & Comments

Answer: 1- Bronchoscopy

Bronchial carcinoid is a highly vascular 'cherry-like' tumour causing recurrent haemoptysis and bronchial obstruction. It may rarely produce the classical symptoms of carcinoid syndrome such as cyanotic flushings, intestinal cramps and diarrhoea following liver metastases in 5% cases. Bronchoscopy identifies up to 80% of carcinoid tumours in the main bronchi. Biopsy is usually followed with brisk bleeding and should be done via rigid bronchoscopy.

[Q: 1325] OnExamination - Respiratory

A 29-year-old professional singer presents with a prolonged history of epistaxis and rapidly progressive shortness of breath. The KCO and eosinophil count are raised.

Which of the following is the most likely diagnosis?

- 1- Goodpasture's syndrome
- 2- Microscopic polyangiitis
- 3- Churg-Strauss syndrome
- 4- Wegener's granulomatosis
- 5- Alveolar proteinosis

Answer & Comments

Answer: 4- Wegener's granulomatosis

The patient with breathlessness and a raised KCO has alveolar haemorrhage until proven otherwise. A prolonged history of epistaxis or sinusitis is commonly found in Wegener's granulomatosis, which in some patients is also associated with an eosinophilia. A history of asthma must usually be present to diagnose the Churg-Strauss syndrome.

[Q: 1326] OnExamination - Respiratory

An 18-year-old female with alpha1-antitrypsin deficiency attends clinic 12 weeks pregnant.

She wants to know if her child would be affected.

What is the mode of inheritance of this disease?

- 1- Autosomal dominant
- 2- X-linked recessive
- 3- Autosomal recessive
- 4- Polygenic
- 5- X-linked dominant

Answer & Comments

Answer: 3- Autosomal recessive

Alpha-1-antitrypsin deficiency is inherited in an autosomal recessive pattern, which causes emphysema and cirrhosis and has a prevalence of 1 in 2500.

[Q: 1327] OnExamination - Respiratory

Which ONE of the following is correct regarding severe bullous emphysema:

- 1- Helium dilution is more accurate than body plethysmography in measuring residual volume.
- 2- Hypoxaemia at rest will improve with exercise.
- 3- Pulmonary compliance is reduced.
- 4- Reduced elastic recoil opposes airway collapse in expiration.
- 5- The carbon monoxide transfer factor is reduced.

Answer & Comments

Answer: 5- The carbon monoxide transfer factor is reduced.

" Whole body plethysmography also measures trapped gas ie intrathoracic gas (including within bullae and other poorly ventilated areas) which barely communicates with the airway. Standard gas-dilution

measures gas that communicates with the airway. Mixing in helium dilution is more difficult in airways obstruction requiring multibreath methods lasting 5 minutes rather than single breath test.

" Exertion will exacerbate breathlessness and hypoxia.

" The characteristic changes of severe emphysema are increase in static compliance and reduction in lung recoil pressure.

" Loss of lung recoil causes a reduction of alveolar pressure (elastic recoil pressure of lung + pleural pressure) leading to collapse of peripheral airways on expiration. Emphysematous patients purse their lips in expiration to increase airway pressure to prevent this collapse.

" CO transfer factor is reduced.

[Q: 1328] OnExamination - Respiratory

A 56-year-old man presents with night time sweats, nocturia, poor concentration and day time somnolence.

To which of the following conditions does this diagnosis predispose?

- 1- Hypoglycaemia
- 2- Hypotension
- 3- Insulin sensitivity
- 4- Osteoporosis
- 5- Stroke

Answer & Comments

Answer: 5- Stroke

This history is typical of sleep apnoea. Sleep apnoea is an independent risk factor for stroke (and death from all causes), and is associated with hypertension, IGT, and insulin resistance.

[Q: 1329] OnExamination -
Respiratory

A 41-year-old man with a history of nasal congestion, breathlessness, cough and wheeze presents with a left foot drop.

Which of the following is the most likely diagnosis?

- 1- Diabetes mellitus
- 2- Wegeners Granulomatosis
- 3- Churg Strauss Syndrome
- 4- Pulmonary eosinophilia
- 5- Polyarteritis Nodosa

Answer & Comments

Answer: 3- Churg Strauss Syndrome

Churg Strauss syndrome is an eosinophilic vasculitis involving small and medium sized arteries and veins. It has three progressive phases; the first prodromal phase is of asthma and rhinitis, the second of tissue and peripheral blood eosinophilia and the final phase of systemic vasculitis. Asthma may precede the onset of vasculitis by many years although all three phases can occur together. Peripheral nervous system involvement usually takes the form of a mononeuritis multiplex or a mixed sensory and motor polyneuritis.

[Q: 1330] OnExamination -
Respiratory

Which of the following is NOT employed in the laboratory diagnosis of respiratory viral infections?

- 1- Immunofluorescence
- 2- Tissue culture
- 3- Haemagglutination
- 4- ELISA
- 5- Single radial haemolysis (SRH)

Answer & Comments

Answer: 5- Single radial haemolysis (SRH)

Rapid antigen-detection kits utilizing direct immunofluorescence are used to demonstrate RSV, influenza, parainfluenza and adenovirus in respiratory secretions. Respiratory viruses can be grown in various cell lines e.g. HeLa cells or fibroblasts. Influenza is a haemagglutinating virus as red cells stick to the infected cells after addition to the culture. ELISA is used to look for antibodies in acute and convalescent sera. The SRH test is used to screen for rubella antibodies in pregnant women.

[Q: 1331] OnExamination -
Respiratory

An 18-year-old attending the A+E department is noted to have central cyanosis. She is perfectly well but was told to go to A+E by her friends who said she looked blue.

What is the most likely cause?

- 1- Carbon Monoxide Poisoning
- 2- Lead Poisoning
- 3- Drinking water contaminated with nitrates
- 4- Anorexia Nervosa
- 5- Severe Anaemia

Answer & Comments

Answer: 3- Drinking water contaminated with nitrates

This is typical of methaemoglobinaemia which may be caused by nitrates.

[Q: 1332] OnExamination -
Respiratory

A 7 month old boy is presented to a doctor by his parents with symptoms of recurrent upper respiratory tract infections. No other members of the family suffer from any similar

infections. Physical examination showed mild facial hypoplasia.

Biochemistry investigations revealed hypocalcaemia. Microbiological investigations were normal and immunoglobulins were within normal limits.

The infants immune function would show the following deficiency:

- 1- Complement Deficiency
- 2- B cell number and function
- 3- T cell number and function
- 4- Plasma Cell
- 5- Macrophage number and function

Answer & Comments

Answer: 3- T cell number and function

This child suffers from DiGeorges syndrome. Patients with DiGeorges Syndrome often have near normal levels of immunoglobulins but with significant decreases in T cell numbers and relative increase in the percentage of B cells.

[Q: 1333] OnExamination - Respiratory

A 63 year-old diabetic presents with a pyrexia, productive cough and shortness of breath for 5 days. She has RLL consolidation and a small unilateral pleural effusion on CXR.

Which is a marker of poor prognosis?

- 1- Temp >38°C
- 2- WCC > 15
- 3- Her age
- 4- Her CXR signs
- 5- Her diabetes

Answer & Comments

Answer: 5- Her diabetes

Indicators of poor prognosis in pneumonia include: age >65, co-existing morbidity including diabetes mellitus, chronic renal failure, stroke, coronary artery disease, respiratory rate >30 and mental impairment.

Biochemical/haematological markers include white count < 4 or > 30, hypoxia needing CPAP or FiO₂ > 60%, positive blood culture and blood urea > 7.

[Q: 1334] OnExamination - Respiratory

A 65-year-old woman presented with increasing fatigue, dyspnoea and a dry cough. Her chest X-ray shows an area of dense pneumonia-like consolidation in the right lower lobe. A course of antibiotics did not improve her symptoms or chest X-ray. Bronchioalveolar lavage (BAL) retrieved 'atypical' cells.

What is the most likely diagnosis?

- 1- Bronchioloalveolar cell carcinoma
- 2- Mycoplasma pneumonia
- 3- Pulmonary alveolar proteinosis
- 4- Pulmonary embolism with infarction
- 5- Sarcoidosis

Answer & Comments

Answer: 1- Bronchioloalveolar cell carcinoma

"Bronchoalveolar carcinoma accounts for between 1-20% of pulmonary neoplasms. The population most affected is middle-aged, with no predilection for either sex. Interestingly, there is an increased incidence in patients with scleroderma or other diseases causing localized parenchymal scarring or diffuse interstitial fibrosis. Diffuse bilateral involvement in bronchoalveolar cell carcinoma occurs late in the disease and is usually spread by the bronchial tree. Manifestations include both local and diffuse forms. The local form may grow very slowly changing little for several years. The diffuse form simulates an

airspace filling disease with air bronchograms and air broncholograms. A pleural effusion develops in 8-10% of cases."

[Q: 1335] OnExamination - Respiratory

Which of the following statements is true of the pulmonary function test's vital capacity (VC)?

- 1- Vital capacity cannot be measured from spirometry alone
- 2- Vital capacity is increased in emphysema and reduced in interstitial fibrosis
- 3- Vital capacity is the maximal amount of air which can be exhaled after maximal inspiration
- 4- Vital capacity is the sum of tidal volume (VT) and inspiratory capacity (IC)
- 5- Vital capacity, when reduced, is a specific indication of restrictive lung disease

Answer & Comments

Answer: 3- Vital capacity is the maximal amount of air which can be exhaled after maximal inspiration

[Q: 1336] OnExamination - Respiratory

A 61-year-old, heavy smoker, with a BMI of 37, presents with impotence, nocturia and depression. He is hypoxic at rest on air and has ankle oedema.

Which is the most appropriate investigation to determine the aetiology?

- 1- Arterial blood gas
- 2- Chest x-ray
- 3- Ventilation-perfusion scan
- 4- Thyroid function test
- 5- Sleep study

Answer & Comments

Answer: 5- Sleep study

The clinical scenario describes cor pulmonale secondary to diurnal respiratory failure. This occurs in patients with severe obstructive sleep apnoea (OSA). Most patients who develop this complication have lower airway obstruction (from smoking), gross obesity or respiratory muscle weakness. Hypercapnia out of proportion to the degree of lung disease should suggest OSA as a possibility.

[Q: 1337] OnExamination - Respiratory

Most of the cells that fill the alveoli in desquamative interstitial pneumonitis (DIP) are which of the following?

- 1- Eosinophils
- 2- Lymphocytes
- 3- Macrophages
- 4- Neutrophils
- 5- Plasma cells

Answer & Comments

Answer: 3- Macrophages

[Q: 1338] OnExamination - Respiratory

Which of the following statements concerning industrial lung disorders is correct?

- 1- pneumoconiosis can be diagnosed in the absence of chest X-ray abnormalities
- 2- occupational asthma occurs more frequently in atopic persons
- 3- silo fillers disease is caused by allergy to grain
- 4- widespread crepitations are typically heard in extrinsic allergic alveolitis
- 5- symptoms occur within minutes if exposure to mouldy hay in Farmer's lung

Answer & Comments

Answer: 2- occupational asthma occurs more frequently in atopic persons

a-Pneumoconiosis is an X-Ray diagnosis. It is due to deposition of coal dust in parenchyma and reaction to its presence. The types - simple / complicated - are diagnosed on XRay appearance

b-It also occurs more frequently in smokers.

c-Silo fillers' disease is pulmonary oedema caused by inhalation of oxides of nitrogen generated by fresh silage.

d - examination in EAA usually reveals inspiratory crepitations which tend to be basal rather than widespread, sometimes squeaks, but wheeze is not typical.

e-Symptoms usually occur within hours.

[Q: 1339] OnExamination - Respiratory

A 20-year-old male student is assessed for shortness of breath that occurs whilst running. He has no other symptoms and does not smoke. Examination, full blood count, and chest X-ray are normal.

Which of the following is most likely to be helpful in confirming the suspected diagnosis?

- 1- Arterial blood gas studies before and after exercise
- 2- Determination of lung volumes and diffusing capacity
- 3- Measurement of venous blood lactate before and after exercise
- 4- Spirometry before and after administration of bronchodilators
- 5- Spirometry before and after exercise

Answer & Comments

Answer: 5- Spirometry before and after exercise

The most likely diagnosis is exercise induced asthma and this would be best diagnosed with spirometry before and after exercise where a typical obstructive pattern may be displayed following exercise. No abnormalities may be displayed following bronchodilator therapy if true exercise induced asthma. Similarly lung volumes and diffusion capacity are likely to be unaffected. Blood gas analysis would be relatively unhelpful in this scenario as little change in partial pressures would be expected. This patient does not have a glycogen storage disease where weakness rather than shortness of breath is more typical. Hence lactate measurements are unnecessary.

[Q: 1340] OnExamination - Respiratory

Which one of the following statements is true of chronic obstructive pulmonary disease?

- 1- patients show at least a 15 per cent improvement in the FEV₁ after nebulised bronchodilator
- 2- inhaled corticosteroid usage does not improve long-term prognosis
- 3- breathlessness is uncommon until the FEV₁ falls to approximately 50 per cent of predicted
- 4- emphysema is associated with increased transfer factor
- 5- in advanced cases there is reduced pulmonary vascular resistance

Answer & Comments

Answer: 2- inhaled corticosteroid usage does not improve long-term prognosis

A. This level of improvement would mean the presence of asthma.

B. High dose inhaled steroids have been shown (ISOLDE) to improve quality of life and reduce hospitalisation rates by reducing the number of exacerbations, but it does not slow

the rate of decline of FEV₁ (hence does not affect prognosis).

C. Breathless is common but subjective. Mild COPD (60 - 79% predicted FEV₁) are often unknown to their GP. Those with moderate COPD (40 - 59% predicted) are seen intermittently seen by GP, whilst those with severe disease (< 40% predicted) have frequent hospital and GP visits.

D. It is asthma which is associated with normal or increased transfer factor. COPD is associated with decreased transfer factor.

E. COPD is associated with secondary pulmonary hypertension.

[Q: 1341] OnExamination - Respiratory

A 45-year-old man presents with a three month history of wheezing and dyspnoea whilst at work. His symptoms improve significantly when at home and at weekends.

What is the likely causative agent?

- 1- Asbestos
- 2- Cotton dust
- 3- Isocyanates
- 4- Silica
- 5- Simple coal workers lung

Answer & Comments

Answer: 3- Isocyanates

This patient presents with typical symptoms of occupational asthma and the most likely causative substance is isocyanate which is used in the manufacture of foams/plastics. There are an estimated 1500 to 3000 cases of occupational asthma reported each year. Other implicated substances include Flour dust, wood dust, latex, solder and glues.

[Q: 1342] OnExamination - Respiratory

A patient's arterial blood gas analysis gives the following results:

pO₂ 10 kPa (75mmHg)

pCO₂ 7 kPa (52 mmHg)

pH 7.47

Bicarbonate 37 mmol/L

Which of the following is the most likely cause?

- 1- Chronic hyperventilation Syndrome
- 2- Acute exacerbation of chronic obstructive pulmonary disease
- 3- Pyloric obstruction
- 4- Pulmonary embolism
- 5- Diabetic coma

Answer & Comments

Answer: 3- Pyloric obstruction

These results demonstrate a metabolic alkalosis and there is respiratory compensation with an elevation of pCO₂ in an effort to compensate for the alkalosis. Consequently, pO₂ is slightly low. The most probable cause is pyloric stenosis.

[Q: 1343] OnExamination - Respiratory

The parents of a child with cystic fibrosis consult you wishing to know what is the risk of their next child being a carrier of the condition.

Which ONE of the following percentages is the correct risk?

- 1- 0%
- 2- 25%
- 3- 50%
- 4- 75%
- 5- 100%

Answer & Comments

Answer: 3- 50%

As both parents are carriers for the CF gene then the chances of another child being affected (homozygote) is 1 in 4 (25%). The chances of their child being free from the CF gene is also 1 in 4 (25%) and the chances of a child being a carrier (heterozygote) is 1 in 2 (50%).

[Q: 1344] OnExamination - Respiratory

An otherwise healthy 78-year-old female presents complaining of a 3-day history of tiredness and breathlessness. Her pulse oximetry shows oxygen saturation of 90%. Arterial blood gas analysis performed on air shows

pH 7.3 (7.35-7.45)

pO₂ 7.8 kPa (9-13)

pCO₂ 7.5 kPa (3.5-5.5)

Bicarbonate 30 mmol/l (22-28)

What is the most likely cause?

- 1- Bronchial asthma
- 2- Left ventricular failure
- 3- Lobar pneumonia
- 4- Neuromuscular weakness
- 5- Pulmonary embolism

Answer & Comments

Answer: 4- Neuromuscular weakness

This patient has type 2 respiratory failure as evidence by hypoxia PaO₂ of <8.0kPa and hypercapnia PaCO₂ >6.0kPa. This occurs when alveolar ventilation is insufficient to excrete the amount of CO₂ produced by metabolism. This is due to reduced ventilatory effort, failure to overcome increased resistance to ventilation, failure to compensate for an increase in CO₂ production or a combination of these factors. The commonest cause is

chronic obstructive airway disease, other causes include respiratory muscle weakness eg Guillaine Barre syndrome, chest wall deformity respiratory centre weakness.

The other causes listed here produce type 1 respiratory failure with a mismatch between ventilation and perfusion.

[Q: 1345] OnExamination - Respiratory

A 45-year-old seaman presents with cough and fever. A

CXR demonstrates a cavitating lung lesion.

Which of the following is the most likely cause:

- 1- Histoplasmosis
- 2- Syphilis
- 3- Sarcoidosis
- 4- Amoebiasis
- 5- Brucellosis

Answer & Comments

Answer: 1- Histoplasmosis

Histoplasmosis normally evolves slowly over as long as 20 years but may follow a more rapid course in the immunocompromised (Seamen may be more prone to sexually transmitted diseases such as HIV). Amoebic abscesses can develop in the right lower lobe following transdiaphragmatic spread from amoebic liver abscess (tender hepatomegaly, malaise, spiking temperature). Amoebiasis is also a fresh water pathogen.

[Q: 1346] OnExamination - Respiratory

A 43-year-old asthmatic develops worsening breathlessness and his full blood count has revealed an eosinophilia.

A diagnosis of allergic bronchopulmonary aspergillosis is suspected.

Which of the following statements is true with regard to this diagnosis?

- 1- The immediate skin test to an extract of aspergillus fumigatus is negative
- 2- Circulating IgG precipitins to aspergillus fumigatus are positive
- 3- The CO transfer factor is unaffected
- 4- Recurrent haemoptysis is a characteristic feature
- 5- Pleural effusion is a complication

Answer & Comments

Answer: 2- Circulating IgG precipitins to aspergillus fumigatus are positive

Immediate (type I) reactions occur in virtually all patients with ABPA following intradermal injections of A fumigatus extracts, with only 16% developing delayed (type III) reactions. Precipitating IgG antibodies are present in 70% of patients. Transfer factor may be affected in the later fibrotic stage of the disease. Haemoptysis is symptom of aspergilloma and bronchiectasis, but is not characteristic of ABPA.

[Q: 1347] OnExamination - Respiratory

In the normal lung which of the following is correct?

- 1- There is an intrapleural pressure of 30 cmH₂O (3kPa) at the end of normal expiration.
- 2- There is a resting pulmonary blood flow of 10L/min.
- 3- The V:Q ratio is greater in apical than basal segments of the lung when upright and at rest.
- 4- The majority of airway resistance is generated by small airways.
- 5- Cartilage is present in all respiratory bronchioles.

Answer & Comments

Answer: 3- The V:Q ratio is greater in apical than basal segments of the lung when upright and at rest.

Because of surfactant, the pressure difference across the pleura required to inflate the lungs, is usually no more than about 4cmH₂O. Resting pulmonary blood flow in an adult is around 5L/min. Gas rises, so the V:Q ratio is higher in the apical than the basal segments. While a single small airway provides more resistance than a single large airway, resistance to air flow depends on the number of parallel pathways present. For this reason, the large and particularly the medium-sized airways actually provide greater resistance to flow than do the more numerous small airways. Cartilage disappears in the terminal bronchioles.

[Q: 1348] OnExamination - Respiratory

A 47-year-old woman presenting with breathlessness has arterial blood gases taken which give the following results: pO₂ 8.7 kPa (65mmHg), pCO₂ 4.4 kPa (33mmHg), pH 7.46, { HCO₃⁻ } 24.

Which of the following is the most likely diagnosis?

- 1- Hyperventilation syndrome
- 2- Acute severe asthma
- 3- Emphysema
- 4- Kyphoscoliosis
- 5- Opiate overdose

Answer & Comments

Answer: 2- Acute severe asthma

The patient has an acute respiratory alkalosis with associated hypoxia. This is consistent with an acute asthmatic attack. A normal or rising CO₂ is an ominous sign indicative of a life threatening attack and the need to

consider ventilatory support. Patients with hyperventilation syndrome do show a respiratory alkalosis but this is not associated with hypoxia.

[Q: 1349] OnExamination - Respiratory

Which of the following statements is true of the diffusion capacity of carbon monoxide?

- 1- Is a specific measure of lung perfusion.
- 2- Depends on the thickness of the alveolar wall.
- 3- Is not affected by changes in the surface area available for gas exchange.
- 4- Is increased in cigarette smokers.
- 5- Is increased in emphysema.

Answer & Comments

Answer: 2- Depends on the thickness of the alveolar wall.

By Fick's law, the volume of gas diffusing across a membrane equals $A/T \times D \times$ difference in partial pressure. In life it is impossible to measure accurately the area (A) or the thickness (T), and these are subsumed into a single constant, the diffusion capacity for carbon monoxide. $DL = \text{volume of transferred carbon dioxide} / \text{partial pressure difference between the alveoli and the capillary blood}$. Since the capillary blood normally does not contain carbon dioxide this term disappears. Diffusion will be increased in healthy compared with unhealthy lungs, where the thickness is likely to increase and the surface area available for gas exchange to decrease. V/Q imbalances can indirectly interfere with carbon dioxide diffusion capacity by decreasing the available area of lung for gas exchange, but it is not a specific measure of lung perfusion.

[Q: 1350] OnExamination - Respiratory

What is the most likely cause of upper lobe fibrosis on Chest X-ray?

- 1- Ankylosing spondylitis
- 2- Cryptogenic fibrosing alveolitis
- 3- Rheumatoid arthritis
- 4- Scleroderma
- 5- Systemic lupus erythematosus

Answer & Comments

Answer: 1- Ankylosing spondylitis

Cryptogenic fibrosing alveolitis (which may be associated with connective tissue disorders) affects lower lobes and is associated with clubbing. Extrinsic allergic alveolitis is not associated with clubbing and affects middle/upper zones.

[Q: 1351] OnExamination - Respiratory

A new publication describes a new test for cystic fibrosis. You want to know what proportion of patients with cystic fibrosis who would be correctly identified by this new test.

Which one of the following values would identify this?

- 1- accuracy
- 2- negative predictive value
- 3- positive predictive value
- 4- sensitivity
- 5- specificity

Answer & Comments

Answer: 4- sensitivity

The proportion of patients with the disease who would be identified by the new test is the sensitivity. This refers to the proportion with the disease who truly have cystic fibrosis and are identified as such by the test. Positive

predictive value refers to the percent of people having a positive test who actually have the disease interpreted in conjunction to the prevalence of the disease (True positives/True positives+False positives).

[Q: 1352] OnExamination - Respiratory

A 80-year-old coal miner who stopped working 16 years previously presents with deteriorating dyspnoea.

Investigations show:

FEV₁ 1.4L (predicted 2.5)

FVC 2.8L (predicted 3.0)

What is the most likely diagnosis?

- 1- Chronic obstructive pulmonary disease
- 2- Cryptogenic fibrosing alveolitis
- 3- Extrinsic allergic alveolitis
- 4- Silicosis
- 5- Simple pneumoconiosis

Answer & Comments

Answer: 1- Chronic obstructive pulmonary disease

Both this man's FEV₁ and FVC are reduced. The ratio of FEV₁/FVC is also reduced at 50%. This indicates airways obstruction. Chronic obstructive pulmonary disease (COPD) is the only condition above that results in airways obstruction. Although no smoking history is given this may be expected and his occupation are risk factors for the development of COPD.

[Q: 1353] OnExamination - Respiratory

A 72-year-old lifelong smoker presents with progressive dyspnoea on exertion. He has a chronic, nonproductive cough. On examination he is thin, breathing with pursed lips, respiratory rate 25/min, with mild wheezing on chest auscultation.

Investigations show:

FEV₁ 0.8 L FVC 1.6 L

pH 7.35 paCO₂ 45 mmHg

paO₂ 55 mmHg

What is the predominant mechanism of the airflow limitation in this gentleman?

- 1- Bronchospasm
- 2- Foreign body obstruction
- 3- Increased airways resistance
- 4- Loss of elastic recoil
- 5- Mucus plugging in the small airways

Answer & Comments

Answer: 4- Loss of elastic recoil

This patient has typical features of COAD with a predominant emphysematous element. The pathology is centrilobular or panacinar with loss of elastic tissue.

[Q: 1354] OnExamination - Respiratory

A patient with Rheumatoid arthritis complains of progressive breathlessness.

Which of the following is the most likely cause?

- 1- Pulmonary Eosinophilia
- 2- Asthma
- 3- Pulmonary nodules
- 4- Fibrosing Alveolitis
- 5- Pulmonary Embolus

Answer & Comments

Answer: 4- Fibrosing Alveolitis

Fibrosing alveolitis associated with rheumatoid arthritis is indistinguishable from cryptogenic fibrosing alveolitis. It presents with progressive breathlessness and cough. Signs include finger clubbing, cyanosis and bilateral end inspiratory crackles. Other

pulmonary complications of Rheumatoid arthritis include pleural effusions, empyema, cryptogenic organising pneumonia, bronchiectasis and pulmonary nodules. The latter are usually asymptomatic but may cavitate resulting in haemoptysis and when occurring with coal workers pneumoconiosis (Caplans Syndrome) are associated with breathlessness.

[Q: 1355] OnExamination - Respiratory

A 20-year-old student is found in her bedroom by friends drowsy, confused and sweating. She is unable to give a clear history.

On examination she has a fever of 38.3°C, pulse 110 bpm, BP 110/60 and she appears short of breath with a respiratory rate of 30. Her chest sounded clear to auscultation.

Arterial blood gas result taken on 15 L/min oxygen shows:

pH 7.29 (7.35-7.45)

paO₂ 16 kPa (11-14)

paCO₂ 2.1 kPa (4.5-6)

Which of the following is the most likely diagnosis?

- 1- Aspirin overdose
- 2- Cocaine use
- 3- Legionella pneumonia
- 4- Meningococcal septicaemia
- 5- Severe asthma

Answer & Comments

Answer: 1- Aspirin overdose

There are a number of clues here that point to aspirin toxicity. Fever, sweating, tachypnoea and acidosis. The presence of confusion suggests a severe overdose.

In severe asthma and Legionella pneumonia hypoxia would be expected. Meningococcal septicaemia does not explain the tachypnoea.

[Q: 1356] OnExamination - Respiratory

A 22-year-old lady recently returned from a holiday in Malta was admitted with a 3 day history of fever, generalised lymphadenopathy and a macular rash over the trunk and legs.

Which of the following is the most likely diagnosis.

- 1- Sarcoidosis
- 2- Tuberculosis
- 3- Familial Mediterranean Fever
- 4- Infectious Mononucleosis
- 5- Actinomycosis

Answer & Comments

Answer: 4- Infectious Mononucleosis

Infectious Mononucleosis occurs most commonly in adolescents and young adults. Clinical features occur after a 2-5 week incubation period and include fever, malaise, pharyngitis, and lymphadenopathy. Rashes occur more commonly in patients that have received penicillin or ampicillin.

[Q: 1357] OnExamination - Respiratory

A 35-year-old man presents after 3 months of chronic cough with purulent sputum and shortness of breath on exertion. He gives a history of at least two sinus or bronchial infections per year requiring treatment with antibiotics. He also says he and his wife have been unable to have children. He smokes 15 cigarettes per day. Examination is normal except for some wheezing and an area of focal crackles at the left lung base. Chest X-ray shows patchy infiltrates at both bases.

Investigations revealed

FEV₁ 2.0 L

FVC 2.7 L

pH 7.38

paCO₂ 40 mmHg

paO₂ 82 mmHg

What is the most likely diagnosis?

- 1- alpha-1-Antitrypsin (Antiprotease) deficiency
- 2- Asthma
- 3- Cystic fibrosis
- 4- Hypogammaglobulinemia
- 5- Immotile cilia syndrome

Answer & Comments

Answer: 5- Immotile cilia syndrome

Immotile Cilia Syndrome, also known as Primary Ciliary Dyskinesia and includes Kartegener's Syndrome, is an inherited condition where the cilia lining the airways fail to function or function ineffectively. A defect in the dynein molecule causes the cilia to either totally cease to function or function ineffectively. Kartegener's Syndrome is a subset of patients that account for about half of all people with Immotile Cilia Syndrome. Other associated conditions of Immotile Cilia Syndrome are male infertility, congenital heart defects, deafness, and hydrocephalus. Cystic fibrosis is unlikely to present at this age. Infertility is not typically associated with hypogammaglobulinaemia.

[Q: 1358] OnExamination - Respiratory

A 21-year-old gentleman with cystic fibrosis presents with infertility.

What is the most likely cause for this?

- 1- Chronic prostatic insufficiency
- 2- Failure of development of the vas deferens
- 3- Increasing alkalinisation of semen
- 4- Primary failure of testosterone production
- 5- Production of anti-sperm antibodies

Answer & Comments

Answer: 2- Failure of development of the vas deferens

Infertility occurs in 98% of adult men secondary to maldevelopment of the vas deferens or to other forms of obstructive azoospermia. In women, fertility is decreased secondary to viscid cervical secretions.

[Q: 1359] OnExamination - Respiratory

In a study of a new drug for asthma, a researcher wishes to compare average serum drug concentrations in volunteers, four hours after taking the drug; a. in the fasting state then b. after a meal.

Which of the following would be the most appropriate statistical test to use?

- 1- chi-squared test
- 2- Pearson's correlation coefficient
- 3- Student's paired t-test
- 4- Student's unpaired t-test
- 5- Wilcoxon test

Answer & Comments

Answer: 3- Student's paired t-test

In this scenario we are dealing with use of the drug in the same volunteers with the intervention being the effect of feeding on drug concentrations. Thus you'll be comparing means in the same subjects and the paired t-test would be the most appropriate test.

[Q: 1360] OnExamination - Respiratory

A 60-year-old woman presents with deteriorating dyspnoea and cough productive of a purulent sputum. She has a two year history of recurrent chest infections and is a smoker of 5 cigarettes daily.

On examination, she appeared breathless with a pulse of 100 bpm and a temperature was 39°C.

Investigations revealed:

Haemoglobin 19.5 g/dL (13.0-18.0)??

White cell count $15.7 \times 10^9/L$ (4-11)

Platelet count $350 \times 10^9/L$ (150-400)?

paO₂ 6.8 kPa (11.3-12.6)

Carboxyhaemoglobin 15.5% (3-15)

Red cell mass 147% (75-125)

What is the most likely explanation for these findings?

- 1- Chronic obstructive airways disease
- 2- Ectopic erythropoietin production
- 3- ?Myelofibrosis???
- 4- Primary polycythaemia
- 5- Pseudo-polycythaemia

Answer & Comments

Answer: 1- Chronic obstructive airways disease

This patient has polycythaemia which is likely to be secondary to her hypoxia. The cause of the hypoxia is most likely to be due to chronic obstructive pulmonary disease as a result of his heavy smoking history. His history of increasing breathlessness, cough and sputum production and recurrent chest infections is consistent with this diagnosis. The treatment is for her to stop smoking and long term oxygen therapy (LTOT) (i.e. oxygen > 15 hours /day).

The indications for LTOT are: paO₂ < 7.3 kPa (55 mmHg) or paO₂ < 8.0 kPa (60 mmHg) with evidence of pulmonary hypertension, peripheral oedema or polycythaemia.

[Q: 1361] OnExamination - Respiratory

Which of the following would be the least

likely finding in a patient with sarcoidosis?

- 1- Hepatic granulomas
- 2- Restrictive pulmonary function tests
- 3- Skin lesions
- 4- Uveitis
- 5- X bodies on bronchoalveolar lavage (BAL) fluid

Answer & Comments

Answer: 5- X bodies on bronchoalveolar lavage (BAL) fluid

Sarcoidosis is associated uveitis, arthritis, pulmonary fibrosis, lymphadenopathy and skin changes - lupus pernio/erythema nodosum. It is characterised histologically by the presence of non-caseating granulomas which may occur anywhere. These granulomas have the capacity to produce 1,25 vitamin D explaining the associated hypercalcaemia. Pentamellar X bodies (Birbeck granules) found on BAL are considered diagnostic of Pulmonary Histiocytosis X and so would not be expected with sarcoidosis.

[Q: 1362] OnExamination - Respiratory

Recognised associations.

Which of the following is correct?

- 1- pneumoconiosis and clubbing
- 2- lung carcinoids and pleural effusion
- 3- pulmonary embolus and left bundle branch block
- 4- pulmonary fibrosis and hypercapnia
- 5- bronchopulmonary aspergillosis and wheezing

Answer & Comments

Answer: 5- bronchopulmonary aspergillosis and wheezing

Pulmonary fibrosis associated with type 1 respiratory failure, which is associated with ventilation/perfusion mismatch. Allergic bronchopulmonary aspergillosis caused by *Aspergillus fumigatus*, which can present with asthma and eosinophilia.

[Q: 1363] OnExamination - Respiratory

A 16-year-old girl presents with a 2 day history of deteriorating breathlessness and dyspnoea. Blood gas analysis shows a pH of 7.25, a $p\text{CO}_2$ of 7.0kPa, a $p\text{O}_2$ of 8.5kPa, and a base excess of -4.

Which of the following interpretations is correct?

- 1- Results are consistent with bronchopulmonary dysplasia.
- 2- Blood gases suggest type 1 respiratory failure.
- 3- Immediate intubation is required.
- 4- Results are consistent with late severe asthma.
- 5- Bicarbonate may be necessary to correct the acidosis.

Answer & Comments

Answer: 4- Results are consistent with late severe asthma.

In interpreting blood gas results, the following sequence may be useful:

" Inspect the pH: Is it low, normal or high?

" Inspect the CO_2 : Is it low, normal or high?

" Inspect the PO_2 : Is it low, normal or high?

If the pH is low then an acidosis is present, and inspecting the CO_2 will enable you to determine whether this is due to respiratory or metabolic causes. Inspecting the PO_2 will

tell you whether the patient is hypoxic or not. In this case, the pH is reduced, and the CO_2 is high, with a base deficit of only -4, insufficient to explain the acidosis from metabolic causes. This is, therefore, a respiratory acidosis, and the PO_2 is also low suggesting type 2 respiratory failure. Possible causes would include severe pneumonia, end stage asthma or neurogenic causes such as guillain-Barre. In asthma, the initial stages show a low CO_2 , with this climbing only to accompany failing respiration. The results would therefore be consistent with late severe asthma. In bronchopulmonary dysplasia, there is usually long-term CO_2 retention with compensatory increase in bicarbonate leading to a positive base excess and normal pH. Bicarbonate is usually only considered if the base deficit exceeds about -8.

[Q: 1364] OnExamination - Respiratory

A 20-year-old female with cystic fibrosis presents in early pregnancy wanting advice.

Genetic analysis reveals that her partner is a carrier of the cystic fibrosis gene.

What is the chance of her child having cystic fibrosis?

- 1- 10
- 2- 25
- 3- 50
- 4- 75
- 5- 100

Answer & Comments

Answer: 3- 50

The patient is homozygous for CF (CF/CF) and the father is heterozygous for CF (CF/N). Thus there is a 50% chance that her child will be homozygous for CF and a 50% chance that the child will be a carrier.

[Q: 1365] OnExamination -
Respiratory

Which of the following is a recognised treatment for complications of cystic fibrosis?

- 1- DNAase to assist in reinflating collapsed lung segments.
- 2- Rectal pull-through and anastomosis for rectal prolapse.
- 3- Pancreatic transplant for diabetes mellitus.
- 4- Nebulised tobramycin for pseudomonas colonisation of the lower respiratory tract.
- 5- Hypotonic saline drinks for hypernatraemic dehydration.

Answer & Comments

Answer: 4- Nebulised tobramycin for pseudomonas colonisation of the lower respiratory tract.

Human recombinant DNAase given as a single daily aerosol seems to improve pulmonary function, decrease the frequency of chest exacerbations, and promotes a sense of well-being in patients with mild to moderate disease with purulent secretions. This may be because, in the inflamed airway, the nuclei from dead cells accounts for much of the viscosity of secretions. Rectal prolapse is usually idiopathic, occurring between 1 and 5 years. Intestinal parasites, malnutrition, acute diarrhoea, ulcerative colitis, pertussis, Ehler's Danlos Syndrome, meningocele, cystic fibrosis, and chronic constipation can also predispose to it. Following defecation the prolapse usually resolves spontaneously, or through manual reinsertion by the patient or parent. Nebulised tobramycin or gentamicin may be given when airway pathogens are resistant to oral antibiotics, or where infection is difficult to control at home. Hypernatraemic dehydration should be treated in the usual way.

[Q: 1366] OnExamination -
Respiratory

A 65-year-old man with known chronic obstructive pulmonary disease, treated with inhalers, was admitted with a six-week history of gradually increasing shortness of breath. He was apyrexial, mildly confused with a respiratory rate of 26 breaths per minute and there were no changes on the chest X-ray.

Investigations revealed:

paO₂ 7.8kPa (9-12.6)

paCO₂ 8.5kPa (4.7-6.0)

pH 7.3 (7.36-7.44)

What is the most appropriate immediate management?

- 1- High flow oxygen therapy
- 2- Intravenous aminophylline
- 3- Intravenous hydrocortisone
- 4- Intubation and mechanical ventilation.
- 5- Nebulized salbutamol and ipratropium bromide.

Answer & Comments

Answer: 5- Nebulized salbutamol and ipratropium bromide.

The patient normally uses inhalers and therefore is likely to respond to nebulised bronchodilators, which should be nebulised with air and not high flow oxygen. Corticosteroids have been shown to reduce length of stay in hospital, and are usually given in acute exacerbations of COPD. Non-invasive ventilation should be tried first in severe cases before progressing to mechanical ventilation if appropriate. IV aminophylline is recommended as a second to third line therapy of COPD with reversible airways.

[Q: 1367] OnExamination -
Respiratory

A 60-year-old man with ankylosing spondylitis

presents with cough, weight loss and tiredness. His CXR shows longstanding upper lobe fibrosis. Three sputum tests stain positive for Acid fast bacilli but are consistently negative for Mycobacterium tuberculosis on culture.

Which of the following is the most likely cause?

- 1- Mycobacterium avium intracellulare complex
- 2- Micropolyspora faeni
- 3- Allergic Bronchopulmonary Aspergillosis
- 4- Sarcoidosis
- 5- Tuberculosis

Answer & Comments

Answer: 1- Mycobacterium avium intracellulare complex

The presence of AFB yet absence of TB suggests an atypical AFB such as M. avium.

[Q: 1368] OnExamination - Respiratory

A 56-year-old female presents with a six month history of deteriorating non productive cough and exertional dyspnoea. On examination she is noted to be cyanosed, has clubbing of the fingers and there are bilateral basal crackles. A chest X-ray reveals bilateral basal shadowing and pulmonary investigations show:

paO₂ (on air) 8.5 kPa (11.5-12.5)

FEV₁/FVC ratio 85%

Which one of the following investigations is most likely to establish the diagnosis?

- 1- Bronchoalveolar lavage
- 2- Chest CT scan
- 3- Diffusion Capacity studies
- 4- Echocardiography
- 5- Serum ACE level

Answer & Comments

Answer: 2- Chest CT scan

This patient has restrictive lung disease, most likely Cryptogenic fibrosing alveolitis, the cardinal features being breathlessness and cyanosis, clubbing occurs in two-thirds of cases. She is hypoxic on air, has a restrictive ventilatory defect, and a high resolution CT scan of the chest will show typical changes.

[Q: 1369] OnExamination - Respiratory

A 50-year-old male is taken to the General Practitioner by his long suffering wife. His snoring (which has been steadily increasing in loudness over the past 18 months) is troublesome at home. She says that he makes noises and moves around whilst asleep.

He reports no problems with sleeping. He does admit to gaining 20 kg in weight over the past one year, and to falling asleep during the day.

A sleep study is performed.

Which of the following findings would be most compatible with this man's clinical presentation?

- 1- Fragmented sleep, cessations of airflow measured at the nose accompanied by an increase in oesophageal pressure swings and episodic oxygen desaturation.
- 2- Normal sleep quality, bradycardic episodes, oxygen desaturation but normal airflow.
- 3- Normal sleep quality but cessations of airflow measured at the nose with decreased abdominal wall motion during these flow cessations.
- 4- Progressive oxygen desaturation during the night and alternating periods of hyperventilation and hypoventilation.
- 5- Tachycardia, sleep fragmentation, episodes of hypoventilation with minimal oxygen desaturation.

Answer & Comments

Answer: 1- Fragmented sleep, cessations of airflow measured at the nose accompanied by an increase in oesophageal pressure swings and episodic oxygen desaturation.

[Q: 1370] OnExamination - Respiratory

65-year-old man came to the hospital for worsening breathlessness. He was a chronic smoker and previously diagnosed with lung cancer. Chest X-ray revealed elevation of left hemidiaphragm and left phrenic nerve palsy was suspected.

Which of the following findings on fluoroscopy of diaphragm will confirm the diagnosis?

- 1- No movement of the left hemidiaphragm
- 2- No movement of the right hemidiaphragm
- 3- Normal movement of both hemidiaphragms
- 4- Paradoxical movement of the left hemidiaphragm
- 5- Paradoxical movement of the right hemidiaphragm

Answer & Comments

Answer: 4- Paradoxical movement of the left hemidiaphragm

The diagnosis of phrenic nerve palsy is suspected when, on the chest radiograph, the diaphragmatic leaflet is elevated and is confirmed fluoroscopically by observing paradoxical diaphragmatic motion on sniff and cough. In patients with normal lungs, unilateral paralysis is usually asymptomatic and rarely requires treatment.

[Q: 1371] OnExamination - Respiratory

A 63-year-old woman presents a 5 day history of progressive shortness of breath. Her family brought her in because she was increasingly sleepy during the last 24 hours. She was

diagnosed with Chronic Obstructive Pulmonary Disease 3 years ago and has a FEV₁ less than 50% of predicted. She has an oxygen concentrator at home.

Examination revealed depressed consciousness and a respiratory rate of 24 with shallow breaths. There were decreased breath sounds with minimal air movement.

If an arterial blood gas on room air were to be performed, which of the following results would you expect?

- 1- pH 7.16 paCO₂ 70 paO₂ 50 HCO₃ 24
- 2- pH 7.24 paCO₂ 80 paO₂ 55 HCO₃ 30
- 3- pH 7.32 paCO₂ 60 paO₂ 70 HCO₃ 30
- 4- pH 7.41 paCO₂ 40 paO₂ 50 HCO₃ 24
- 5- pH 7.48 paCO₂ 30 paO₂ 85 HCO₃ 24

Answer & Comments

Answer: 2- pH 7.24 paCO₂ 80 paO₂ 55 HCO₃ 30

This patient's presentation suggests that she has developed acute carbon dioxide retention and would be expected to have a low pH, low pO₂, high pCO₂ and a high HCO₃ because she has long-standing COPD. Consequently the last three options really do not fit. The first option has a pretty much normal bicarbonate and this would be expected to be much higher in chronic COPD (as there would be metabolic alkalosis to compensate for the respiratory acidosis). Therefore this leaves the best fit as option B.

[Q: 1372] OnExamination - Respiratory

A 16-year-old girl presents with shortness of breath and insomnia prior to an examination.

Clinical examination is normal. CXR and PEFr are normal.

Which of the following investigations is most suggestive of asthma?

- 1- diurnal variation in PEFr > 20%

- 2- positive skin prick test to common allergens
- 3- past medical history of hayfever and eczema
- 4- increased total IgE
- 5- resolution of symptoms the day after the exam

Answer & Comments

Answer: 1- diurnal variation in PEFR > 20%

The history of atopy in this patient is consistent with a diagnosis of asthma. IgE being elevated really tells you little other than suggesting atopy and the skin prick would suggest allergy. The resolution of symptoms after the exam suggests anxiety. However, diurnal variation of PEFR >20% is one of the diagnostic criteria for asthma, and we feel this is the most appropriate answer in this case.

[Q: 1373] OnExamination - Respiratory

A 15-year-old boy presented with wheezing when playing football and nocturnal cough.

Which is the best test to confirm the underlying condition?

- 1- A trial of oral corticosteroids
- 2- A trial of inhaled corticosteroids
- 3- A trial of inhaled salbutamol
- 4- Serial peak expiratory flow rate measurements
- 5- Spirometry alone

Answer & Comments

Answer: 4- Serial peak expiratory flow rate measurements

Demonstration of variable obstruction of the airways provides good evidence for asthma, with its characteristic morning dips. Failure to respond to bronchodilator therapy does not exclude asthma as response may be small in children, and in adults with persistent or more

severe asthma. Those who fail to respond to inhaled bronchodilator require a steroid trial (either 4 weeks of high dose inhaled steroids or 2 weeks of oral Prednisolone).

[Q: 1374] OnExamination - Respiratory

A 60-year-old man with breathlessness, fever and headache is suspected of having Farmers Lung. A CXR shows diffuse nodular shadowing predominantly in the mid and lower zones.

What would be the most useful diagnostic test?

- 1- Blood Culture
- 2- Sputum Culture
- 3- Serum precipitating antibodies to Micropolyspora faeni
- 4- Serum Precipitating antibodies to Aspergillus clavatus
- 5- Serum Precipitating antibodies to Cryptostroma corticale

Answer & Comments

Answer: 3- Serum precipitating antibodies to Micropolyspora faeni

The diagnosis of Extrinsic Allergic Alveolitis is based on characteristic clinical, radiological and functional changes and confirmed by demonstration of precipitating antibodies (precipitins) in the patients serum to the causal antigen. In Farmers lung precipitins to M. faeni or Thermoactinomyces vulgaris are found in 75-100% of cases during an acute episode. A. clavatus is the antigen causing Malt Workers lung and C. corticale the antigen causing Maple Bark Strippers Lung.

[Q: 1375] OnExamination - Respiratory

A 55-year-old woman on treatment for long-standing rheumatoid arthritis has recently become dyspnoeic on mild exertion and

developed a dry cough. The oxygen saturation was found to be 87% on air. The chest x-ray showed a diffuse bilateral interstitial infiltrate. An extensive infection screen was negative and her symptoms were felt to be drug-induced.

Which drug is most likely to have caused this adverse effect?

- 1- azathioprine
- 2- cyclosporin
- 3- hydroxychloroquine
- 4- methotrexate
- 5- sulphasalazine

Answer & Comments

Answer: 4- methotrexate

Methotrexate is a well recognised cause of acute pneumonitis and interstitial lung disease. It is a rare complication of methotrexate therapy but is often fulminant and can be fatal.

[Q: 1376] OnExamination - Respiratory

A 52-year-old man enquired about the advisability of vaccination prior to a holiday abroad. He had been treated for asthma with long-term steroids and regularly required doses of Prednisolone in excess of 30mg daily to control acute exacerbations.

Which one of the following vaccinations would be contra-indicated in this man?

- 1- BCG
- 2- Diphtheria toxoid
- 3- H Influenzae B
- 4- Meningococcus
- 5- Tetanus toxoid

Answer & Comments

Answer: 1- BCG

Some individuals, particularly those that are immunosuppressed, are at risk if they are given live vaccines. Inactivated vaccines are generally not dangerous but may be ineffective. They are also at risk of severe manifestations to vaccines such as disseminated infection with BCG. Those patients who receive prednisolone 40mg/day for more than a week or who are on lower doses for more prolonged periods should be considered to be immunosuppressed. Asthma alone is not a contra-indication to vaccination even if patients are taking inhaled corticosteroids.

[Q: 1377] OnExamination - Respiratory

Which of the following statements regarding the sweat test is true?

- 1- Sweating is enhanced by application of atropine.
- 2- The filter paper is left on for a total of about 4 hours.
- 3- At least 25mg of sweat is necessary for a reliable result.
- 4- More than 60mmol/L of chloride in sweat is diagnostic of cystic fibrosis.
- 5- False/positive results may be encountered in children with nephrotic syndrome.

Answer & Comments

Answer: 4- More than 60mmol/L of chloride in sweat is diagnostic of cystic fibrosis.

The sweat test is conducted using pilocarpine iontophoresis. A 3mA current carries pilocarpine into the skin of the forearm stimulating local sweating. The arm is washed with distilled water and sweat collected on a filter paper or gauze. The duration of collection is usually 30-60 minutes. The filter paper is removed, weighed and eluted in distilled water. At least 50mg and preferably 100mg of sweat should be collected for

reliable results. It may not be possible to collect this amount in young infants. More than 60mmol/L of chloride is diagnostic of CF when one or more other criteria are present. In healthy adults, the sweat chloride values increase slightly, but 60mmol/L still differentiates CF from other conditions. False/negative results may be encountered in nephrotic syndromes.

[Q: 1378] OnExamination - Respiratory

A 24-year-old asthmatic female is admitted with acute severe asthma.

Which of the following statements regarding the diagnosis is correct?

- 1- Agitation should be managed with a benzodiazepine
- 2- A high inspired Oxygen concentration should be used routinely
- 3- Inhaled salmeterol is indicated as first line therapy
- 4- Normal arterial pCO₂ is reassuring
- 5- Pulsus paradoxus is a reliable sign of severity

Answer & Comments

Answer: 2- A high inspired Oxygen concentration should be used routinely

A normal or raised arterial pCO₂ is an indication of severe asthma. Pulsus paradoxus is not reliable and is not part of the criteria in assessing severity of asthma attack. Salmeterol is used in management of chronic asthma (Step 3). High dose oxygen (40-60%) should be used in severe asthma attack, together with steroids and nebulised bronchodilators. Sedation must be avoided as it can cause respiratory failure and arrest.

[Q: 1379] OnExamination - Respiratory

A 65-year-old obese man presents with night time sweats, nocturia, poor concentration and day time somnolence.

To which of the following conditions does this diagnosis predispose?

- 1- Hypoglycaemia
- 2- Hypotension
- 3- Insulin sensitivity
- 4- Osteoporosis
- 5- Sudden death

Answer & Comments

Answer: 5- Sudden death

This history is typical of sleep apnoea. Sleep apnoea is an independent risk factor for stroke (and death from all causes), and is associated with hypertension, IGT, and insulin resistance.

[Q: 1380] OnExamination - Respiratory

Which one of the following cells in the lung parenchyma produces surfactant?

- 1- Alveolar macrophage
- 2- Endothelial cell
- 3- Goblet Cell
- 4- Type I pneumocyte
- 5- Type II pneumocyte

Answer & Comments

Answer: 5- Type II pneumocyte

Surfactant is produced by type 2 pneumocytes and is responsible for the ability of the air filled, fluid lined alveoli to expand without collapse.

[Q: 1381] OnExamination -

Respiratory

Obstructive sleep apnoea characteristically associated with:

- 1- hypersomnolence
- 2- impotence
- 3- macrognathia
- 4- insomnia
- 5- polydipsia

Answer & Comments

Answer: 1- hypersomnolence

Dominant symptom = hypersomnolence (sleepiness). Other most common symptoms include apparent personality changes, witnessed apnoeas and true nocturnal polyuria. Reduced libido is less common. Sleep apnoea may be associated with acromegaly, myxoedema, obesity and micrognathia/retrognathia.

[Q: 1382] OnExamination - Respiratory

An 18 year-old female is admitted with a depression of her conscious level. Arterial blood gas analysis revealed:

pH 7.26

pO₂ 12.1 kPa

pCO₂ 3.9 kPa

standard bicarbonate 14.7 mmol/L

Which one of the following would account for these results?

- 1- Analytical error
- 2- Metabolic acidosis
- 3- Persistent vomiting
- 4- Respiratory acidosis
- 5- Respiratory alkalosis

Answer & Comments

Answer: 2- Metabolic acidosis

This patient has a metabolic acidosis with an effort at respiratory compensation as reflected by elevated pO₂ and reduced pCO₂. This could be due to poisoning or a condition such as Diabetic ketoacidosis. Vomiting would cause a metabolic alkalosis.

[Q: 1383] OnExamination - Respiratory

A 55-year-old plumber presented with a dry nocturnal cough and increasing exertional breathlessness.

On examination he had early finger clubbing, cyanosis and bilateral basal crackles. A chest X-ray showed bilateral lower zone shadowing.

Investigations revealed:

paO₂ (breathing air) 8.2 kPa (11.3-12.6)

FEV₁/FVC ratio 85%

Which of the following investigations is most likely to establish the diagnosis?

- 1- Echocardiography.
- 2- High resolution CT scan of chest
- 3- Measurement of diffusion capacity
- 4- Serum angiotensin-converting enzyme (ACE) level
- 5- Transbronchial lung biopsy

Answer & Comments

Answer: 2- High resolution CT scan of chest

[Q: 1384] OnExamination - Respiratory

Which cell type is responsible for the early asthmatic response?

- 1- Basophil
- 2- Eosinophil
- 3- Mast cell
- 4- Neutrophil
- 5- TH1-lymphocyte

Answer & Comments

Answer: 3- Mast cell

[Q: 1385] OnExamination - Respiratory

A 64-year-old man presented with shortness of breath.

On examination he had the signs of a large right-sided pleural effusion.

Investigations revealed:

pleural fluid analysis: protein 48 g/L

What is the most likely cause?

- 1- Cardiac failure
- 2- Constrictive pericarditis
- 3- Hepatic cirrhosis
- 4- Mesothelioma
- 5- Nephrotic syndrome

Answer & Comments

Answer: 4- Mesothelioma

The high protein content of the effusion suggests that it is an exudates. Mesothelioma is the only cause of an exudates in this list. The remaining choices cause a transudative effusion.

[Q: 1386] OnExamination - Respiratory

A 55-year-old man who has a 25 year pack history of smoking presents with productive cough with mucoid sputum of 2 year duration.

On examination he has scattered ronchi and wheezing. The likeliest diagnosis is :

- 1- Bronchial Asthma
- 2- Bronchiectasis
- 3- Chronic Bronchitis
- 4- Pneumonitis
- 5- Fibrosing Alveolitis

Answer & Comments

Answer: 3- Chronic Bronchitis

Chronic bronchitis is one of the most common respiratory diseases due to cigarette smoking. The smoking history and productive cough for at least 2 years is indicative of chronic bronchitis.

[Q: 1387] OnExamination - Respiratory

In a study of a new drug for asthma, a researcher wishes to compare average serum drug concentrations in volunteers, four hours after taking the drug;

* in the fasting state then

* after a meal

Which of the following would be the most appropriate statistical test to use?

- 1- chi-squared test
- 2- Pearson's correlation coefficient
- 3- Student's paired t-test
- 4- Student's unpaired t-test
- 5- Wilcoxon test

Answer & Comments

Answer: 3- Student's paired t-test

In this scenario we are dealing with use of the drug in the same volunteers with the intervention being the effect of feeding on drug concentrations. Thus you'll be comparing means in the same subjects and the paired t-test would be the most appropriate test.

[Q: 1388] OnExamination - Respiratory

A 67-year-old man presents with a long history of cough, breathlessness on minimal exertion and ankle swelling. He smokes 30-40 cigarettes per day.

Investigations are as follows:

Haemoglobin 19g/dl
 white blood count 7.3
 paO_2 (air) 6.2kPa
 paCO_2 (air) 8.9kPa
 serum $[\text{H}^+]$ 44 nmol/l
 serum $[\text{HCO}_3^-]$ 36 mmol/l

What is the most likely explanation of these results?

- 1- acute respiratory acidosis
- 2- chronic respiratory acidosis
- 3- chronic respiratory alkalosis
- 4- metabolic acidosis
- 5- metabolic alkalosis

Answer & Comments

Answer: 2- chronic respiratory acidosis

Normal range $[\text{H}^+]$ = 36-44nM. Normal range $[\text{HCO}_3^-]$ = 21 - 27.5mM. Even if you did not know the normal reference values for H^+ and HCO_3^- , you should have been able to make an intelligent guess at compensated respiratory acidosis from the clinical history, type 2 respiratory failure and probable secondary polycythaemia.

[Q: 1389] OnExamination - Respiratory

You are asked to see a patient who attends A+E with shortness of breath. The chest X-ray shows right lower lobe consolidation.

Which of the following features should prompt admission to hospital?

- 1- Audible Bronchial breathing
- 2- A paO_2 of 9.8 kPa (11-13)
- 3- A SaO_2 of 95%
- 4- A respiratory rate of 32/min
- 5- A White cell count of $16.8 \times 10^9/\text{L}$ (4-10)

Answer & Comments

Answer: 4- A respiratory rate of 32/min

The British Thoracic Society guidelines for community acquired pneumonia in adults recommend use of the CURB-65. A 6-point score, one point for each of Confusion, Urea >7 mmol/l, Respiratory rate 30/min or more, systolic Blood pressure below 90mmHg (or diastolic below 60mmHg), Age 65 years or older. If the CURB score is 1-2 then risk of death is increased and hospital admission should be considered. A CURB score of 3 or more puts the patient at high risk of death and hospital admission is warranted.

[Q: 1390] OnExamination - Respiratory

Randomised controlled trials have shown that long-term oxygen therapy (LTOT) reduces mortality in:

- 1- cryptogenic fibrosing alveolitis
- 2- cor pulmonale due to chronic airflow obstruction
- 3- asthma
- 4- cystic fibrosis
- 5- pulmonary sarcoidosis

Answer & Comments

Answer: 2- cor pulmonale due to chronic airflow obstruction

Adequate data for LTOT prolonging survival exists only for COPD although in practice it is assumed to apply in other chronic hypoxaemic lung conditions.

[Q: 1391] OnExamination - Respiratory

An otherwise healthy 32-year-old man was the driver of a car involved in a high speed RTA 3 days ago. He has sustained a closed fracture of his femur which has been treated surgically with an intramedullary nail, as well as

fractures of his right clavicle and left radius. He was managed according to ATLS protocol when he attended the emergency department. On examination, he is acutely short of breath and has a temperature of 37.5°C. The patient seems confused when you speak to him, and as you examine him, you note petechial haemorrhages.

What do you think is the most likely diagnosis?

- 1- Asthma attack
- 2- Chest infection
- 3- ?Fat embolism???
- 4- Pulmonary embolism
- 5- Tension pneumothorax

Answer & Comments

Answer: 3- ?Fat embolism???

The two diagnosis which should be considered first in this scenario are pulmonary embolism and fat embolism. Although the patient is at high risk of pulmonary embolism, and appropriate measures should be undertaken to reduce this, the clinical scenario is more suggestive of fat embolism. Fat embolism is thought to occur as a result of release of lipid globules from damaged bone marrow fat cells. Another mechanism that has been suggested is the increased mobilisation of fatty acids peripherally.

The effects that are seen clinically depend on what part of the microvasculature is affected by the lipid globules. Pulmonary symptoms are caused by ventilation - perfusion mismatch. Confusion (cerebral effects) may be seen, as well as a petechial rash caused by capillary damage in the skin.

[Q: 1392] OnExamination - Respiratory

A 48-year-old woman presented with shortness of breath, cough with heavy sputum production, and a low grade fever. She has smoked 20 cigarettes per day for 30 years. Her

arterial blood gases revealed pH of 7.4, pCO₂ of 45 mmHg (NR 35-45) and a pO₂ of 78 mmHg (NR 90-110).

What is the most likely diagnosis?

- 1- Bronchial asthma
- 2- Chronic bronchitis
- 3- Cryptogenic fibrosing alveolitis
- 4- Paraneoplastic syndrome
- 5- Pulmonary embolism

Answer & Comments

Answer: 2- Chronic bronchitis

The most likely explanation based on the symptoms and the relative hypoxia with high pCO₂ is an acute exacerbation of COAD - towards the chronic bronchitic end of the spectrum.

[Q: 1393] OnExamination - Respiratory

A 38-year-old male presents with episodic wheeze and non-productive cough which occurs particularly at night. He has been employed in the plastics industry.

Which of the following suggests a diagnosis of occupational lung disease?

- 1- Absent family history of asthma
- 2- Commencement of symptoms on his first day in this employment
- 3- elevated serum IgE concentration
- 4- Improved symptomatology when on holiday
- 5- Increased bronchial reactivity

Answer & Comments

Answer: 4- Improved symptomatology when on holiday

Episodic cough and wheeze with nocturnal symptoms are classical of asthma. Occupational asthma is the commonest

industrial lung disease with over 400 causes and accounts for up to 10% of adult onset asthma. The commonest occupations affected are spray painters, Bakers, Chemical processors, plastics workers and welders and soldering. Patients are characteristically better when on holiday. The diagnosis is confirmed by serial PEF measurements at home and at work. Recordings should be performed 2 hourly for 4 weeks or if this is not possible metacholine/histamine challenges can be undertaken after days at work and away from work. Following objective confirmation of the diagnosis the underlying cause should be identified.

[Q: 1394] OnExamination - Respiratory

An 18-year-old boy is suspected of having cystic fibrosis.

Which of the following results would be most suggestive of this condition?

- 1- Abnormal pancreatic function tests
- 2- Abnormalities in lung function tests
- 3- Bronchiectasis on a chest x-ray
- 4- Elevated sweat chloride concentration
- 5- Low immunoreactive plasma trypsinogen

Answer & Comments

Answer: 4- Elevated sweat chloride concentration

The sweat test is the most important test for CF. Up to 99% of children with CF have sweat chloride and sodium levels above 70 and 60 mM respectively. In normal children, sweat sodium is higher than chloride. The reversed ratio is another pointer to CF. Two sweat tests should be performed spontaneously on both arms with pilocarpine iontophoresis. Older children with CF and pancreatic insufficiency have low immunoreactive trypsin. This and the other tests mentioned may be suggestive of CF but are not diagnostic.

[Q: 1395] OnExamination - Respiratory

Sleep Apnoea syndrome is best diagnosed by the following:

- 1- Polygraphic Sleep Studies
- 2- therapeutic trial of amphetamines
- 3- EEG
- 4- Blood gases during apneic episodes
- 5- Presence of HLA-DR2 and DQw1

Answer & Comments

Answer: 1- Polygraphic Sleep Studies

Sleep apnoea is characterized by cessation of breathing during sleep, which causes extreme restlessness with frequent respiratory pauses and snoring during night sleep, and by daytime drowsiness and irritability. The diagnosis is established by polygraphic recording of sleep which shows periods (at least 30 of 10 or more seconds duration in 7 h of sleep) of apnoea, associated with a fall in arterial oxygen saturation.

[Q: 1396] OnExamination - Respiratory

A 9-year-old boy presents with a history of headache and persistent green nasal discharge. At night he has a cough and snores loudly. The headache is exacerbated by leaning forwards.

On examination he is afebrile, but has a persistent nasal obstruction and nasal speech. He is tender over the maxillae and forehead.

What is the most likely diagnosis?

- 1- Gastroesophageal reflux
- 2- Allergic rhinitis
- 3- Sinusitis
- 4- Asthma
- 5- Croup

Answer & Comments

Answer: 3- Sinusitis

The picture is one of upper airways obstruction associated with nasal discharge, most likely due to sinusitis. In this case the maxillary and frontal sinuses are most likely to be involved.

[Q: 1397] OnExamination - Respiratory

A 65-year-old woman, has smoked 50 cigarettes a day for 40 years. She has had increasing dyspnoea for the several years, but no cough. A Chest X-ray shows increased lung size along with flattening of the diaphragms, consistent with emphysema. Over the next several years she develops worsening peripheral oedema. Her vital signs show T° 36.7 C, P 80, RR 15, and BP 120/80 mm Hg.

Which of the following cardiac findings is most likely to be present?

- 1- Mitral valve stenosis
- 2- Constrictive pericarditis
- 3- Right ventricular hypertrophy
- 4- Left ventricular aneurysm
- 5- Non-bacterial thrombotic endocarditis

Answer & Comments

Answer: 3- Right ventricular hypertrophy

The most likely finding in this woman is pulmonary hypertension as a result of emphysema secondary to long term cigarette smoking. Peripheral oedema is due to right heart dilatation and failure. Mitral stenosis is not supported by the history. Constrictive pericarditis could be caused by a lung malignancy in this patient, but again, there is no suggestion of this in the history. Constrictive pericarditis would be characterised by soft heart sounds, a diastolic "pericardial knock", and gross signs of right heart failure. LV aneurysm would lead to

symptoms and signs of left heart failure and again is not the most likely finding suggested by the history.

[Q: 1398] OnExamination - Respiratory

A 43-year-old Caribbean female Comprehensive school teacher complains of slowly increasing breathlessness. She has no smoking history. Investigations reveal she has bilateral enlarged hilar lymph nodes, elevated serum calcium, interstitial lung disease, and enlarged liver and spleen.

What is the most likely diagnosis?

- 1- Coccidioidomycosis
- 2- Hyperparathyroidism
- 3- Hypervitaminosis D
- 4- Sarcoidosis
- 5- Tuberculosis

Answer & Comments

Answer: 4- Sarcoidosis

[Q: 1399] OnExamination - Respiratory

A 45 year-old male with type 2 diabetes presented to the clinic as his wife complained that he snored excessively.

Which of the following would suggest a diagnosis of obstructive sleep apnoea?

- 1- Daytime sleepiness
- 2- Nasal polyps
- 3- Nocturnal cough
- 4- Poor memory
- 5- Stridor

Answer & Comments

Answer: 1- Daytime sleepiness

The typical problem associated with sleep apnoea syndrome is excessive daytime

somnolence. Associated with obesity, acromegaly, hypothyroidism and Cushing's syndrome. It is felt that the somnolence is due to the interruption of REM sleep by frequent episodes of waking due to apnoeic episodes.

[Q: 1400] OnExamination -
Rheumatology

A 30-year-old woman presents with Raynaud's phenomenon.

Which one of the following clinical features suggests an underlying connective tissue disease?

- 1- History of chilblains
- 2- Involvement of toes
- 3- One previous miscarriage in early pregnancy
- 4- Symmetrical involvement of fingers
- 5- Symptoms developed as a teenager

Answer & Comments

Answer: 1- History of chilblains

A history of chilblains is suggestive of an underlying connective tissue disease.

Other features suggestive of the potential presence or later development of an underlying connective disease include the onset of digital vasospasm after the age of 30, male sex, unilateral involvement, abnormal nailfold capillary changes in microscopy, sclerodactyl, rashes and serological presence of autoantibodies.

[Q: 1401] OnExamination -
Rheumatology

A 50-year-old man presented with a six-week history of general malaise and a 2 day history of a right foot drop, a left ulnar nerve palsy and a widespread purpuric rash. He complained of arthralgia but had no clinical evidence of inflammatory joint disease.

Investigations revealed:

ESR 100 mm/hr

ANCA negative

ANA negative

Rheumatoid factor strongly positive

C3 0.8 g/L (NR 0.75 - 1.6)

C4 0.02 g/L (NR 0.14 - 0.5)

Urine dipstick Blood ++, no protein

An echocardiogram was normal and two sets of blood cultures were negative.

What is the most likely diagnosis?

- 1- ANA negative SLE
- 2- Cryoglobulinaemia
- 3- Infective endocarditis
- 4- Polyarteritis nodosa
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 2- Cryoglobulinaemia

The history is strongly suggestive of systemic vasculitis with mononeuritis multiplex, purpuric rash and haematuria. It is important to exclude conditions which can mimic vasculitis such as infective endocarditis. The normal echocardiogram and negative blood cultures make this unlikely. Whilst polyarteritis nodosa can present with exactly this clinical picture, the marked consumption of C4 together with a strongly positive rheumatoid factor strongly suggests cryoglobulinaemia as the underlying cause. Cryoglobulins are immunoglobulins which precipitate in the cold. They can be type I (monoclonal), type II (mixed monoclonal and polyclonal), or type III (polyclonal). Type I cryoglobulinaemia is associated with haematological diseases such as myeloma and Waldenstrom's. Type II and Type III cryoglobulinaemia can be associated with many connective tissue disorders, chronic infections and most importantly, hepatitis C infection which should always be excluded. Treatment of cryoglobulinaemia would include plasmapheresis, high dose steroids and Cyclophosphamide

[Q: 1402] OnExamination -

Rheumatology

Which of the following statements regarding systemic lupus erythematosus (SLE) is correct?

- 1- when disease is active the levels of complements C3 and C4 are raised.
- 2- when evidence of mild nephritis is present, a renal biopsy is unnecessary.
- 3- there is a female preponderance of 20:1.
- 4- first manifestation of the disease may be idiopathic thrombocytopenia purpura.
- 5- there is neurological involvement in about 10% of cases.

Answer & Comments

Answer: 4- first manifestation of the disease may be idiopathic thrombocytopenia purpura.

When SLE is active the serum complement is depressed. C3 and C4 levels can be used to monitor response to treatment. A poor correlation exists between the clinical manifestations and severity of renal involvement. A biopsy is essential in guiding treatment when renal involvement exists. Neurological involvement is common in SLE. Nearly 50% have neurological problems including: personality disorder, seizures, cardiovascular accidents, and a peripheral neuritis (mononeuritis multiplex).

From Hannam et al. MRCP (Paediatrics) Part 1 MCQs. page 57 © WB Saunders. Reproduced with permission.

[Q: 1403] OnExamination - Rheumatology

A 55-year-old female receiving 10 mg of Methotrexate and 5mg of folate* weekly presents with a sore right finger after cutting herself in the garden. On examination, she has a swollen, erythematous right ring finger up to the proximal interphalangeal joint and you diagnose a cellulitis. You give her a

prescription for erythromycin as she is allergic to penicillins. She has been receiving the Methotrexate for just over one year with no problems and all routine blood monitoring has been normal.

Whilst monitoring the response of the infection to treatment, what is the most appropriate strategy regarding her Methotrexate therapy?

- 1- Continue Methotrexate unchanged and increase folate supplements to 10mg daily.
- 2- Continue Methotrexate and folate unchanged.
- 3- Reduce dose of Methotrexate to 5mg weekly
- 4- Stop Methotrexate until the infection has resolved.
- 5- Stop Methotrexate only if full blood count reveals a neutropaenia.

Answer & Comments

Answer: 4- Stop Methotrexate until the infection has resolved.

In the circumstances of infection, one should consider temporarily stopping methotrexate as it is an immunosuppressant. Any infection should be treated as usual and the response to treatment monitored. Once the infection has been successfully treated methotrexate can be reinstated. However, if the patient has recurrent serious infections while taking methotrexate, its continued long term use should be discussed with the patient's rheumatologist.

*Some local variations may exist regarding dose and frequency of folate therapy. Please be aware of your local guidelines.

[Q: 1404] OnExamination - Rheumatology

A female presents with headache, lethargy and weight loss.

Which of the following would make the diagnosis of giant cell arteritis unlikely?

- 1- A normal ESR
- 2- Bilateral headache
- 3- Non-tender temporal arteries
- 4- Papilloedema on fundoscopy
- 5- The patient is 50 years old

Answer & Comments

Answer: 4- Papilloedema on fundoscopy

Patients are usually elderly with a typical age of 70 but not exclusively so. The temporal arteries are usually tender but they may be non-tender. Similarly there is usually a unilateral headache but often presents as bilateral headache. ESR is typically elevated but a normal ESR is well recognised. However, papilloedema would suggest an alternative diagnosis.

[Q: 1405] OnExamination - Rheumatology

A 33-year-old female presents with pain at the elbow which she has been aware of for the last 2 weeks.

Which of the following would be consistent with a diagnosis of tennis elbow?

- 1- Pain on pressure over the medial epicondyle
- 2- Pain on wrist extension against resistance
- 3- Pain on pronation of the forearm
- 4- Pain on flexion of the fingers against resistance
- 5- Pain on extension of the elbow

Answer & Comments

Answer: 2- Pain on wrist extension against resistance

Tennis elbow is due to lateral epicondylitis and is due to overuse/strain of the extensor

muscles of the forearm. Golfer's elbow is pain at the medial epicondyle. Consequently, there is pain over the lateral epicondyle and the pain is exacerbated by wrist extension.

[Q: 1406] OnExamination - Rheumatology

Which of the following auto-antibodies may have a role in monitoring disease activity?

- 1- Rheumatoid factor in rheumatoid arthritis
- 2- Antinuclear antibodies in systemic lupus erythematosus
- 3- Anti-Sm antibodies in systemic lupus erythematosus
- 4- Anti-ds DNA antibodies in systemic lupus erythematosus
- 5- Anti-Ro (SSA) antibodies in Sjogren's syndrome

Answer & Comments

Answer: 4- Anti-ds DNA antibodies in systemic lupus erythematosus

The serum levels of anti-dsDNA antibodies appears to correlate with disease activity in many patients and often levels will rise just before a flare of disease. The relationship is not close enough to be able to alter treatment based on a rising titre of antibodies but patients should be followed more closely in this situation. Anti-Sm antibodies are very specific for SLE but not sensitive and there is no evidence that levels change with disease activity. The only other autoantibody where there may be some correlation between levels and disease activity is cANCA in Wegener's granulomatosis.

[Q: 1407] OnExamination - Rheumatology

A 65-year-old male is referred due to inadequate pain relief for his hip osteoarthritis.

His GP has prescribed paracetamol and codeine 30mg four times daily but he has found little improvement in his pain relief.

He has a past history of asthma for which he occasionally takes an inhaler.

What is the most likely explanation for the lack of clinical efficacy associated with this medication?

- 1- Fast acetylator status
- 2- Ipratropium accelerates the metabolism of codeine
- 3- Impaired absorption of Codeine
- 4- Inadequate dose of Codeine
- 5- Interaction of Paracetamol with Codeine

Answer & Comments

Answer: 4- Inadequate dose of Codeine

The most likely explanation is that the codeine dose is inadequate.

Studies have shown that paracetamol 1g combined with codeine at dose of 60mg have the best analgesic outcomes.

Ipratropium does not increase the metabolism of codeine.

[Q: 1408] OnExamination - Rheumatology

A 40 year-old woman presents with a year history of Raynaud's phenomenon, dyspepsia and arthralgias. On examination she has sclerodactyly and synovitis of the small joints of the hands. Her ESR is 40 mm/hr (<10) but Rheumatoid factor and Antinuclear Antibody are both negative.

Which one of the following is most likely to develop as a further complication of this disorder?

- 1- anterior uveitis
- 2- butterfly rash
- 3- erosive joint disease

- 4- erythema nodosum
- 5- malabsorption

Answer & Comments

Answer: 5- malabsorption

This woman has features of a mixed connective tissue disorder like CREST/systemic sclerosis with sclerodactyly, Raynaud's, dyspepsia and arthralgia. The absence of ANA found in 90% of systemic sclerosis makes this diagnosis less likely and these antibodies plus Anti-centromere antibodies are also associated with CREST. The most likely development would be a malabsorption which is associated with hypomotility of the small intestine. Erosive arthropathy is rare as is uveitis, with Keratoconjunctivitis sicca being more common.

[Q: 1409] OnExamination - Rheumatology

A 70-year-old retired sea captain develops weakness of the shoulders and hips over a 4 month period. He has also noticed weak finger flexors with normal strength in straightening them. He has had some difficulty swallowing liquids. There is no past medical history, apart from a sexually transmitted disease picked up in the South Pacific some forty years before. This was treated with antibiotics and he is not sure of the diagnosis. He smokes a pipe and drinks 1 or 2 tots of rum at the weekend. A creatinine kinase level comes back at 120.

Which investigation is most likely to give a definite diagnosis?

- 1- Anti Jo 1 antibody titres
- 2- CT scan of the chest
- 3- EMG
- 4- Muscle biopsy with electron microscopy
- 5- 24 hour urine collection for myoglobin

Answer & Comments

Answer: 4- Muscle biopsy with electron microscopy

The diagnosis is inclusion body myositis (IBM). This is an inflammatory condition that affects the over 50s. Proximal muscles and finger flexors are predominantly involved, but distal muscle groups may also be involved. The onset of muscle weakness in IBM is generally gradual (over months or years).

IBM occurs more frequently in men than women. CK may be normal. Jo 1 titres are often raised in dermatomyositis associated with lung disease. EMG shows a similar pattern in polymyositis and IBM - small short duration motor unit arrhythmias can complicate polymyositis and dermayomyositis, but not IBM. There is no association of IBM with malignancy. Polymyositis and Dermatomyositis show a much better response to steroids than IBM. Biopsy in IBM shows intranuclear or cytoplasmic tubofilaments on electron microscopy.

[Q: 1410] OnExamination - Rheumatology

A 24-year-old male has been receiving Sulphasalazine for 6 months as treatment for Reiters disease. His most recent series of blood tests were normal.

When should he next be screened?

- 1- Two weeks
- 2- One month
- 3- Three months
- 4- Six months
- 5- One year

Answer & Comments

Answer: 3- Three months

Guidance suggests that during the first year of treatment with Sulphasalazine, FBC and LFTs should be monitored every 1-2 weeks for the first 3 months then 3 monthly for the first year and then 6 monthly thereafter.

Side effects of Sulphasalazine include Myelosuppression, macrocytosis, hypersensitivity and azoospermia in males.

[Q: 1411] OnExamination - Rheumatology

A 50-year-old female presented with a week's history of pain and stiffness in her shoulders and wrists with symptomatic deterioration in the morning. On examination, there was synovitis of both wrists and there was no proximal muscle wasting or weakness. Her ESR was 50 mm/hr (0 - 20).

What is the most likely diagnosis?

- 1- polymyalgia rheumatica
- 2- polymyositis
- 3- reactive arthritis
- 4- rheumatoid arthritis
- 5- systemic lupus erythematosus

Answer & Comments

Answer: 4- rheumatoid arthritis

In this middle aged female, the acute arthritis of shoulders and wrists together with synovitis and raised ESR are highly suggestive of acute Rheumatoid Arthritis. Weakness and myalgia would be expected with polymyositis and a rash would be expected with SLE with little evidence of a synovitis. There is no prior precipitant to suggest a reactive arthritis and synovitis would be again unusual. PMR would be less likely in this age group and weakness, weight loss without synovitis would be expected.

[Q: 1412] OnExamination -
Rheumatology

A general practice covers a population of 20,000 patients.

How many patients with Rheumatoid Arthritis would be expected in this population?

- 1- 1000
- 2- 500
- 3- 200
- 4- 100
- 5- 50

Answer & Comments

Answer: 3- 200

The prevalence of Rheumatoid Arthritis is approximately 1%. Thus in a practice of 20,000, the number of patients with Rha would be 200, a not insignificant number. Approximately 2-3 females are affected for each male.

[Q: 1413] OnExamination -
Rheumatology

Which of the following has the greatest specificity for Wegener's granulomatosis?

- 1- pANCA and positive antibodies to myeloperoxidase
- 2- atypical ANCA and positive antibodies to myeloperoxidase
- 3- cANCA and positive antibodies to myeloperoxidase
- 4- cANCA and positive antibodies to proteinase 3
- 5- cANCA and positive antibodies to lactoferrin

Answer & Comments

Answer: 4- cANCA and positive antibodies to proteinase 3

When requesting an ANCA test, both immunofluorescence and an ELISA test are generally performed. On immunofluorescence, if ANCA are present, the staining pattern may be cytoplasmic (cANCA) or perinuclear (pANCA). Typical antigen specificity includes proteinase 3 or myeloperoxidase. cANCA and specificity for the PR-3 antigen is most specific for Wegener's granulomatosis. This pattern is also seen in microscopic polyarteritis nodosa and rarely Churg-Strauss syndrome. PANCA and MPO are less specific findings detected in various vasculitic illnesses and occasionally in chronic infections.

[Q: 1414] OnExamination -
Rheumatology

A 40-year-old man presents with acute monoarthritis of the right knee. Gout is confirmed following joint aspiration and examination of the fluid under polarised light microscopy. He underwent endoscopy 3 weeks earlier because of dyspepsia and this confirmed a duodenal ulcer.

Which of the following would be the best initial treatment for him?

- 1- Allopurinol
- 2- Indomethacin alone
- 3- Indomethacin and Lansoprazole
- 4- Indomethacin and Misoprostol
- 5- Intra-articular corticosteroid injection

Answer & Comments

Answer: 5- Intra-articular corticosteroid injection

All non-steroidals including Cox-II selective non-steroidals are contra-indicated in the presence of active ulceration. Allopurinol should never be started in the presence of acute gout as the symptoms will be exacerbated. In a large joint such as the knee, the safest option would be to inject

corticosteroid into the joint. Colchicine would also be an option but is associated with GI toxicity.

[Q: 1415] OnExamination - Rheumatology

A 32-year-old woman is referred from her general practice following a presentation with shortness of breath, myalgia, arthralgia and a skin rash.

Which of the following antibodies when found in this patient is most specific for Systemic Lupus Erythematosus?

- 1- ANA
- 2- Anti-Ro
- 3- Anti-Sm
- 4- cANCA
- 5- Rheumatoid factor

Answer & Comments

Answer: 3- Anti-Sm

The presence of anti-Sm antibodies is more specific for SLE than antinuclear antibodies. Others are not specific for SLE.

[Q: 1416] OnExamination - Rheumatology

A 22-year-old boy with known hereditary angioneurotic oedema (HAO) presents with a recurrent fever, arthralgia and a rash on the face and the upper chest. Despite treatment for his HAO, he has always been troubled by recurrent attacks and has required adrenaline on several occasions. His C4 levels have been persistently reduced secondary to his HAO.

What is the most likely cause for his current symptoms?

- 1- Dermatomyositis
- 2- Drug rash
- 3- Psoriasis with arthropathy
- 4- Systemic Lupus Erythematosus

5- Viral illness

Answer & Comments

Answer: 4- Systemic Lupus Erythematosus

HAO is characterised by deficiency of C1 esterase inhibitor. This leads to persistent activation of the classical complement pathway and C4 levels are frequently low secondary to activation and consumption. If treatment fails to normalise the C4 levels and they remain persistently low, these patients are at an increased risk of developing SLE.

[Q: 1417] OnExamination - Rheumatology

A 65-year-old man complains of bone pain especially in his spine. X-ray revealed lytic lesions in the vertebrae and skull. He also had anemia and hypercalcaemia.

Which of the following is least likely to be present in this patient:

- 1- Bence Jones proteins
- 2- Decreased resistance to infection
- 3- Infiltration of flat bones by plasma cells
- 4- Macroglobulinemia
- 5- Monoclonal gammopathy

Answer & Comments

Answer: 4- Macroglobulinemia

This is multiple myeloma. Macroglobulinemia is not typical of multiple myeloma.

[Q: 1418] OnExamination - Rheumatology

A 68-year-old woman complained of pain at the base of her right thumb. There was tenderness and swelling of the right first carpo-metacarpal joint.

What is the most likely diagnosis?

- 1- avascular necrosis of the scaphoid

- 2- de Quervain's tenosynovitis
- 3- osteoarthritis
- 4- psoriatic arthritis
- 5- rheumatoid arthritis

Answer & Comments

Answer: 3- osteoarthritis

Osteoarthritis of the 1st carpometacarpal joint is extremely common and in a 68-year-old lady is the most likely diagnosis. Swelling is usually bony hard and due to osteophyte formation which can lead to the appearance of squaring of the hand. De Quervain's tenosynovitis is a common overuse condition which present with pain at the base of the thumb but is not associated with joint swelling. This joint can be affected in RA and psoriatic arthritis but rarely on its own.

[Q: 1419] OnExamination - Rheumatology

A 79-year-old woman presents with mild dyspnoea and confusion. Of note in her past medical history was a one year history of Raynaud's phenomenon.

On examination her pulse was 118 beats per minute, she had a blood pressure of 122/88 mmHg and she had a small ulcer on her right big toe.

Auscultation of her chest revealed bibasal crackles and she had mild ankle oedema.

Her investigations show:

haemoglobin 9.5 g/dl (12-16)

white cell count $3.5 \times 10^9/L$ (4-11)

platelet count $110 \times 10^9/L$ (150-400)

serum total protein 120 g/l (60-75)

serum immunoglobulins IgA 0.8 g/l (0.8-3)

IgG 15 g/l (6-13)

IgM 70 g/l (0.4-2.5)

Which of the following complications is she likely to develop?

- 1- Acute renal failure
- 2- Atypical pneumonia
- 3- Erythema repens gyratum
- 4- Hyperviscosity syndrome
- 5- Pathological bone fracture

Answer & Comments

Answer: 4- Hyperviscosity syndrome

This elderly man has a very raised IgM level, pancytopenia, Raynaud's phenomenon and a foot ulcer.

The most likely diagnosis here is Waldenstrom's Macroglobulinaemia (WM). WM refers to a condition that presents in the seventh or eighth decade of life.

It is characterized by the presence of a high level of a macroglobulin (immunoglobulin M [IgM]), elevated serum viscosity and the presence of a lymphoplasmacytic infiltrate in the bone marrow, resulting in pancytopenias.

Raynaud phenomenon may herald the onset of this condition and is due to cryoglobulinemia.

The monoclonal IgM causes hyperviscosity syndrome; cryoglobulinemia types 1 and 2; coagulation abnormalities; polyneuropathies; cold agglutinin disease and anaemia; primary amyloidosis; and tissue deposition of amorphous IgM in skin, the GI tract, kidneys, and other organs.

[Q: 1420] OnExamination - Rheumatology

A 72-year-old lady presents with pain and swelling of the left wrist. Three weeks ago she received an intra-articular steroid injection into the wrist as treatment of chronic pain which was felt to be due to osteoarthritis. On

examination, the joint is erythematous, swollen and tender. Results reveal:

White cell count $12.5 \times 10^9/L$ $4-10 \times 10^9/L$

LDH concentration 400 iu/l 0-250 iu/l

Rheumatoid Factor 34 iu/l <20 iu/l

X-ray of wrist revealed a bony destruction of the joint and wrist aspiration revealed only a dry tap.

What is the most likely diagnosis?

- 1- Acute Gout
- 2- Acute inflammatory reaction related to Osteoarthritis
- 3- Acute rheumatoid arthritis
- 4- Pyrophosphate arthropathy
- 5- Septic arthritis

Answer & Comments

Answer: 5- Septic arthritis

This patient has had an invasive procedure performed relatively recently for suggested OA. Unfortunately the risks associated with intraarticular injection includes joint infection which appears to be the case here. The positive rheumatoid factor is a red herring, is mildly positive here and is found in 2.5% of the population and may be raised in association with Ca, SLE and infection.

[Q: 1421] OnExamination - Rheumatology

A 32-year-old, previously well, female presents with a seven month history of pain and stiffness in her joints. Examination reveals synovitis of the distal interphalangeal joints of the left index finger and the right ring finger together with the left wrist and left ankle joints. The ESR was 35mm in the first hour.

Which one of the following is the most likely diagnosis?

- 1- Osteoarthritis

- 2- Psoriatic arthritis
- 3- Rheumatoid arthritis
- 4- Systemic lupus erythematosus.
- 5- Viral arthritis.

Answer & Comments

Answer: 2- Psoriatic arthritis

The lengthy history with an oligoarticular involvement but affecting the distal interphalangeal joints despite the lack of any previous history of psoriasis is suggestive of psoriatic arthropathy. The synovitis would argue against a diagnosis of OA and the absence of any other supportive features (rash) makes SLE unlikely. One would expect a more symmetrical arthropathy with RhA and it has progressed may beyond the acute period expected for a viral arthritis.

[Q: 1422] OnExamination - Rheumatology

A 32-year-old, previously well, female presents with a seven month history of pain and stiffness in her joints. Examination reveals synovitis of the distal interphalangeal joints of the left index finger and the right ring finger together with the left wrist and left ankle joints. The ESR was 35mm in the first hour.

Which one of the following is the most likely diagnosis?

- 1- Osteoarthritis
- 2- Psoriatic arthritis
- 3- Rheumatoid arthritis
- 4- Systemic lupus erythematosus.
- 5- Viral arthritis.

Answer & Comments

Answer: 2- Psoriatic arthritis

The lengthy history with an oligoarticular involvement but affecting the distal

interphalangeal joints despite the lack of any previous history of psoriasis is suggestive of psoriatic arthropathy. The synovitis would argue against a diagnosis of OA and the absence of any other supportive features (rash) makes SLE unlikely. One would expect a more symmetrical arthropathy with RhA and it has progressed may beyond the acute period expected for a viral arthritis.

[Q: 1423] OnExamination - Rheumatology

A 50-year-old woman presents with dry eyes, a dry mouth, an erythematous rash and polyarthralgia.

Investigations show:

Anti-nuclear antibody strongly positive (1:1600)

Anti-Ro/SSA antibodies strongly positive

Rheumatoid factor positive

IgG 45 g/L (NR <15)

IgM normal

IgA normal

Kappa/lambda ratio normal

What is the most likely diagnosis?

- 1- Hyperviscosity syndrome
- 2- Myeloma associated vasculitis
- 3- Primary Sjogren's Syndrome
- 4- Rheumatoid arthritis with secondary Sjogren's Syndrome
- 5- Systemic Lupus Erythematosus

Answer & Comments

Answer: 3- Primary Sjogren's Syndrome

The clinical features and the serology are typical of primary Sjogren's Syndrome (occurs alone and more likely to have positive anti Ro SSA antibodies than secondary sjogren's). Hypergammaglobulinaemia is present in 80% of individuals. ANA and Anti-Ro/SSA

antibodies are present in approximately 90% of individuals as is a weakly positive rheumatoid factor. The normal kappa/lambda ratio confirms the hypergammaglobulinaemia is polyclonal. Typically secondary sjogren's has pre-existent Rheumatoid or SLE before the development of Sjogren's symptoms.

[Q: 1424] OnExamination - Rheumatology

A 50-year-old woman complains of arthritis and swelling of approximately 4 months duration. On examination, she has a symmetrical inflammation with painful movements of the hands and feet and also swelling of both knees, suggesting a diagnosis of rheumatoid arthritis.

Regarding her joint disease, which of the following suggest an adverse prognosis?

- 1- Acuteness of presentation
- 2- Articular erosions on X-ray
- 3- Elevated C-reactive protein
- 4- Enthesitis
- 5- Sero-negative for Rheumatoid Factor

Answer & Comments

Answer: 2- Articular erosions on X-ray

Articular erosions in rheumatoid arthritis occurring early on in the course of the disease, especially within the first 6 months of presentation, indicate a poor prognosis.

Over time joint damage will relate to disability. A positive rheumatoid factor is associated with more severe erosive disease, extra-articular manifestations including subcutaneous nodules and increased mortality. An acute onset of presentation is not a poor prognostic factor.

Raised inflammatory markers (CRP, ESR) and the duration of the early morning stiffness both correlate with disease activity.

[Q: 1425] OnExamination -
Rheumatology

Which of the following is a pro-inflammatory cytokine?

- 1- C-Reactive Protein
- 2- IL-4
- 3- IL-10
- 4- Serum amyloid precursor protein
- 5- Tumour Necrosis Factor alpha

Answer & Comments

Answer: 5- Tumour Necrosis Factor ?alpha

C-Reactive Protein and Serum Amyloid Precursor protein are acute phase reactants. IL-4 and IL-10 are anti-inflammatory cytokines. TNF-alpha is a pro-inflammatory cytokine. In inflammatory disorders such as rheumatoid arthritis, the levels of TNF-alpha are markedly elevated in inflamed joints. Treatments directed at the inhibition of TNF-alpha such as Infliximab (a monoclonal antibody against TNF-alpha) have been shown to be very effective in the treatment of rheumatoid arthritis and also effective in fistulating Crohn's disease.

[Q: 1426] OnExamination -
Rheumatology

A 25-year-old student presents to casualty with a systemic illness. She appears unwell, with a swinging fever, 3kg weight loss over 2 months, generalised myalgia, polyarthralgia affecting wrists, knees, ankles, elbows and metacarpophalangeal joints, and a sore throat. Investigations demonstrate normochromic normocytic anaemia 9.8g/l, ESR 81 mm in the first hour, CRP 31g/l, serum ferritin 1756mg/dl, RF negative, ANA negative, ENA negative, ASO titre <200iu.

What is the most likely diagnosis?

- 1- Seronegative rheumatoid arthritis
- 2- Adult onset Still's disease

- 3- Systemic lupus erythematosus
- 4- Polymyositis
- 5- Rheumatic fever

Answer & Comments

Answer: 2- Adult onset Still's disease

The clinical scenario fulfils the diagnostic criteria for Adult onset Still's disease (J Rheumatol. 1992 Mar;19(3):424-30). The fever occurs once or twice daily and is described as quotidian or diquotidian returning to 37° or below between episodes. The characteristic evanescent salmon-coloured non-pruritic macular or macular-papular rash occurs in approximately 90% of patients and is often only seen when the patient is febrile and is easily missed. A very high serum ferritin level commonly occurs in AOSD but is not diagnostic, as ferritin levels of this magnitude can also occur in sepsis and in tuberculosis.

[Q: 1427] OnExamination -
Rheumatology

A 30-year-old male presents with a week history of a painful right leg. Past medical history reveals that he had erythema nodosum and recurrent oral and scrotal ulceration. Examination reveals a diffusely swollen left leg.

What is the most likely cause of his swollen leg?

- 1- Cellulitis
- 2- Lymphoedema
- 3- Pyomyositis
- 4- Ruptured popliteal (Baker's) cyst
- 5- Venous thrombosis

Answer & Comments

Answer: 5- Venous thrombosis

This man has clinical features of Behcet's Syndrome. He has had erythema nodosum (EN). 50% of patients with Behcet's have an episode of EN throughout the course of the disease. The condition is a systemic vasculitis typified by recurrent aphthous ulcers, genital ulcers, uveitis and skin lesions. Venous thrombosis is a characteristic manifestation of Behcet's. The most likely cause of this man's swollen leg is therefore venous thrombosis.

[Q: 1428] OnExamination - Rheumatology

A 72-year-old man presents with an acutely painful right knee. On examination, he had a temperature of 37°C with a hot, swollen right knee. Of relevance amongst his investigations, was his white cell count which was $12.6 \times 10^9/L$ and a knee X-ray revealed reduced joint space and calcification of the articular cartilage. Culture of aspirated fluid revealed no growth.

What is the most likely diagnosis?

- 1- gout
- 2- Psoriatic monoarthropathy
- 3- Pseudo-gout
- 4- rheumatoid arthritis
- 5- septic arthritis

Answer & Comments

Answer: 3- Pseudo-gout

This is a typical presentation of pseudo-gout / Calcium pyrophosphate arthropathy with evidence of osteoarthritis, calcification of the articular cartilage and no growth on culture. The differential does include gout but there is nothing else within the history to suggest this as the diagnosis. Distinguishing between the two depends on analysis of the crystals with CPP crystals demonstrating a positive birefringence and urate crystals demonstrating a negative birefringence.

[Q: 1429] OnExamination - Rheumatology

A 45-year-old man has noted pain in his right knee for several years. There is no joint swelling. As he moves about during the day, the pain decreases.

The underlying disease process is probably which of the following?

- 1- Osteoarthritis
- 2- Osteochondroma
- 3- Osteomalacia
- 4- Osteopetrosis
- 5- Osteoporosis

Answer & Comments

Answer: 1- Osteoarthritis

Osteoarthritis usually involves a larger joint. The pain usually diminishes with movement, but recurs with reuse or prolonged use of the affected joint. Osteoporosis would be uncommon in a 45-year-old male. Back pain is a more typical symptom for osteoporosis. Osteochondroma could be located about the knee, but the pain would probably be exacerbated by movement or local trauma. The findings with osteomalacia would be similar to osteoporosis, and back pain would be more typical. Osteopetrosis, an uncommon inherited metabolic disorder, leads to 'brittle bones' that predispose to fractures.

[Q: 1430] OnExamination - Rheumatology

Which of the following statements is true of the immunology of rheumatoid arthritis?

- 1- It is an example of an organ-specific disease.
- 2- Joint damage is the consequence of mast cell degranulation.
- 3- It is likely that joint specific Antigens have been sequestered during the time when

immunological tolerance was being established.

- 4- Rheumatoid factor is detected by a test utilising the patients B lymphocytes.
- 5- Rheumatoid factor is an antibody with reactivity to the heavy chain of IgG.

Answer & Comments

Answer: 5- Rheumatoid factor is an antibody with reactivity to the heavy chain of IgG.

Rheumatoid arthritis is associated with several antibodies such as rheumatoid factor, collagen antibody, capable of reaction at sites other than the joints. Additionally, the disease is not confined to the joints. Damage is mediated by several means, including macrophages activated by CD4+ T cells, and by complement fixing immune complexes. There is no evidence for the creation of joint-specific antibodies in development. All the components of the joint are present during fetal life. The Rheumatoid factor test utilizes the patient's serum, to agglutinate cells coated with antibody. Rheumatoid factor (RF) is an antibody whose specificity is directed to a domain situated within the Fc portion of IgG. The rheumatoid factor may be of IgM, IgG or IgA class. The conventional (agglutination) test, detects only IgM RF.

[Q: 1431] OnExamination - Rheumatology

A 52-year-old female with type 2 diabetes presents with a two month history of painful hands and feet. Investigations confirm a diagnosis of sero-positive erosive rheumatoid arthritis. She has some pain relief from non-steroidal anti-inflammatory agents. She currently takes metformin 500 mg tds and has good glycaemic control as reflected by a HbA1c of 6.7%.

Which of the following DMARDS would be most appropriate initial treatment of her early Rheumatoid Arthritis?

- 1- Ciclosporin
- 2- Etanercept
- 3- Hydroxychloroquine
- 4- IM Gold
- 5- Methotrexate

Answer & Comments

Answer: 5- Methotrexate

Guidance recommends the use of DMARDS early in the treatment of Rheumatoid arthritis maintaining function and reducing progression of the disease (SIGN 2001). First line agents include methotrexate and sulphasalazine (SIGN 2000) and most subjects receive Methotrexate. Generally gold is considered more toxic than the former two and hydroxychloroquine is probably less effective. Ciclosporin is again rather more toxic than either methotrexate or sulphasalazine, with nephrotoxicity and immunosuppression and is generally reserved for RhA with systemic features such as vasculitis.

The TNF alpha antagonists, etanercept and infliximab, are generally reserved for individuals unresponsive to traditional DMARDS*.

[Q: 1432] OnExamination - Rheumatology

A 70-year-old man developed acute monoarthritis of his right ankle on the second postoperative day following an elective inguinal hernia repair. He was on a diuretic for hypertension. On examination his temperature was 38 C.

What is the most likely diagnosis?

- 1- Acute rheumatoid arthritis
- 2- Gout
- 3- Pseudogout
- 4- Septic arthritis

5- Traumatic synovitis

Answer & Comments

Answer: 2- Gout

The most likely diagnosis is gout, given the history of recent surgery and diuretic use.

Pyrophosphate arthropathy is less common, associated with deposition of pyrophosphate chiefly in the knees, second and third metacarpophalangeal joints and there may be a history of haemochromatosis.

Rheumatoid arthritis most commonly manifests as a chronic polyarthritis and synovitis.

Septicaemia following an elective hernia repair would be uncommon as would traumatic synovitis.

Why the fever you may ask? Gout is an inflammatory process and this is what causes the fever.

Fever may even be the most prominent feature of an attack of gout (i.e. it may be a cause of fever of unknown origin - it would suggest an inadequate history and examination of a patient with fever had been taken as well of course!). Recent Prog Med. 1998 Jan;89(1):30-6. Acute gout is a cause of Systemic inflammatory response syndrome (SIRS) (N Z Med J. 1999 Nov 12;112(1099):434-5) which is 2 or more changes of body temperature, heart rate, respiratory function, and peripheral leukocyte count

[Q: 1433] OnExamination - Rheumatology

A 16-year-old girl presents with a 3 month history of polyarthralgia and marked early morning stiffness. Her symptoms respond well to Diclofenac but she is becoming increasingly concerned about her symptoms which appear to be progressing. She is

otherwise well apart from a history of acne which is well controlled on Minocycline. Her mother has severe rheumatoid arthritis.

Investigations:

ESR 50 mm/hr

CRP 100 mg/l

Rheumatoid factor negative

ANA strongly positive (1:1600)

Anti-dsDNA antibodies negative

IgG 25 g/l (normal <15)

What is the most likely cause?

1- Systemic Lupus Erythematosus

2- Drug-induced SLE

3- Fibromyalgia

4- Rheumatoid arthritis

5- Sero-negative spondyloarthropathy

Answer & Comments

Answer: 2- Drug-induced SLE

The history strongly suggests an inflammatory problems and the elevated ESR and CRP confirm this. Rheumatoid arthritis and connective tissue disorders such as SLE would be on the differential diagnosis. The serology is atypical for rheumatoid arthritis and the marked elevation of the CRP would be very unusual for SLE where characteristically, CRP elevation indicates underlying bacterial infection or widespread serositis. The most likely diagnosis is drug-induced SLE. Minocycline has been well documented as a cause of drug-induced SLE. Characteristically, the ESR and CRP are both markedly elevated, the ANA is strongly positive and there is a hypergammaglobulinaemia. Anti-dsDNA antibodies are usually negative. Symptoms usually improve following withdrawal of the drug but can take several months to resolve.

[Q: 1434] OnExamination -
Rheumatology

A 50-year-old man presents with lethargy, polyuria, polydipsia and pain and stiffness of the hands. He has evidence of an arthropathy affecting the 2nd and 3rd metacarpophalangeal joints of both hands with X-ray evidence of degenerative disease at these sites. He also has 5cm hepatomegaly.

Which of the following is the most likely diagnosis.

- 1- Gout
- 2- Osteoarthritis
- 3- Rheumatoid arthritis with amyloidosis
- 4- Pyrophosphate arthropathy
- 5- Haemochromatosis

Answer & Comments

Answer: 5- Haemochromatosis

There are several rheumatic manifestations of haemochromatosis. Classically there is a non-inflammatory degenerative arthropathy affecting the 2nd and 3rd MCP joints with hook-like osteophytes on X-ray. These joints are rarely involved in primary osteoarthritis. Other joints can also become involved especially the hips, knees and shoulders and occasionally the joint disease can resemble rheumatoid arthritis. Other rheumatic manifestations include acute pseudogout (pyrophosphate arthropathy) which presents as an acute monoarthritis, asymptomatic chondrocalcinosis and osteoporosis.

[Q: 1435] OnExamination -
Rheumatology

A 73-year-old male presented with an acute attack of gout in his left knee.

What is the most likely underlying metabolic cause?

- 1- decreased renal excretion of uric acid
- 2- endogenous overproduction of uric acid

- 3- excessive dietary purine intake
- 4- lactic acidosis
- 5- starvation

Answer & Comments

Answer: 1- decreased renal excretion of uric acid

The aetiology of gout can broadly be divided into cases where there is underexcretion of urate via the kidney (90%) or endogenous overproduction of uric acid (10%) although in practical terms the distinction is rarely made as it allopurinol is the mainstay of long-term treatment (not during the acute attack!) in both groups. In a 73-year-old man it is almost certainly reduced renal excretion due to deteriorating renal function and possibly diuretic use. Excessive dietary intake of purines is unlikely to be the main cause in this case.

[Q: 1436] OnExamination -
Rheumatology

A 45-year-old woman notices that she develops tingling and numbness over the palmar surface of her thumb, index, and middle fingers after several hours at her computer workstation doing word processing. Pain in the same area often occurs at night as well.

Which of the following pathologic findings accounts for her symptoms?

- 1- Gout
- 2- Hypertrophic osteoarthropathy
- 3- Localized tenosynovitis
- 4- Rheumatoid arthritis
- 5- Toxic peripheral neuropathy

Answer & Comments

Answer: 3- Localized tenosynovitis

She has carpal tunnel syndrome, an entrapment neuropathy of median nerve. In this lady, tenosynovitis is worsened by repetitive motion i.e. repetitive strain injury.

[Q: 1437] OnExamination - Rheumatology

A 68-year-old woman complained of pain at the base of her right thumb. There was tenderness and swelling of the right first carpo-metacarpal joint.

What is the most likely diagnosis?

- 1- Avascular necrosis of the scaphoid
- 2- De Quervain's tenosynovitis
- 3- Osteoarthritis
- 4- Psoriatic arthritis
- 5- Rheumatoid

Answer & Comments

Answer: 3- Osteoarthritis

Osteoarthritis of the 1st carpometacarpal joint is extremely common and in a 68-year-old lady is the most likely diagnosis. Swelling is usually bony hard and due to osteophyte formation which can lead to the appearance of squaring of the hand. De Quervain's tenosynovitis is a common overuse condition which presents with pain at the base of the thumb but is not associated with joint swelling. This joint can be affected in rheumatoid arthritis and psoriatic arthritis but rarely on its own.

[Q: 1438] OnExamination - Rheumatology

A 23-year-old female presents with a left knee joint pain and a 2 month history of weight loss. She has a good appetite but has had occasional episodes of diarrhoea over this time and tends to pass a loose motion at least twice daily. She is taking no medication but there is a family history of

hypothyroidism. She is a non-smoker and drinks modest quantities of alcohol. Examination reveals a swollen, tender left knee joint with a small effusion.

The most likely diagnosis is?

- 1- Behcet's disease
- 2- Reiter's syndrome
- 3- Inflammatory bowel disease
- 4- Tuberculosis
- 5- Thyrotoxicosis

Answer & Comments

Answer: 3- Inflammatory bowel disease

The description of weight loss, diarrhoea and a mono/oligo-arthritis suggests a diagnosis of inflammatory bowel disease. Reiter's is unlikely to present with oligoarthritis and the diarrhoea is usually acute.

[Q: 1439] OnExamination - Rheumatology

A 23-year-old female presents with a left knee joint pain and a 2 month history of weight loss. She has a good appetite but has had occasional episodes of diarrhoea over this time and tends to pass a loose motion at least twice daily. She is taking no medication but there is a family history of hypothyroidism. She is a non-smoker and drinks modest quantities of alcohol. Examination reveals a swollen, tender left knee joint with a small effusion.

The most likely diagnosis is?

- 1- Behcet's disease
- 2- Reiter's syndrome
- 3- Inflammatory bowel disease
- 4- Tuberculosis
- 5- Thyrotoxicosis

Answer & Comments

Answer: 3- Inflammatory bowel disease

The description of weight loss, diarrhoea and a mono/oligo-arthritis suggests a diagnosis of inflammatory bowel disease. Reiter's is unlikely to present with oligoarthritis and the diarrhoea is usually acute.

[Q: 1440] OnExamination - Rheumatology

A 20-year-old Caucasian lady presents with typical erythema nodosum. She has a low grade fever and bilateral ankle arthritis but no other symptoms and has no medical history. There is no history of travel abroad and she is on no medication.

Which of the following would be the most appropriate investigation for this patient?

- 1- Barium enema
- 2- Chest x-ray
- 3- ESR
- 4- Upper GI endoscopy
- 5- Viral titres

Answer & Comments

Answer: 2- Chest x-ray

Erythema Nodosum is commonly idiopathic. It can also be related to streptococcal infections, acute sarcoidosis or related to drugs such as the oral contraceptive pill, Sulphonamides and Penicillins. Rarer causes include inflammatory bowel disease, TB, Behçet's Disease and other connective tissue disorders. In this case, a chest x-ray would be the most helpful investigation as this may identify bilateral hilar lymphadenopathy which together with a bilateral ankle arthropathy would strongly support a diagnosis of acute sarcoidosis. Investigation of the bowel is unlikely to help in the absence

of any bowel symptoms. Viral titres and ESR are non-specific.

[Q: 1441] OnExamination - Rheumatology

A 42-year-old woman presents with a six month history of dyspepsia. She has a 3 year history of Raynaud's phenomenon.

On examination she had telangiectasia. Her investigations reveal an ESR of 40 mm/hr (0-10) and positive anticentromere antibodies.

Which of the following is a typical late complication of this disorder?

- 1- Alopecia
- 2- Butterfly skin rash
- 3- Erosive polyarthropathy
- 4- Myositis
- 5- Pulmonary hypertension

Answer & Comments

Answer: 5- Pulmonary hypertension

Limited scleroderma is characterised by Raynaud's phenomenon, peripheral skin involvement, skin calcification, telangiectasia, nail fold capillary dilatation and anti-centromere antibodies in 70-80% of patients.

Pulmonary hypertension with or without interstitial lung disease is a characteristic late complication of this disorder.

[Q: 1442] OnExamination - Rheumatology

A 52-year-old woman presented with a two week history of malaise and lower limb joint pain, associated with a vasculitic rash over her shins, thighs and buttocks.

Investigations revealed:

haemoglobin 9.8 g/dL (11.5-16.5)

platelet count $275 \times 10^9/L$ (150-400)

serum creatinine concentration 452 mmol/L (60-110)

antinuclear antibodies Negative

antineutrophil cytoplasmic antibodies Negative

antiglomerular basement membrane antibodies Negative

dipstick urinalysis blood +++

protein +

What is the most likely diagnosis?

- 1- amyloidosis
- 2- haemolytic uraemic syndrome
- 3- Henoch-Schönlein nephritis
- 4- membranous nephropathy
- 5- myeloma

Answer & Comments

Answer: 3- Henoch-Schönlein nephritis

The distribution of the rash together with lower limb joint pains and renal involvement are most suggestive of Henoch-Schönlein purpura. This usually occurs in children aged 2-10 years but can occur in any age group. The only way of differentiating this condition from other small vessel vasculitides is by biopsy the hallmark being IgA deposition in vessel walls on direct immunofluorescence. Membranous nephropathy is a histological diagnosis and usually presents with proteinuria only as does amyloidosis. Myeloma can rarely cause vasculitis which is ANCA negative but this is rare and unlikely. HUS causes haemoglobinuria rather than an active renal sediment.

[Q: 1443] OnExamination - Rheumatology

A 28-year-old woman without any past medical history presents with a 3 month history of arthralgia. She had no past medical history of note.

Examination reveals swelling of the distal interphalangeal joints of the middle and ring fingers of the hand and wrist on the right plus a swollen left ankle.

Investigations show:

ESR 40 mm/hr (0-10)

Which of the following is the most likely diagnosis?

- 1- Acute exacerbation of osteoarthritis
- 2- Psoriatic arthropathy
- 3- Rheumatoid arthritis
- 4- Reactive arthritis
- 5- Systemic lupus erythematosus

Answer & Comments

Answer: 2- Psoriatic arthropathy

This woman has psoriatic arthritis. Synovitis is indicative of an inflammatory arthritis.

Rheumatoid arthritis typically effects the metacarpophalangeal and proximal interphalangeal joints symmetrically. Psoriatic arthritis effects the distal interphalangeal joints and tends to be asymmetrical.

Joint involvement in systemic lupus erythematosus occurs in the form of a polyarticular arthralgia, frequently symmetrical and episodic.

Intense tendonitis is more common than synovitis and can lead to deforming reversible subluxation of joints without erosive disease (Jaccoud's arthropathy).

A short, striking history of marked, acute polyarticular symptoms occurs with systemic (viral) infection.

[Q: 1444] OnExamination - Rheumatology

A 35-year-old female presents with malaise, thirst and increasing nocturia over the last month. Six months ago she attended the

Emergency Department with an episode of renal colic. One month previously her GP had noted an eruptive, painful, erythematous rash on the anterior shins, which was self-limiting.

What is the likely cause of her symptoms?

- 1- Hypercalcaemia
- 2- Hyperglycaemia
- 3- Hypocalcaemia
- 4- Hypokalaemia
- 5- Hyperoxaluria

Answer & Comments

Answer: 1- Hypercalcaemia

This lady appears to have Sarcoid, given the nephrolithiasis secondary to hypercalcaemia and erythema nodosum.

[Q: 1445] OnExamination - Rheumatology

A 25-year-old lady gives birth to a baby with complete heart block who subsequently requires pacemaker insertion.

Which of the following antibodies is most likely to be detected in the maternal serum?

- 1- Anti-dsDNA antibodies
- 2- Anti-endomysial antibodies
- 3- Anti-Ro/SSA antibodies
- 4- Anti-SCL70 antibodies
- 5- Rheumatoid factor

Answer & Comments

Answer: 3- Anti-Ro/SSA antibodies

The majority of cases of congenital heart block are due to the presence of anti-Ro/SSA antibodies in the maternal serum. The mother may have no evidence of a connective tissue disorder. The risks of congenital heart block in mothers with anti-Ro/SSA antibodies remains very small (<3%) but the correlation between the presence of anti-Ro/SSA

antibodies and congenital heart block is very strong. The heart block is generally permanent (unlike other features of neonatal lupus) and insertion of a permanent pacemaker is frequently required.

[Q: 1446] OnExamination - Rheumatology

Bone densitometry performed on a 48-year-old woman demonstrates bone mass decreased more than 2 standard deviations below the mean for her age in her left femoral head, wrist, and lumbar vertebral region.

Six months later, the amount of bone loss is seen to be increased by repeat densitometry examination.

These findings are most likely to be associated with which of the following serum laboratory test abnormalities?

- 1- Intact parathormone of 5 pmol/L (1.2 - 5.8)
- 2- Cortisol of 2060 mmol/L (110 - 607)
- 3- Total serum globulin of 35 g/L
- 4- Uric acid of 930 micromol/L (149 - 446)
- 5- Total cholesterol of 10 mmol/L (< 5.17)

Answer & Comments

Answer: 2- Cortisol of 2060 mmol/L (110 - 607)

She has osteoporosis with decreased bone mass. Most cases do not have a specific etiology, but Cushing's syndrome with hypercortisolism can promote osteoporosis. Her age should make you suspicious. Hypoparathyroidism is not going to accelerate bone loss. The bone resorption that accompanies hyperparathyroidism can cause osteoporosis. Over 95% of cases of osteoporosis are 'primary' with unknown cause. Elevated serum globulin should make you suspect a monoclonal gammopathy, but myeloma leads to focal bone lytic lesions. Hyperuricemia can be associated with gout

that can cause focal bone destruction near affected joints, the bone mass overall is not decreased.

[Q: 1447] OnExamination - Rheumatology

A 52-year-old man who has a long history of chronic alcohol abuse presents with gouty tophi. He is commenced on allopurinol but develops severe joint pains two days later. On examination he has a temperature of 39 C, and erythematous swelling of his hands, knees and ankles.

Investigations reveal:

urate 0.55 mmol/L (0.23-0.46)

c-reactive protein 150 mg/L (< 10)

Which of the following is the most likely cause for his presentation?

- 1- Acute Pyrophosphate arthropathy
- 2- Acute rheumatoid arthritis
- 3- Allopurinol allergy
- 4- Septic arthritis
- 5- Treatment with allopurinol

Answer & Comments

Answer: 5- Treatment with allopurinol

This man is having an acute attack of gout following the initiation of antihyperuricaemic (allopurinol) therapy.

This can be minimised by not starting allopurinol immediately during or shortly after an acute attack of gout, abstaining from alcohol bingeing and gradually increasing the dose of allopurinol.

Alcohol ingestion may also trigger an acute attack of gout, but in this case given the recent commencement of allopurinol, this is more likely to be the trigger.

The most common features of allopurinol hypersensitivity is rash and fever. Joint sepsis

affecting multiple joints is unlikely. Acute pseudogout presents with inflammation of the larger joints, the knees being most commonly affected.

[Q: 1448] OnExamination - Rheumatology

A 28-year-old man presented with acute stiffness and swelling of his knees and ankles, and a painful rash on his legs. The ESR was 86 mm in the first hour. Chest X-ray showed hilar lymphadenopathy.

What is the most likely outcome?

- 1- chronic arthritis
- 2- pulmonary fibrosis
- 3- renal failure
- 4- skin ulceration
- 5- spontaneous improvement

Answer & Comments

Answer: 5- spontaneous improvement

The description is typical of acute sarcoidosis with erythema nodosum, oligoarthropathy and hilar lymphadenopathy. This has a good prognosis and usually resolves spontaneously over 6-8 weeks.

[Q: 1449] OnExamination - Rheumatology

A 78-year-old man presents with an acute onset of severe pain and swelling of the left wrist which had developed since he had a chest infection two weeks previously. On examination, he had a temperature of 38°C and the left wrist was red, swollen and painful.

What is the most appropriate investigation for this patient?

- 1- Erythrocyte sedimentation rate
- 2- Full blood count
- 3- Joint aspiration

4- Serum urate concentration

5- X-ray of the joint

Answer & Comments

Answer: 3- Joint aspiration

The most relevant investigation with anyone with a red, swollen and painful joint would be joint aspiration sending off for cultures and analysis for crystals. Differential diagnoses include gout (where serum urate may fall during acute attack), pseudogout and infection. All diagnoses would be adequately addressed by joint aspiration.

[Q: 1450] OnExamination - Rheumatology

A 75-year-old man has persistent back pain for several months that is unrelated to physical activity. He has lost 12 kg in weight during this time.

Laboratory findings include a White cell count of $6.7 \times 10^9/L$ with a differential of 70 segs, 8 bands, 2 metamyelocytes, 15 lymphocytes, 5 monocytes, and 2 nucleated RBCs/100 WBCs. Haemoglobin is 11.2 g/dL, Haematocrit 33.3%, MCV 88 fL, and platelet count $89 \times 10^9/L$.

The Biochemistry shows a sodium concentration of 144 mmol/L, potassium 4.5 mmol/L, chloride 100 mmol/L, bicarbonate of 26 mmol/L, urea 14 mmol/L, creatinine 90 mmol/L, and a glucose of 5.4 mmol/L.

A CT scan of the spine reveals scattered 0.4 to 1.2 cm bright lesions in the vertebral bodies.

Which of the following additional laboratory test findings is he most likely to have?

- 1- Blood culture positive for *Neisseria gonorrhoeae*
- 2- Parathyroid hormone, intact, of 100 pg/mL (normal < 65)
- 3- Positive serology for *Borrelia burgdorferi*
- 4- Serum calcium of 1.4 mmol/L

5- Serum prostate specific antigen of 35 microgram/L

Answer & Comments

Answer: 5- Serum prostate specific antigen of 35 microgram/L

A prostatic adenocarcinoma should be the first guess (particularly in a male!) with osteoblastic (bone-forming) tumor metastases. Extensive metastases can act as a myelophthitic process that leads to peripheral blood leukoerythroblastosis. His cancer may be causing urinary tract obstruction. Hyperparathyroidism should be accompanied by increased bone lucency. Hypocalcemia is not typically related to bone disease. Lyme disease can be associated with an arthritis, but not bone lesions.

[Q: 1451] OnExamination - Rheumatology

A 73-year-old female presents with difficulty opening jars and bottles. On examination there was tenderness with crepitus and bony swelling over the base of the first metacarpal and wasting of the right thenar eminence. Investigations reveal an ESR of 30 mm/1st hr (0-20), a C-reactive protein of 8mg/L (<10), a Urate concentration of 0.40 mmol/L (0.19-0.36) and her Rheumatoid factor was 60 IU/L (<30). An x-ray of the right hand showed a loss of the joint space with articular sclerosis and osteophytes of the first carpo-metacarpal joint.

What is the most likely diagnosis?

- 1- DeQuervain's tenosynovitis
- 2- Gouty arthritis
- 3- Osteoarthritis
- 4- Pyrophosphate arthritis
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 3- Osteoarthritis

This woman has clinical and radiological features consistent with osteoarthritis (OA) of the 1st right carpometacarpal (CMC) joint. OA is characterised by joint pain, crepitus, stiffness after mobility, and limitation of motion. The CMC joint is involved in gripping and twisting. The clinical joint symptoms are associated with defects in the articular cartilage and underlying bone, outlined in this woman's x-ray findings. Joint swelling is bony in nature, unlike the boggy swelling which occurs in inflammatory arthritis. This woman's ESR is not significantly raised and her CRP is within normal range making an inflammatory arthritis unlikely. A positive rheumatoid factor does not make the diagnosis of rheumatoid arthritis. The frequency of positive rheumatoid factor in normal individuals of age > 70 is upto 10-20%. Thenar wasting occurs in OA of the 1st CMC joint due to disuse.

[Q: 1452] OnExamination - Rheumatology

A 35-year-old female presents with a 6 month history of joint pain and stiffness of hands and feet. Examination reveals a synovitis of the distal interphalangeal joints of the left index finger and the right ring finger together with the right wrist and ankle joints. Her ESR was 35 mm/hr (0-10).

Which one of the following conditions is most likely to exhibit this pattern of joint involvement?

- 1- Osteoarthritis
- 2- Psoriatic arthritis
- 3- Rheumatoid arthritis
- 4- Reactive arthritis
- 5- Systemic lupus erythematosus

Answer & Comments

Answer: 2- Psoriatic arthritis

This woman is most likely to have psoriatic arthritis. Psoriatic arthritis has been subclassified according to different patterns of arthritis: asymmetrical oligoarthritis, symmetric polyarthritis, spondyloarthropathy and arthritis mutilans. In about 20% of patients there is a chronic, progressive, and deforming arthropathy with an asymmetrical pattern, including distal interphalangeal joint involvement. Osteoarthritis in this age group is unlikely. Rheumatoid arthritis is a symmetrical arthritis typically affecting the metacarpophalangeal joints bilaterally. Arthritis does occur in systemic lupus erythematosus, however there are several other clinical features that are form part of the diagnostic criteria. Viral arthritis is self-limiting.

[Q: 1453] OnExamination - Rheumatology

A 35-year old woman who was two months postpartum presented with a four-week history of joint pain, skin rash and fever. The ESR was 40 mm / hour.

What is the most likely diagnosis?

- 1- reactive arthritis
- 2- rheumatoid arthritis
- 3- sarcoidosis
- 4- systemic lupus erythematosus
- 5- Viral arthritis

Answer & Comments

Answer: 4- systemic lupus erythematosus

This is a poor question. The symptoms are non-specific and to answer one needs to know the nature and distribution of the rash and the severity and pattern of the fever. SLE is the most likely to give a combination of joint pains, rash and fever. Documented

persistent or recurrent fevers are not generally a feature of the other conditions. The fact that the patient is 2 months postpartum is irrelevant.

[Q: 1454] OnExamination - Rheumatology

A 70-year-old man complains of pain and stiffness in both his shoulders. He has lost 1 stone in last 8 weeks and complains of feeling lethargic with loss of appetite. Investigations revealed a very high ESR (100 mm/hr), normochromic normocytic anaemia and a positive rheumatoid factor.

The most likely diagnosis is:

- 1- Polyarteritis nodosa
- 2- Polymyalgia Rheumatica
- 3- Polymyositis
- 4- Rheumatoid Arthritis
- 5- SLE

Answer & Comments

Answer: 2- Polymyalgia Rheumatica

This condition is polymyalgia Rheumatica. It is associated with weight loss, anemia and malaise. It is associated with false positive rheumatoid factor especially in the elderly. Positive rheumatoid factor does not make a diagnosis of rheumatoid arthritis.

[Q: 1455] OnExamination - Rheumatology

A 26-year-old male presents with a three month history of arthralgia, mouth ulceration and eye irritation. On examination he was afebrile, had some ulceration of the mouth, bilaterally swollen wrists and effusions with reduced range of movements of both knees.

Examination of the external genitalia revealed a scrotal ulcer. His investigations showed:

white cell count $12 \times 10^9/L$ (4-11)

C-reactive protein 120 mg/dl (<10)

rheumatoid factor negative

What is the most likely diagnosis?

- 1- Behcet's syndrome
- 2- Inflammatory bowel disease
- 3- Psoriatic arthritis
- 4- Reiter's syndrome
- 5- Sjogren's syndrome

Answer & Comments

Answer: 1- Behcet's syndrome

This man has Behcet's on the basis of his orogenital ulceration and oligoarthritis.

Behcet's syndrome is a multisystem disorder characterised by recurrent oral and genital ulceration, eye lesions (anterior or posterior uveitis or retinal vasculitis), skin lesions, (erythema nodosum, papulopustular lesions or folliculitis) and a positive pathergy test.

Other features include musculoskeletal involvement with a mono or oligoarthropathy, venous thromboembolism, neurological and gastrointestinal features.

Reiter's syndrome is a clinical triad of urethritis, conjunctivitis and arthritis after an infective dysentery.

Genital ulceration is not a feature of systemic lupus erythematosus, rheumatoid arthritis or Sjogren's syndrome.

[Q: 1456] OnExamination - Rheumatology

A 62-year-old man has back pain. An FBC shows a WBC count of $3.7 \times 10^9/L$ (4 - 11), hemoglobin 10.3 g/dL (14 - 18), MCV 85 fL, and platelet count $110 \times 10^9/L$ (150 - 400). His total serum protein is 85 g/l with an albumin of 41 g/l. A chest X-ray shows no abnormalities of heart or lung fields, but there are several lucencies in the vertebral bodies. You perform a sternal bone marrow

aspirate and get a dark red jelly-like material in the syringe.

The smear of the aspirate is most likely to show which of the following cell types as a prominent feature?

- 1- Fibroblasts
- 2- Giant cells
- 3- Metastatic renal cell carcinoma cells
- 4- Osteoblasts
- 5- Plasma cells

Answer & Comments

Answer: 5- Plasma cells

The patient has multiple myeloma. The bone marrow needle was in a lytic lesion filled with plasma cells. His serum globulin is high from a monoclonal gammopathy. Osteoblasts are most numerous in repair of bone, and callus is very firm. Fibroblasts produce collagen and are more numerous with the gross appearance of firm, white scar tissue. Giant cells may be seen in a variety of benign and malignant lesions of bone, but this does not explain the hypergammaglobulinemia. Osteolytic metastases of renal cell carcinoma could have the gross appearance described here, but would not account for hypergammaglobulinemia.

[Q: 1457] OnExamination - Rheumatology

An 81-year-old female presents with bilaterally painful knees. There was no history of gastrointestinal diseases. On examination she had crepitus but had a full range of movement of both knees.

Which one of the following is the most appropriate initial treatment for her painful knees?

- 1- Dihydrocodeine
- 2- Naproxen
- 3- Paracetamol

- 4- Celecoxib
- 5- Topical Diclofenac

Answer & Comments

Answer: 3- Paracetamol

This woman has osteoarthritis (OA) of the knees. The principle goal of systemic therapy is to provide the most effective pain relief with the least associated toxicity. Paracetamol is the initial therapy recommended for the treatment of OA of the hip and knee. Studies have shown that the short-term and long-term efficacy of paracetamol is comparable with that of ibuprofen and naproxen in people with knee osteoarthritis. Specific COX-2 inhibitors such as celecoxib have clinical benefit similar to that of traditional NSAIDs, but less GI toxicity although issues remain regarding their cardiovascular risk. They may be used in patients with GI intolerance of traditional NSAIDs.

[Q: 1458] OnExamination - Rheumatology

A previously well, 62-year-old hypertensive builder presents with pain, redness and swelling in the right knee, which started 12 hours ago. There is a family history of hypertension and joint problems.

What investigation is most important in identifying the cause of this patient's knee symptoms?

- 1- ESR
- 2- HLA status
- 3- Joint aspiration for microscopy and culture
- 4- Radiology
- 5- Serology

Answer & Comments

Answer: 3- Joint aspiration for microscopy and culture

This patient has an acute monoarthropathy with pain swelling and erythema of a single joint, this maybe septic arthritis he needs Joint aspiration for microscopy and culture to identify any infective organism so appropriate therapy can be guided. X ray is of no value in septic arthritis it only becomes abnormal following joint destruction.

[Q: 1459] OnExamination - Rheumatology

A 50-year-old Asian lady with severe rheumatoid arthritis has failed on most traditional DMARD treatments. She is currently on Methotrexate 20 mg weekly and for the last 6 months has been receiving regular infusions of the anti-TNF-alpha monoclonal antibody, Infliximab. Her joint disease has dramatically improved. She now presents with fevers, pleuritic chest pain and a large left sided pleural effusion, but little evidence of joint synovitis.

What is the most likely diagnosis?

- 1- Primary bronchial carcinoma
- 2- Pulmonary metastases
- 3- Pulmonary embolus
- 4- Rheumatoid related effusion
- 5- Tuberculosis

Answer & Comments

Answer: 5- Tuberculosis

The most likely answer is TB. All of the other answers are possible and need to be excluded. A rheumatoid effusion is unlikely when peripheral joint disease is so well controlled. Treatment with anti-TNF-alpha increases the risk of opportunistic infections and in particular, there is a significant increase in the risk of TB reactivation in conjunction with Infliximab.

[Q: 1460] OnExamination - Rheumatology

An otherwise healthy middle-aged man with no prior medical history has had increasing back pain and right hip pain for the past 10 years. The pain is worse at the end of the day. He has bony enlargement of the distal interphalangeal joints. A radiograph of the spine reveals the presence of prominent osteophytes involving the vertebral bodies. There is sclerosis with narrowing of the joint space at the right acetabulum seen on a radiograph of the pelvis.

Which of the following pathologic processes is most likely to be taking place in this patient?

- 1- Gout
- 2- Lyme disease
- 3- Osteoarthritis
- 4- Osteomyelitis
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 3- Osteoarthritis

Degenerative osteoarthritis is a common and progressive condition that becomes more frequent and symptomatic with aging. There is erosion and loss of articular cartilage. Rheumatoid arthritis typically involves small joints of the hands and feet most severely, and there is a destructive pannus that leads to marked joint deformity. A gouty arthritis is more likely to be accompanied by swelling, and deformity with joint destruction. The pain is not related to usage. Osteomyelitis represents an ongoing infection that produces marked bone deformity, not just joint narrowing. Lyme disease produces a chronic arthritis, but it is typically preceded by a deer tick bite with a skin lesion. It is much less common than osteoarthritis.

[Q: 1461] OnExamination -
Rheumatology

A man in his 20's begins to note persistent lower back pain and stiffness that diminishes with activity. In his 30's he also develops hip and shoulder arthritis, and in his 40's he is bothered by decreased lumbar spine mobility. He has no other major medical problems.

These findings are most typical for which of the following?

- 1- Ankylosing spondylitis
- 2- Calcium pyrophosphate dihydrate deposition disease
- 3- Lyme disease
- 4- Osteoarthritis
- 5- Rheumatoid arthritis

Answer & Comments

Answer: 1- Ankylosing spondylitis

He probably is also HLA B27 positive. The earlier in life the disease begins, the worse the prognosis. There is a progressive bony ankylosis, especially of spine. RA typically involves small joints. Osteoarthritis typically involves a single large joint. Calcium pyrophosphate dihydrate deposition disease (Pseudogout) is more typical of the elderly and occurs in acute attacks.

[Q: 1462] OnExamination -
Rheumatology

A 70-year-old man from Lancashire has noted increasing back and leg pain for several years. X-rays reveal bony sclerosis of the sacroiliac, lower vertebral, and upper tibial regions with cortical thickening, but without mass effect or significant bony destruction.

He also says his hat does not fit him anymore. He has greater difficulty hearing on the left. He has orthopnea and pedal edema.

Blood tests reveal an elevated serum alkaline phosphatase.

The most likely pathologic process that explains these findings is?

- 1- Decreased bone mass
- 2- Metastatic adenocarcinoma
- 3- Paget's disease of bone
- 4- Renal failure with renal osteodystrophy
- 5- Vitamin D deficiency

Answer & Comments

Answer: 3- Paget's disease of bone

This man has Paget's disease with high output cardiac failure and sensorineural deafness.

Renal osteodystrophy leads to lesions of osteitis fibrosa cystica admixed with osteomalacia, which are focal in nature. Metastatic disease to bone produces focal lesions, not more diffuse enlargement.

[Q: 1463] OnExamination -
Rheumatology

A 75-year-old female presents with hyperosmolar non-ketotic hyperglycaemia. She has a red, hot and swollen knee.

Which of the following is most useful in the diagnosis of the swollen knee joint?

- 1- ANA
- 2- CRP
- 3- Joint Aspiration
- 4- Orthopaedic referral for joint washout
- 5- Rheumatoid factor

Answer & Comments

Answer: 3- Joint Aspiration

Joint aspiration is the best option in this context. It is a simple procedure, with a high diagnostic yield. Sending the joint aspiration for M/C/S in a blood culture bottle may increase yield. The risk of introducing infection into the knee joint during simple

aspiration by non-experts is 1 in 10,000 procedures, so the procedure is safe.

[Q: 1464] OnExamination 2012 -
Nephrology

A 65-year-old with type 2 diabetes mellitus and a heavy smoking history is started on an angiotensin-converting enzyme inhibitor (ACEI) for high blood pressure.

His creatinine subsequently doubles from 100 $\mu\text{mol/l}$ to 200 $\mu\text{mol/l}$. His general practitioner is concerned about the possibility of renal artery stenosis.

Which of the following investigations would give the highest diagnostic yield for this condition?

- 1- CT abdomen
- 2- CT abdomen with contrast
- 3- Duplex ultrasonography
- 4- Magnetic resonance angiogram (MRA)
- 5- Plasma renin levels

Answer & Comments

Answer: 4- Magnetic resonance angiogram (MRA)

Renal artery stenosis is an important cause of hypertension to recognise.

A rise in creatinine of 15% from baseline is expected with commencement of an ACE-inhibitor.

In this vignette, the large rise in creatinine should warrant a search for renal artery stenosis given the likelihood of vascular disease.

Of the investigations listed, CT abdomen and CT abdomen with contrast should not be selected as CT imaging should be directed towards the aorta and not the abdomen (CT angiogram). In addition, the contrast could cause nephrotoxicity in the context of recent acute kidney injury.

Plasma renin levels can be measured but lack specificity.

Duplex ultrasonography is a common first line investigation but may not be diagnostic due to technical difficulties (obese patients, overlying bowel gas).

This leaves MRA as the top choice for investigating renal artery stenosis.

[Q: 1465] OnExamination 2012 -
Nephrology

According to the current classification, which of the following glomerular filtration rate (GFR) ranges in ml/min/1.73m^2 is representative of stage IV chronic kidney disease (CKD)?

- 1- 0 - 10
- 2- < 15
- 3- 15- 29
- 4- 30-59
- 5- 60-80

Answer & Comments

Answer: 3- 15- 29

This question tests knowledge of the classification of chronic kidney disease.

The table below lists stages of CKD and corresponding GFRs.

Options A, B, D and E are not reflective of stage IV chronic kidney disease and are therefore incorrect.

Stage	GFR ml/min/1.73m^2	Description
1	>90	Normal or increased GFR with other evidence of renal damage
2	60-89	Slight decrease in GFR, with other evidence of renal damage
3a	45-59	Moderate decrease in GFR, with or without other

		evidence of renal damage
3b	30-44	As above
4	15-29	Severe decrease in GFR, with or without other evidence of renal damage
5	<15	Established renal failure

The suffix (p) is used to denote the presence of proteinuria when staging CKD. These patients have a worse prognosis, which usually warrants secondary care follow-up.

[Q: 1466] OnExamination 2012 - Nephrology

A 28-year-old gentleman presents to hospital feeling unwell with a few days history of diarrhoea and abdominal pain. He reports having eaten at a 'burger van' a few days ago.

He has no previous hospitalisations. His initial laboratory tests show new onset renal impairment, anaemia and low platelets. His clotting is normal.

Which of the following pathogens is most likely to be responsible for this presentation?

- 1- Clostridium difficile
- 2- Escherichia coli
- 3- Enterococcus faecalis
- 4- Methicillin resistant Staphylococcus aureus (MRSA)
- 5- Streptococcus viridans

Answer & Comments

Answer: 2- Escherichia coli

Haemolytic uraemic syndrome is a syndrome composing of the triad of:

- Microangiopathic haemolytic anaemia
- Low platelets and
- Renal failure.

A number of pathogens are implicated including Escherichia coli, usually the O157:H7 subtype. This produces a verotoxin (also known as Shiga toxin) which binds to endothelial receptors, particularly in the renal, gastrointestinal and central nervous systems thereby causing the clinical symptoms. Thrombin and fibrin are deposited in the microvasculature, and cause haemolysis of circulating erythrocytes. Platelets are also sequestered.

The other pathogens which can cause HUS are Streptococcus pneumoniae, Shigella dysenteriae (type 1 and 3), HIV and Coxsackie virus.

This presentation is not classical of C. difficile as we are given no risk factors for this in the question stem so option A is incorrect.

Enterococcus faecalis is a bowel commensal which is unlikely to cause the degree of pathology described in this case so option C is incorrect.

There is no reason to suspect this gentleman is MRSA positive so option D is incorrect.

Streptococcus viridans is an upper respiratory tract and throat bacteria. This patient's presentation does not involve that organ system so option E is incorrect.

[Q: 1467] OnExamination 2012 - Nephrology

A 33-year-old male who is receiving regular haemodialysis is noted to have a plasma potassium of 6.9 mmol/L (3.5-4.9) before a dialysis session. Usually his potassium is less than 5.5 mmol/L.

Which food combination from the dietary history would be most likely to cause the high potassium concentration?

- 1- Cereal, toast, biscuits.
- 2- Filter coffee, tea, boiled potatoes.
- 3- Milk, butter, plain yoghurt

4- Milk, ham, chicken.

5- Tomato, potato crisps, banana.

Answer & Comments

Answer: 5- Tomato, potato crisps, banana.

In particular tomato and banana have high potassium content and patients should be advised to avoid such foods.

[Q: 1468] OnExamination 2012 - Nephrology

A 77-year-old chronic smoker presented with toe gangrene. He suffered from diabetes mellitus, and had a shrunken right kidney.

The patient had a serum creatinine level of 340 $\mu\text{mol/L}$ before this admission. Neither dorsalis pedis nor posterior tibial pulses were palpable. He was assessed by vascular surgeon, who recommended a magnetic resonance angiography (MRA) with gadolinium (in order to minimise the risk of contrast-induced nephropathy).

What opinion would you formulate?

- 1- Adequate hydration before gadolinium administration should solve the problem.
- 2- Diabetes mellitus is a contraindication for magnetic resonance angiography.
- 3- The magnetic resonance angiography with gadolinium is not recommended because it carries a risk of nephrogenic systemic fibrosis.
- 4- This patient should be administered N-acetylcysteine before receiving gadolinium.
- 5- This patient should be offered imaging with gadolinium because he had a high risk for iodinated radio contrast-induced nephropathy.

Answer & Comments

Answer: 3- The magnetic resonance angiography with gadolinium is not

recommended because it carries a risk of nephrogenic systemic fibrosis.

According to the latest guidelines, the need for a gadolinium-based contrast study should be carefully considered in any patient with chronic kidney disease stage 3 or greater.

Our patient, in other words, had a high risk for this condition of nephrogenic systemic fibrosis (NSF) with potentially fatal consequence. Because of a higher dose requirement of gadolinium in angiography, the odds of NSF are even higher for the patient.

This toxicity of gadolinium cannot be circumvented by hydration (option A) or N-acetylcysteine (option D); they are considered to be more appropriate for preventing radio contrast-induced nephropathy.

[Q: 1469] OnExamination 2012 - Nephrology

The kidney plays a number of important homeostatic and excretory roles. Despite being a small percentage of total body mass, it receives a significant proportion of the cardiac output.

Which of the following answers best estimates the proportion of cardiac output to the kidneys under normal physiological conditions?

- 1- 5%
- 2- 10%
- 3- 20%
- 4- 40%
- 5- 50%

Answer & Comments

Answer: 3- 20%

The kidney requires a significant proportion of the cardiac output to fulfil its functions.

The actual value of cardiac output can vary depending on different physiological states (for example, stress and hypovolaemia) but

approximately 20-25% of the cardiac output goes towards the kidney. Therefore 20% is correct.

The other options are incorrect estimates and should not be selected.

[Q: 1470] OnExamination 2012 - Nephrology

Which of the following lifestyle characteristics is associated with IgA nephropathy?

- 1- Alcohol excess
- 2- Cocaine use
- 3- High cholesterol
- 4- Obesity
- 5- Red meat intake

Answer & Comments

Answer: 1- Alcohol excess

IgA nephropathy is associated with a host of medical conditions.

Heavy alcohol use in the past is also associated with the disease.

There is no known significant association with cocaine use (option B), high cholesterol (option C), obesity (option D) or red meat intake (option E). These answers are therefore incorrect.

Reference:

Donadio JV, Grande JP. IgA nephropathy. *N Engl J Med.* 2002 Sep 5;347(10):738-48

[Q: 1471] OnExamination 2012 - Nephrology

A 66-year-old gentleman with a history of benign prostatic hyperplasia is admitted with a rise in creatinine from 100 μ l to 300 μ l from a routine blood test done in the community.

The admitting team requests an ultrasound of the kidneys which shows normal sized kidneys with no evidence of hydronephrosis.

Of the options below, select the most appropriate size of a normal adult kidney on ultrasound appearance (measured longitudinally).

- 1- 6 cm
- 2- 11 cm
- 3- 15 cm
- 4- 18 cm
- 5- 20 cm

Answer & Comments

Answer: 2- 11 cm

The normal adult kidney size on ultrasound is between 9-12 cm hence option B is correct.

Ultrasonography plays a crucial part in evaluating acute and chronic renal impairment. In this case of suspected prostatic obstruction it is important to exclude hydronephrosis.

In the adult population the usual range of kidney size measured longitudinally is between 9 cm-12 cm (hence option B is correct).

The other options, A, C, D and E fall out of this range and should not be selected.

Reference:

SA Emamian, MB Nielsen, JF Pedersen, and L Ytte *Kidney dimensions at sonography: correlation with age, sex, and habitus in 665 adult volunteers. Am. J. Roentgenol., Jan 1993; 160: 83 - 86.*

[Q: 1472] OnExamination 2012 - Nephrology

A 16-year-old female presents with a three year history of recurrent colicky loin pain. One year ago she passed a renal calculus.

Twenty four hour urine collection showed normal levels of calcium, phosphate and urate, but elevated levels of arginine, cystine, lysine and ornithine.

Which one of the following features is characteristic of this condition?

- 1- Accumulation of cystine in collecting system
- 2- Autosomal dominant inheritance
- 3- Cystine deposits within the cornea
- 4- Functional defects within the glomeruli
- 5- Radiolucent renal stone formation

Answer & Comments

Answer: 1- Accumulation of cystine in collecting system

This condition is typical of cystinuria/nephropathic cystinosis, an autosomal recessive genetic defect in membrane transport for cystine, lysine, ornithine and arginine in epithelial cells.

The disease is characterised by recurrent nephrolithiasis.

Radiolucent stones are not specific for this condition and may be seen with uric acid stones.

[Q: 1473] OnExamination 2012 - Nephrology

If a patient with chronic renal failure is treated with erythropoietin (EPO), *which of the following will be expected in this patient?*

- 1- Decreased pure red cell aplasia
- 2- Decreased risk of hypertension
- 3- Decreased risk of thrombosis
- 4- Increased well being
- 5- Reduced appetite

Answer & Comments

Answer: 4- Increased well being

Increased viscosity is seen in EPO therapy which may exacerbate hypertension and there is also increased risk of thrombosis.

Pure red cell aplasia is a rare unwanted effect due to stimulation of antibodies by administered EPO which cross reacts with the patient's endogenous EPO.

Improvement in haemoglobin level results in the increased well being and better appetite.

[Q: 1474] OnExamination 2012 - Nephrology

A 16-year-old girl presented with Henoch-Schönlein purpura and renal involvement.

What is the most likely outcome?

- 1- A high probability of relapse
- 2- Complete renal recovery
- 3- Persistent hypertension
- 4- Persistent proteinuria
- 5- Requirement for long term corticosteroids

Answer & Comments

Answer: 2- Complete renal recovery

Henoch-Schönlein purpura (HSP) is a self-limiting vasculitis which occurs in children and young adults.

It is characterised by non-thrombocytopenic purpura, arthralgia, abdominal pain and glomerular nephritis.

It is likely to be an immune complex disease involving immunoglobulin (Ig)A, but no treatment has proven efficacy.

The disease usually settles between four to six weeks without sequelae if kidney involvement is mild. However this condition can occasionally relapse.

[Q: 1475] OnExamination 2012 -
Nephrology

A 62-year-old man with a longstanding history of hypertension is seen in the outpatient clinic.

Investigations show:

Creatinine 280 $\mu\text{mol/L}$ (60-110)

Urinalysis: Blood ++

Protein 1.8 g/L

Ultrasound scan of kidneys: left kidney 8.5 cm; right kidney 8.9 cm.

What is the best investigation to diagnose the cause of his renal impairment?

- 1- Intravenous urogram (IVU)
- 2- Isotope renogram
- 3- Renal angiogram
- 4- Renal biopsy
- 5- Retrograde pyelogram

Answer & Comments

Answer: 4- Renal biopsy

This patient has a long history of hypertension, therefore it should have been appropriately controlled in the clinic.

The patient now presents with bilaterally shrunken kidneys, renal impairment and evidence of a glomerulonephritis.

In the presence of mild to moderate hypertension, proteinuria indicates either underlying renal disease or renovascular disease.

As this patient has blood and protein in the urine, on the background of impaired renal function and shrunken kidneys, the best investigation would be to perform a renal biopsy (assuming the hypertension was controlled). This would differentiate between renovascular disease and glomerulonephritis, which may be reversible.

If this patient had the above clinical findings without blood and protein in the urine, then the investigation of choice would be a renal angiogram, to diagnose renovascular disease.

[Q: 1476] OnExamination 2012 -
Nephrology

A 70-year-old female presents for investigation of fatigue and weight loss.

Investigations reveal:

Haemoglobin 9.0 g/dL (11.5-16.5)

White cell count $2.0 \times 10^9/\text{L}$ ($4-11 \times 10^9$)

Platelet count $250 \times 10^9/\text{L}$ ($150-400 \times 10^9$)

Total protein 74 g/L (61-76)

Albumin 28 g/L (37-49)

Urea 16 mmol/L (2.5-7.5)

Creatinine 250 $\mu\text{mol/L}$ (60-110)

Plasma glucose 6.5 mmol/L (3.0-6.0)

Urine dipstick analysis Protein + & blood +

Renal ultrasound Normal

Which one of the following investigations would be most appropriate for this patient?

- 1- 24 hour urinary protein estimation
- 2- Measurement of anti-glomerular basement membrane (anti-GBM) antibodies
- 3- Measurement of anti-neutrophil cytoplasmic antibodies (ANCA)
- 4- Plasma protein electrophoresis
- 5- Renal angiography

Answer & Comments

Answer: 4- Plasma protein electrophoresis

This patient may well have myeloma as reflected by the anaemia, leucopenia and elevated non-albumin protein concentration.

Thus plasma protein electrophoresis would be the investigation of choice in this patient.

[Q: 1477] OnExamination 2012 - Nephrology

A 65-year-old man is admitted with renal failure and is diagnosed with acute tubular necrosis (ATN).

Which of the following is least likely to be the cause of acute tubular necrosis?

- 1- Corticosteroid therapy
- 2- Hypertension
- 3- Hypovolaemia
- 4- Paracetamol poisoning
- 5- Rhabdomyolysis

Answer & Comments

Answer: 1- Corticosteroid therapy

Renal failure from ATN occurs in 25% of patients with severe hepatic damage.

Accelerated hypertension can cause small vessel obstruction with proliferative endarteritis of intralobular arteries and fibrinoid necrosis of afferent arterioles and glomerular capillary tuft.

Corticosteroid therapy has not been associated with ATN.

Other causes of ATN include:

- Hypotension
- Hepatic failure
- Eclampsia
- Drugs such as aminoglycosides, cephalosporins, cisplatin, amphotericin.

[Q: 1478] OnExamination 2012 - Nephrology

Which of the following concerning the pH of urine is correct?

- 1- Is a useful indicator of the acid/base balance of the blood
- 2- Rises on a vegetarian diet

- 3- Is determined by the concentration of ammonium
- 4- Is lower than 5.5 in renal tubular acidosis (RTA)
- 5- Would be above 7.0 after prolonged and severe vomiting

Answer & Comments

Answer: 2- Rises on a vegetarian diet

Urine pH is affected by diet, with vegetarians having more alkaline urine when compared with omnivores.

Animal proteins contained in meat, eggs and cheese are often converted into acidic products (for example, amino acids) during digestion, absorption or metabolism. This provides a daily increase in the body's acid content, which has to be excreted by the kidneys. For people eating a vegetarian diet, consumption of foods rich in citrate or carbonated drinks raise the urine pH.

Other situations can interfere with this balance, such as tubular function or bacterial infection, which often promotes an alkaline urine pH due to the presence of bacterial enzymes converting urea to ammonia.

Urine pH has variable effects upon stone formation. The solubility of uric acid is markedly decreased in an acidic solution so uric acid stones are more likely to form. However, calcium phosphate becomes less soluble at pH>6; hence calcium phosphate stones are more likely to form in an alkaline urine. Therefore dietary advice needs to be tailored to the clinical scenario.

C. Excretion of ammonium occurs when an acid urine is produced but the pH of urine is of course determined by the concentration of H⁺ ions.

D. Unable to lower the pH to less than 5.5 in type 1 RTA.

E. This would be expected in an attempt to compensate for the loss of acid; however when there is extracellular fluid depletion the retention of sodium takes priority.

Instead of bicarbonate being excreted it is reabsorbed in the proximal and distal nephron and this perpetuates the metabolic alkalosis until the fluid balance is restored with intravenous (IV) fluids.

Reference:

Grases F, Costa-Bauza A, Prieto RM. Renal lithiasis and nutrition. *Nutr J* 2006; 5:23. (free access through pubmed).

[Q: 1479] OnExamination 2012 - Nephrology

A 55-year-old homeless male was found stuporous and smelling of alcohol.

Observations in the emergency department reveal a core temperature of 34°C, a pulse of 50 bpm and blood pressure of 116/80 mmHg. Dipstick urine analysis shows blood +++.

Some of his investigations are listed:

Creatinine 320 µmol/l (60-110)

Gamma GT 40 U/l (10-40)

AST 550 U/l (1-40)

LDH 1500 U/l (10-250)

Urine microscopy no cells or organisms.

What is the most likely cause of the raised serum creatinine concentration?

- 1- Chronic renal failure
- 2- Dehydration
- 3- Hypothermia
- 4- Paracetamol poisoning
- 5- Rhabdomyolysis

Answer & Comments

Answer: 5- Rhabdomyolysis

The elevated serum creatinine is most likely due to rhabdomyolysis as the patient was

found unconscious, is hypothermic, and is likely to have sustained muscle injury.

The latter is confirmed by an elevated aspartate aminotransferase and lactate dehydrogenase (LDH) but the normal gamma-glutamyl transpeptidase (GGT) argues against these being released from the liver.

Rhabdomyolysis is strongly suggested by the fact that urinalysis is strongly positive for blood, whereas urine microscopy is negative for red blood cells.

The positive urinalysis is caused by myoglobin, a muscle protein released during muscle damage; this appears in the urine and can cause acute renal failure.

[Q: 1480] OnExamination 2012 - Nephrology

A 49-year-old smoker who had been diagnosed with diabetes mellitus two years ago was hospitalised because of a foot ulcer. Below knee amputation was performed because of necrotising fasciitis.

Pre-operatively, his serum creatinine measured 78 micromol/L. After recovery from the operation, a repeat creatinine showed a level of 54 micromol/L.

What is the most likely explanation for the decrease in serum creatinine level?

- 1- This is compatible with daily variation of creatinine level.
- 2- The kidney function did not improve but creatinine generation reduced after amputation.
- 3- The nephrologist started dialysis.
- 4- The kidney improved with resolved inflammation.
- 5- None of the above.

Answer & Comments

Answer: 2- The kidney function did not improve but creatinine generation reduced after amputation.

The use of serum creatinine to estimate the glomerular filtration rate can be misleading when the patient has abnormal muscle mass (such as leg amputation).

We assume an improvement of kidney function when there is a falling creatinine level; this statement holds true only in the absence of a large change in muscle mass (or meat intake).

The generation of creatinine is primarily determined by dietary intake and muscle mass, which probably accounts for the apparent 'improvement' in the creatinine level after an amputation (option D).

The option C should not be chosen because our question mentioned no clear indication for dialysis.

[Q: 1481] OnExamination 2012 - Nephrology

A 65-year-old woman with a history of recurrent urinary tract infections attends the Emergency department with loin pain and haematuria.

She is diagnosed with renal stones the composition of which is magnesium ammonium phosphate.

Which of the following organisms are likely to be implicated in her urinary infections?

- 1- Bacteroides fragilis
- 2- Enterococcus faecalis
- 3- Escherichia coli
- 4- Proteus mirabilis
- 5- Staphylococcus aureus

Answer & Comments

Answer: 4- Proteus mirabilis

Bacteroides fragilis (option A) and Enterococcus faecalis (option B) are bowel commensals but do not produce triple phosphate stones and so these answers are incorrect.

Escherichia coli is a common urinary tract pathogen but it is not associated with triple phosphate stones and so option C is wrong.

Staphylococcus aureus is rarely a urinary pathogen and is not associated with the production of triple phosphate stones. Option E is therefore incorrect.

Reference:

Moe OW. Kidney Stones: pathophysiology and medical management. Lancet. 2006 Jan 28;367(9507):333-44

[Q: 1482] OnExamination 2012 - Nephrology

A 78-year-old gentleman is admitted with diarrhoea, recent onset of atrial fibrillation, acute renal failure and abdominal pain.

Some of his laboratory parameters are shown below:

Sodium 146 mmol/L (135-145)

Potassium 3 mmol/L (3.5-5.0)

Bicarbonate 14 mmol/L (24-30)

Chloride 95 mmol/L (95-105)

Urea 30 mmol/L (2.5-6.5)

What is the anion gap of this patient?

- 1- 24
- 2- 30
- 3- 40
- 4- 45
- 5- 48

Answer & Comments

Answer: 3- 40

The anion gap is an estimate of the unmeasured anions in the serum and helps to differentiate the causes of metabolic acidosis.

This gentleman has a significantly raised anion gap possibly secondary to ischaemic bowel and lactic acid production.

Note that the serum urea is not involved in the calculation of the anion gap.

[Q: 1483] OnExamination 2012 - Nephrology

A 45-year-old gentleman presents with loin pain and haematuria and is found on ultrasound examination to have polycystic kidney disease.

Of note, his father died of a brain haemorrhage in his 50s. Genetic testing reveals that the patient has the PKD-1 gene mutation.

On which chromosome is this gene mutation found?

- 1- Chromosome 2
- 2- Chromosome 4
- 3- Chromosome 12
- 4- Chromosome 15
- 5- Chromosome 16

Answer & Comments

Answer: 5- Chromosome 16

The PKD-1 gene mutation is found on chromosome 16p and so option E is correct.

The PKD-2 gene mutation is found on chromosome 4 and gives rise to a milder phenotype. Option B is therefore incorrect.

The other chromosomes do not contain the PKD-1 gene and so options A, C and D are also incorrect.

Reference:

Wilson, PD. Polycystic Kidney Disease. *N Engl J Med.* 2004 Jan 8;350(2):151-64.

[Q: 1484] OnExamination 2012 - Nephrology

A 22-year-old woman who is taking long term doxycycline for severe acne comes to the clinic complaining of chronic thirst and polyuria. She has to pass urine two to three times per night, which is highly unusual for her.

There is no significant past medical history, and her only medication is the oral contraceptive pill.

On examination her lying BP is 136/80 mmHg, with a postural drop of 15 mmHg. Her BMI is 29. There were no other significant findings on physical examination.

Investigations show

Haemoglobin 13.8 g/dl(11.5-16.5)

White cells $6.3 \times 10^9/L$ (4-11)

Platelets $222 \times 10^9/L$ (150-400)

Sodium 141 mmol/l (135-146)

Potassium 4.8 mmol/l (3.5-5)

Creatinine 122 $\mu\text{mol/l}$ (79-118)

Urea 8.5 mmol/l (2.5-6.7)

Which of the following is the most appropriate treatment?

- 1- Discontinue the doxycycline
- 2- Fluid restrict her
- 3- Increase her oral fluid intake
- 4- Intranasal vasopressin
- 5- Oral bendroflumethiazide

Answer & Comments

Answer: 1- Discontinue the doxycycline

Tetracyclines are known to be a cause of nephrogenic diabetes insipidus, as are

Lithium

Certain anti-fungals

Certain anti-viral agents.

Whilst increasing her oral intake may relieve some of her symptoms of thirst, discontinuing the doxycycline is the only way to resolve both her thirst and her polyuria.

High dose intranasal vasopressin may relieve her symptoms but the most appropriate treatment is discontinuation of the tetracycline antibiotic.

[Q: 1485] OnExamination 2012 - Nephrology

A 65-year-old man presents with renal colic. The following day he passes a stone in his urine with analysis revealing that it is composed of uric acid.

Which one of the following is the most likely cause of this type of renal stone?

- 1- Allopurinol
- 2- Chronic renal failure
- 3- Primary hyperparathyroidism
- 4- Secondary polycythaemia
- 5- Thiazide diuretics

Answer & Comments

Answer: 5- Thiazide diuretics

Uric acid stones occur in 5-25% of all cases of nephrolithiasis. They are associated with hyperuricaemia and hyperuricosuria.

Predisposing factors for uric acid stone formation are:

Dehydration

High purine load (high protein diet)

As a primary factor in idiopathic gout

Associated with high cell turnover (for example, haematological malignancy).

Chronic renal failure is incorrect, as there is hyperuricaemia without hyperuricosuria.

Hyperparathyroidism is associated with calcium stones, not uric acid stones.

Primary polycythaemia would predispose to uric acid stone formation, whereas secondary polycythaemia does not.

Allopurinol is prescribed to treat gout and prevents uric acid formation, hence it reduces the frequency of uric acid stones.

The correct answer is thiazide diuretics. Thiazide diuretics cause hyperuricaemia and can predispose to hyperuricosuria and uric acid stone formation. Uric acid stones are also associated with underlying hypertension.

Thiazide diuretics are used to treat calcium stones as they increase the reabsorption of calcium from the proximal tubules, preventing hypercalciuria.

[Q: 1486] OnExamination 2012 - Nephrology

An 18-year-old female student attends the clinic as her father has just died with end-stage renal failure. He had been diagnosed with autosomal dominant polycystic kidney disease (ADPKD).

She wishes to know what investigations she requires.

Which of the following is an appropriate strategy in her management?

- 1- Geneticist referral
- 2- Glomerular filtration rate estimation
- 3- MRI brain
- 4- Ultrasound of the renal tract
- 5- Urine dipstick

Answer & Comments

Answer: 1- Geneticist referral

An ultrasound of the renal tract may not be appropriate at this patient's age, given that cysts may not become apparent until the age of 20.

Gross haematuria in ADPKD carries a poor prognosis however microscopic haematuria may be a complication.

Subarachnoid haemorrhage may be a cause of mortality in 9% of patients with ADPKD, though 8% of patients have an asymptomatic intracranial aneurysm; if the diagnosis is confirmed and there is a strong history of subarachnoid haemorrhage then an MRI would be indicated.

Genetic counselling is most appropriate in this context and genetic linkage analysis may be utilised.

[Q: 1487] OnExamination 2012 - Nephrology

A 79-year-old woman presents to the Emergency department following a mechanical fall, resulting in a left fractured neck of femur and a long-lie of 14 hours.

She is oliguric; her urine is dark in colour and shows 4+ to haemoglobin on urine dipstick.

Which of the following is consistent with a diagnosis of rhabdomyolysis?

- 1- Hypocalcaemia
- 2- Hypokalaemia
- 3- Hyponatraemia
- 4- Hypophosphataemia
- 5- Thrombocytopenia

Answer & Comments

Answer: 1- Hypocalcaemia

Her urine is dark due to myoglobin.

Dipstick will be positive for blood (a false positive). On microscopy no red cells are seen although there may be pigmented granular casts.

As serum calcium is bound to damaged muscle, rhabdomyolysis may result in hypocalcaemia. Around 20% of patients

become hypercalcaemic during recovery as this bound calcium is remobilised.

Hypokalaemia is not a typical feature of rhabdomyolysis. Instead, hyperkalaemia may be present and is a life-threatening complication of the syndrome. It occurs because potassium is released from necrotic myocytes and this is exacerbated in the context of acute kidney injury and metabolic acidosis.

However, severe hypokalaemia is considered as one of the causes of rhabdomyolysis.

Hyponatraemia is not a typical feature of rhabdomyolysis. Instead, sodium may be high if the patient is water deplete following trauma.

Hypophosphataemia is not a typical feature of rhabdomyolysis. Phosphate may instead be normal or high. However, severe hypophosphataemia is considered as one of the causes of rhabdomyolysis.

Thrombocytopenia would warrant consideration of an alternate diagnosis. It is not a typical feature of rhabdomyolysis.

[Q: 1488] OnExamination 2012 - Nephrology

A 60-year-old male presents with typical renal colic and one day later passes a small stone.

However, the original x ray of the abdomen revealed no obvious calculi.

What is the most likely composition of his calculus?

- 1- Calcium
- 2- Cystine
- 3- Oxalate
- 4- Phosphate
- 5- Uric acid

Answer & Comments

Answer: 5- Uric acid

The main constituent will be uric acid.

Major causes of stone formation:

Calcium stones (80%) - hypercalciuria (for example, primary hyperparathyroidism), hyperoxaluria (for example, XS intake, ileal disease and bypass)

Uric acid stones (10%) - high purine intake, high cell turnover

Cystine stones (2%) - cystinuria (AR defect in dibasic amino acid transporter)

Infection stones (5%) - chronic infection with urea splitting organisms causes stones made of magnesium ammonium phosphate and calcium phosphate

Other stones (3%) - include xanthine stones, rare renal chloride channel mutations can cause stone formation.

There appears to be a male predominance with a 2:1 ratio.

Calcium and infection stones are radio-opaque, cystine stones are weakly radio-opaque and urate stones are radiolucent.

[Q: 1489] OnExamination 2012 - Nephrology

A 42-year-old female is admitted following an overdose of diazepam and alcohol.

On examination she was unconscious with a core temperature of 34.5°C and a blood pressure of 110/80 mmHg.

Investigations reveal:

Creatinine 242 µmol/l (60-100)

AST 500 U/l (0-40)

Gamma GT 35 U/l (<50)

Urine microscopy No cells or organisms

Urine dipstick analysis blood+++

Ultrasound abdomen Normal

Which one of the following is the most likely cause of these findings?

- 1- Associated paracetamol poisoning
- 2- Chronic renal failure
- 3- Dehydration
- 4- Hypothermia
- 5- Rhabdomyolysis

Answer & Comments

Answer: 5- Rhabdomyolysis

This patient has taken an overdose of diazepam and has collapsed for an indeterminate period. She is now seen with renal impairment.

The features together with the elevated amino transferase (AST) (from muscle) suggest a diagnosis of rhabdomyolysis.

[Q: 1490] OnExamination 2012 - Nephrology

A 58-year-old man with longstanding hypertension was found to have a serum creatinine concentration of 275 µmol/L (60-110).

Urinalysis showed blood ++ and protein >1 g/L. Renal ultrasound showed the left kidney to be 9.2 cm long, the right to be 8.9 cm long (normal range for both kidneys 10-12 cm), and neither kidney was obstructed.

What is the best investigation to diagnose the cause of the renal impairment?

- 1- Intravenous urography
- 2- Isotope renography
- 3- Renal arteriography
- 4- Renal biopsy
- 5- Retrograde pyelography

Answer & Comments

Answer: 4- Renal biopsy

The presence of long standing hypertension, haematuria, significant non-nephrotic proteinuria is highly suspicious of glomerular

pathology, such as IgA nephropathy which is best characterised by a renal biopsy.

In the absence of obstruction on ultrasound, intravenous urography, retrograde pyelography, and isotope renography are not appropriate.

Renal size asymmetry in the presence of hypertension and renal impairment might prompt the search for renovascular disease. However in this case of kidneys are of similar and good size.

[Q: 1491] OnExamination 2012 - Nephrology

A 32-year-old woman with IgA nephropathy attended the clinic shortly after having a positive pregnancy test.

On physical examination, pulse rate was 60 / minute and blood pressure was 145/83 mmHg. Fundi and cardiac examinations were normal. There was no pedal oedema.

Urine protein measured 0.7 g daily. Her serum creatinine level was 60 µmol/L. Medications at that time were lisinopril and folic acid.

Which of the following recommendations is most appropriate?

- 1- Continue the folic acid and lisinopril
- 2- Continue the folic acid and lisinopril, but advise to stop lisinopril in the second half of pregnancy
- 3- Change lisinopril to losartan
- 4- Stop lisinopril
- 5- Target blood pressure of < 120/80 mmHg during pregnancy

Answer & Comments

Answer: 4- Stop lisinopril

Both ACE inhibitor and angiotensin-receptor blocker are contraindicated in pregnancy.

The use of ACE inhibitor during the second half of the pregnancy (option B) has been well

known to be associated with oligohydramnios (probably resulting from impaired fetal renal function) and neonatal anuria, and fetal death.

Although the old teaching might allow the use of lisinopril during the first trimester, an observational retrospective cohort study that included women with exposure to ACE inhibitors in the first trimester, as reported in 2006, raised the issue that the drug is associated with increased odds for cardiovascular defects and central nervous system defects.

By extrapolation, other blockers of renin-angiotensin system should also be switched to other class of antihypertensive drugs (before conception, if possible). In other words, options B and C are not appropriate.

Blood pressure goal during pregnancy, in general, is less aggressive (option E); a very tight blood pressure control is linked with an increased risk of fetal growth restriction. Pre-pregnancy doses of antihypertensive medications are not infrequently reduced, particularly in the second trimester.

[Q: 1492] OnExamination 2012 - Nephrology

A 20-year-old woman presents to the acute medical intake with lethargy and confusion.

On examination you note a purpuric rash covering the abdominal wall and thighs and a fever of 38°C. Investigations reveal a haemolytic anaemia, thrombocytopenia and acute kidney injury.

Which feature of the presentation makes the diagnosis of thrombotic thrombocytopenic purpura more likely than haemolytic uraemic syndrome?

- 1- Acute kidney injury
- 2- Confusion
- 3- Fever
- 4- Haemolytic anaemia

5- Thrombocytopenia

Answer & Comments

Answer: 2- Confusion

Thrombotic thrombocytopenic purpura (TTP) and haemolytic uraemic syndrome (HUS) have overlapping clinical features, with up to 60% of TTP patients missing at least one component of the classical pentad, and around 30% of HUS patients having neurological symptoms and fever.

Typically the degree of kidney injury is worse in patients with haemolytic uraemic syndrome.

Neurological symptoms are less common in haemolytic uraemic syndrome.

Acute kidney injury can be present in both conditions. It is typically more severe in haemolytic uraemic syndrome.

Neurological symptoms are much less common in patients presenting with haemolytic uraemic syndrome.

Fever can be present in both conditions.

Haemolytic anaemia can be present in both conditions.

Thrombocytopenia can be present in both conditions.

[Q: 1493] OnExamination 2012 - Nephrology

A 48-year-old woman patient presents to the medical intake with bilateral leg swelling.

Urine dipstick shows 4+ protein and serum albumin is 14 g/l (normal range 35-50 g/l). Renal function is within normal range.

Further urinalysis indicates nephrotic-range proteinuria. Further to this a renal biopsy is performed which shows thickened glomerular capillary loops.

Which of the following may be a cause for this presentation?

- 1- Candida spp.
- 2- Escherichia coli O157:H7
- 3- Helicobacter pylori
- 4- Hepatitis B
- 5- Mycoplasma spp.

Answer & Comments

Answer: 4- Hepatitis B

Secondary causes include:

Autoimmune disease

Infections

Drugs (captopril, gold, nonsteroidal anti-inflammatory drugs [NSAIDs]) or

Malignancy.

Infectious causes of membranous nephropathy include:

Hepatitis B

Hepatitis C

Syphilis

Malaria.

It can also be seen in HIV although this disease is more often associated with a focal glomerulosclerosis.

Candida spp. are not causes of membranous nephropathy.

Although related to haemolytic uraemic syndrome, Escherichia coli O157 is not a cause of membranous nephropathy.

H. pylori is related to peptic ulcer disease and is not a cause of membranous nephropathy.

Hepatitis B is a secondary cause of membranous nephropathy and patients with this syndrome should be tested.

Although a cause of atypical pneumonia, Mycoplasma spp. is not a cause of membranous nephropathy.

[Q: 1494] OnExamination 2012 -
Nephrology

You are asked to see an orthopaedic patient who developed renal failure after a two week course of gentamicin.

No features of hypovolaemia or sepsis are evident. You suspect a diagnosis of aminoglycoside-induced acute tubular necrosis.

Which of the following fit the diagnosis?

- 1- The patient's acute renal failure usually appears within two days of gentamicin
- 2- The patient is non-oliguric.
- 3- The urine microscopy shows active red cell casts.
- 4- We expect an irreversible renal failure.
- 5- All of above

Answer & Comments

Answer: 2- The patient is non-oliguric.

The reversible acute tubular necrosis after aminoglycoside reflects a concurrent impairment in the concentrating ability, and most patients are non-oliguric (option B).

We expect a diagnosis of acute renal failure beginning more than five days after the initiation of gentamicin; option A is incorrect.

The urine sediment (in contrast to the suggestion in option C) should either be benign or show granular or epithelial cell casts.

The doctor's role is to ensure no hypovolaemia, sepsis, or catabolic state, all of which will defer tubular regeneration (recovery).

Irreversible tubulointerstitial damage, however, is uncommon after discontinuing aminoglycoside.

[Q: 1495] OnExamination 2012 -
Nephrology

A 70-year-old woman was referred with a six-week history of painless macroscopic haematuria.

Her only medications were IM sodium aurothiomalate and oral ibuprofen, which she took for rheumatoid arthritis.

Investigations:

Serum creatinine 92 $\mu\text{mol/L}$ (60-110)

Urine dipstick blood ++++

Protein +

Abdominal plain x ray normal

Ultrasound kidneys and renal tract normal

Which one of the following is the best initial investigation?

- 1- Cystoscopy
- 2- Intravenous urogram (IVU)
- 3- Renal biopsy
- 4- Stop ibuprofen
- 5- Stop sodium aurothiomalate

Answer & Comments

Answer: 1- Cystoscopy

This lady has macroscopic haematuria and a trace of protein in the urine. She is taking ibuprofen and IM sodium aurothiomalate (gold). Her renal function is normal, as is the plain abdominal x ray and USS renal tract.

Ibuprofen is a common cause of interstitial nephritis, and this could present with painless haematuria.

Sodium aurothiomalate commonly causes trace proteinuria, and if present on its own is unimportant, but it can also cause membranous glomerulonephritis, which this lady could have.

However, the most important thing to exclude would be a bladder tumour initially before

embarking upon a renal biopsy. Therefore cystoscopy is the best initial investigation.

[Q: 1496] OnExamination 2012 - Nephrology

A 60-year old man with a history of non-small cell lung cancer was treated with a right lower lobectomy 12 months ago.

He had an abdominal CT scan one month ago which revealed hepatic mass lesions and hilar lymphadenopathy. He now presents with malaise and fatigue.

His results show:

Urinalysis Protein +++

24 hour urine protein 2.7 g/24hr

Serum urea 30 mmol/L (2.5-7.5)

Serum creatinine 450 µmol/L (60-110)

A renal biopsy shows focal deposition of IgG and C3 with a granular pattern.

What is the most likely diagnosis?

- 1- Goodpasture's syndrome
- 2- Membranous glomerulonephritis
- 3- Minimal change glomerulonephritis
- 4- Nodular glomerulosclerosis
- 5- Rapidly progressive glomerulonephritis

Answer & Comments

Answer: 2- Membranous glomerulonephritis

Membranous GN is associated with:

Malignancy

Elderly patients, male more than female

Medications: penicillamine, GOLD, captopril, and heavy metals: mercury and cadmium

Basement membrane thickening

Rheumatoid arthritis

Autoimmune disease: systemic lupus erythematosus (SLE), thyroid

Nephrotic syndrome is the main presentation

Hepatitis B

Odd infections - like syphilis, leprosy, HIV, schistosomiasis, malaria

Immune complex deposition with IgG and C3

Sickle cell disease.

Forty per cent remit without treatment, 30% develop endstage renal failure (ESRF).

[Q: 1497] OnExamination 2012 - Nephrology

A patient with end stage renal disease is receiving haemodialysis and erythropoietin.

Which of the following does erythropoietin therapy cause?

- 1- Benign intracranial hypertension
- 2- Hypotension
- 3- Myositis
- 4- Osteoporosis
- 5- Seizures

Answer & Comments

Answer: 5- Seizures

Hypertension is a frequent problem associated with erythropoietin and may induce seizures.

A particular symptom is the onset of sudden stabbing migraine-like headache and should raise awareness to the possibility of hypertensive crisis.

Other adverse effects of treatment with erythropoietin include:

Hyperkalaemia in uraemic patients

Increased packed cell volume (PCV) (especially with misuse by normal individuals)

Thrombocythaemia

Shunt thrombosis

Induction of iron deficiency
Skin rashes
Urticaria and
Flu-like illness.

[Q: 1498] OnExamination 2012 -
Nephrology

A 56-year-old gentleman established on peritoneal dialysis presents with abdominal pain, fever and cloudy drainage.

A diagnosis of peritoneal dialysis (PD) peritonitis is suspected.

Which of the following laboratory findings is most useful in establishing the diagnosis of PD peritonitis?

- 1- Doubling in serum C reactive protein (CRP)
- 2- Doubling in serum creatinine
- 3- Neutrophils consisting 10% of total white cell count (WCC) in PD fluid
- 4- Raised serum amylase
- 5- White cell count > 100/ mm³ in PD fluid sample

Answer & Comments

Answer: 5- White cell count > 100/mm³ in PD fluid sample

PD peritonitis is an important complication of peritoneal dialysis. The vignette describes a typical presentation.

A high suspicion for the diagnosis is required and empirical treatment is often started.

PD fluid WCC of greater than 100/mm³ is diagnostic of PD peritonitis and should be selected.

Raised serum CRP may be associated but is not necessarily diagnostic.

Likewise, doubling of serum creatinine may have multiple reasons and should not be selected.

Although amylase may be raised there can be other intra-abdominal causes.

A PD fluid neutrophil percentage of greater than 50% and not 10% is in keeping with PD peritonitis.

[Q: 1499] OnExamination 2012 -
Nephrology

A 46-year-old woman develops nephrotic syndrome and is awaiting further tests to establish the underlying aetiology.

In which circumstance would corticosteroids be most effective in reversing the nephrotic syndrome?

- 1- Membranous nephropathy
- 2- Mesangial IgA disease
- 3- Minimal change disease
- 4- Primary amyloidosis
- 5- Renal vein thrombosis

Answer & Comments

Answer: 3- Minimal change disease

Although there is no known effective treatment for IgA nephropathy, there have been reports of favourable response to long term corticosteroid therapy.

80% adults with minimal change glomerulonephritis (GN) will respond to steroids, although remissions can take up to 16 weeks.

Membranous GN does not respond to steroid treatment.

No specific treatment is available to cause regression of amyloid deposits.

[Q: 1500] OnExamination 2012 -
Nephrology

A 65-year-old gentleman with type 2 diabetes mellitus and hypertension is started on an ACE-inhibitor.

Which of the following is the most appropriate time period to check his creatinine and potassium after commencing the medication?

- 1- 24 hours after starting the medication
- 2- 48 hours after starting the medication
- 3- One to two weeks after starting the medication
- 4- Six hours after he takes the medication
- 5- Two months after starting the medication

Answer & Comments

Answer: 3- One to two weeks after starting the medication

Monitoring of renal function and potassium is important after commencement of an ACE inhibitor.

The optimum period to check this is one to two weeks after commencing the medication.

Six, 24 and 48 hours after starting the medication are too early to detect relevant changes. These answers should not be selected.

Two months after starting the medication is too late and should not be selected.

[Q: 1501] OnExamination 2012 - Nephrology

A 7-year-old boy is brought to the surgery by his mother. He has become unwell with severe diarrhoea which is now mixed with blood.

History of note is a visit to a model farm a few days earlier. He is nauseous, has a severe headache, and feels very unwell.

On examination he is pyrexial 38.2°C, his BP is 142/88 mmHg. He has a soft, diffusely tender abdomen.

Investigations show

Haemoglobin 9.2 g/dl(13.5-18)

White cell count 11.9 x 10⁹/L (4-10)

Platelets 76 x 10⁹/L (150-400)

Sodium 141 mmol/l (134-143)

Potassium 4.9 mmol/l (3.5-5)

Creatinine 192 µmol/l (60-120)

Bilirubin 92 µmol/l (<17)

Urine Blood ++

Protein ++

Which of the following is the most likely diagnosis?

- 1- Brucella infection
- 2- Campylobacter infection
- 3- Escherichia coli infection
- 4- Salmonella infection
- 5- Shigella infection

Answer & Comments

Answer: 3- Escherichia coli infection

The symptoms, signs and investigations are typical of Escherichia coli 157 infection, leading to haemolytic-uraemic syndrome (HUS).

The syndrome is characterised by:

Microangiopathic haemolytic anaemia

Thrombocytopenia

Acute renal failure.

The most likely route of infection is his trip to the model farm.

Unfortunately antibiotics confer no benefit and may increase the risk of neurological complications associated with HUS.

This patient should be referred urgently to the hospital for management of his fluid and electrolyte balance. Unfortunately fatality rates from HUS remain high, at between 5 and 10%.

[Q: 1502] OnExamination 2012 -
Nephrology

A 62-year-old man with a history of type 2 diabetes and renal failure comes to the Emergency department. He currently uses continuous ambulatory peritoneal dialysis, and has noticed an increase in his insulin requirements over the past 24 hours, dull abdominal pain, and now has a cloudy bag.

On examination he is pyrexial 37.8°C and looks unwell, his blood pressure is 142/88 mmHg, with a pulse of 90. His abdomen is generally tender to palpation.

Investigations show:

Haemoglobin 10.4 g/dl(13.5-18)

White cell count $13.6 \times 10^9/L$ (4-10)

Platelets $190 \times 10^9/L$ (150-400)

Sodium 137 mmol/l (134-143)

Potassium 5.3 mmol/l (3.5-5)

Creatinine 342 $\mu\text{mol/l}$ (60-120)

CRP 88(<10)

Peritoneal dialysis fluid >100 white cells/cm²

Which of the following organisms is most likely to be responsible?

- 1- C. albicans
- 2- S. aureus
- 3- S. faecalis
- 4- S. pyogenes
- 5- S. viridians

Answer & Comments

Answer: 2- S. aureus

Staphylococcus aureus, Staphylococcus epidermidis, Pseudomonas aeruginosa, and Escherichia coli are the commonest causes of peritonitis in peritoneal dialysis patients. Severe infections may be polymicrobial.

Treatment with intraperitoneal antibiotics is superior to intravenous antibiotics.

Persistent or recurrent peritonitis should prompt catheter removal.

[Q: 1503] OnExamination 2012 -
Nephrology

A 32-year-old female is diagnosed with Goodpasture's syndrome.

Which of the following therapies used in conjunction with plasmapheresis and corticosteroids would be expected to improve prognosis associated with the condition?

- 1- Azathioprine
- 2- Cyclophosphamide
- 3- Cyclosporin
- 4- Mycophenolate mofetil
- 5- Tacrolimus

Answer & Comments

Answer: 2- Cyclophosphamide

Studies reveal that without treatment mortality is as high as 90% in association with Goodpasture's.

However the prognosis is drastically improved with the removal of antigen through plasmapheresis, immunosuppression with corticosteroids and cyclophosphamide.

There are some studies revealing the potential of mycophenolate mofetil but the evidence is rather anecdotal.

[Q: 1504] OnExamination 2012 -
Nephrology

A 21-year-old female presents with joint pains and rash. On examination her blood pressure was 140/100 mmHg.

Investigations reveal:

Creatinine 90 $\mu\text{mol/l}$ (60-110)

Anti dsDNA antibodies Strongly positive(0-73)

24 hour urinary protein excretion 1.7 g(<0.2)

Renal biopsy Membranous nephropathy

What is the most appropriate next treatment for her nephropathy?

- 1- ACE inhibitor for blood pressure control
- 2- Cyclophosphamide
- 3- NSAIDs for arthralgia
- 4- Prednisolone for immunosuppression
- 5- Warfarin anticoagulation

Answer & Comments

Answer: 1- ACE inhibitor for blood pressure control

This patient has systemic lupus erythematosus with the disease affecting her kidneys.

The renal manifestations of SLE are highly variable, ranging from mild asymptomatic proteinuria and/or haematuria to rapidly progressive uraemia. The various presentations are difficult to classify into clinical syndromes and histological classes. Although lupus nephritis affects a third of patients early in the disease it is frequently unrecognised until nephritic and/or nephrotic syndrome with renal failure occur.

Histologically, a number of different types of renal disease are recognised in SLE, with immune-complex mediated glomerular disease being the most common. The up to date International Society of Nephrology/Renal Pathology Society 2003 classification divides these into six different patterns:

- I - minimal mesangial
- II - mesangial proliferative
- III - focal
- IV - diffuse
- V - membranous
- VI - advanced sclerosis

Patients with membranous lupus nephritis tend to present with nephrotic syndrome.

Microscopic haematuria and hypertension may also be seen. Biopsies show global or segmental subepithelial immune deposits or their morphologic sequelae, with or without mesangial alterations. It may occur in combination with class III or IV, in which case both are diagnosed. Progression is variable, and immunosuppression is not always needed. Cyclophosphamide, mycophenolate mofetil and azathioprine reduce mortality in proliferative forms of lupus glomerulonephritis, but the benefit is not clear in membranous forms.

More important to this patient's renal disease in this patient is aggressive blood pressure control. An angiotensin-converting enzyme (ACE) inhibitor would be first line, as it has been shown to reduce proteinuria independently of its effect on blood pressure.

Warfarin is not considered an appropriate treatment as this lady has not exhibited any prothrombotic tendencies.

Non-steroidal anti-inflammatory medication would treat her arthralgia but would have no effect on the prognosis of the disease.

Therefore the correct answer should be A, but immunosuppression may well be required to manage her extra-renal disease.

[Q: 1505] OnExamination 2012 - Nephrology

A 65-year-old female is referred with a long history of hypertension and episodic urinary tract infections.

Dipstick analysis of the urine shows blood +++ together with protein +++. Her urea is 20 mmol/L (2.5-7.5) and creatinine is 280 µmol/L (60-110).

An ultrasound of abdomen is requested and shows left and right kidneys of 9 cm in size (10-12) without evidence of obstruction.

Which one of the following is the best investigation to diagnose the cause of her renal failure?

- 1- Isotope renography
- 2- IV urography
- 3- Renal angiography
- 4- Renal biopsy
- 5- Retrograde pyelography

Answer & Comments

Answer: 4- Renal biopsy

This patient has impaired renal function with hypertension and significant proteinuria and haematuria (glomerulonephritis). The kidneys are smaller than expected with no evidence of obstruction.

Intravenous urography is not the investigation of choice in a patient with impaired renal function.

Isotope renography would provide information about the relative function of each kidney and would show areas of scarring due to renal stone disease, infection, or vascular disease. It would also exclude congenital malformations of the kidneys. Although useful it would not provide information on the cause of the haematuria and proteinuria.

Renal angiography is the gold standard for assessing renovascular disease. It is an invasive procedure with potential complications. This investigation would not exclude causes of proteinuria and haematuria.

Retrograde pyelography would be useful if there were any evidence of obstruction.

The best investigation is a renal biopsy. This would show any changes of glomerulonephritis along with renal scarring from longstanding hypertension or urinary tract infections.

[Q: 1506] OnExamination 2012 - Nephrology

A 60-year-old man wishes to act as a kidney donor to his 37-year-old wife.

She has end stage renal failure from polycystic kidney disease and is maintained on peritoneal dialysis.

The couple have two teenage daughters, neither of whom have renal cysts on recent ultrasound scans.

Which one of the following statements is correct?

- 1- Living related donation from one of the daughters would be preferable to donation from the husband
- 2- Living unrelated donation is not recommended in cases of inherited renal disease
- 3- The age difference between husband and wife is a relative contraindication to transplantation
- 4- The husband should not be accepted for kidney donation until all siblings have been considered
- 5- The results of living unrelated kidney donation are sufficiently poor that organ donation should not proceed

Answer & Comments

Answer: 4- The husband should not be accepted for kidney donation until all siblings have been considered

Providing there is a sibling who is proven not to have polycystic kidney disease, living related donation should be considered as this would ensure a better match and better graft survival. Siblings are close genetically, and therefore usually are a better match than spouses. The age difference is not, however, a contraindication to kidney donation.

Living unrelated kidney donation could also be considered, and is increasing in use in the UK.

In patients with polycystic kidney disease, or for other inherited diseases, a graft from an unrelated donor would not necessarily succumb to the same disease process. Results are usually excellent if a good match is found. This is usually organised by being on the transplant waiting list, therefore receiving a kidney from a family member is often quicker.

As polycystic kidney disease is inherited as an autosomal dominant condition, there is a significant (50%) risk that this lady's daughters have been affected. Obviously, if affected they are not suitable to act as renal transplant donors. Cysts usually develop during teenage years, so one cannot be confident a child has not been affected until they are at least 20: a normal ultrasound scan at 20 years of age means you can be 90% confident they are not affected, a normal scan at 30 increases the confidence level to 98%. Therefore this lady's siblings (who presumably are all adults) should be considered prior to her children, as those siblings affected by the condition should already be showing the phenotype.

[Q: 1507] OnExamination 2012 - Nephrology

A 43-year-old man has had vague malaise for three weeks.

Physical examination is normal, except for a blood pressure of 150/95 mmHg and pitting oedema of the legs to the knees.

Dipstick urinalysis shows no glucose, blood, ketones, nitrite, or urobilinogen, and the microscopic urinalysis reveals no RBC/hpf and only 1 WBC/hpf.

Additional laboratory testing reveals a 24 hour urine protein of 4.1 gm. His serum creatinine is 350 µmol/L (60-110) with urea of 30 mmol/L (2.5-7.5). His hepatitis B surface antigen is positive.

Which of the following conditions is he most likely to have?

1- Acute tubular necrosis

2- Diabetic nephropathy

3- Membranous glomerulonephritis

4- Post-streptococcal glomerulonephritis

5- Systemic lupus erythematosus

Answer & Comments

Answer: 3- Membranous glomerulonephritis

Membranous glomerulonephritis is an antibody mediated disease in which the immune complexes localise to the subepithelial aspect of the capillary loop. That is, between the outer aspect of the basement membrane and the podocyte (epithelial cell).

The immune complexes develop in situ or, less likely, by the deposition of circulating immune complexes. The antibody may bind to an intrinsic glomerular antigen or to an exogenous antigen planted on the capillary wall.

Approximately 25 to 30% of cases are secondary.

Common associations include:

Systemic lupus erythematosus and other connective tissue disorders

Drugs (gold, penicillamine, non-steroidal anti-inflammatory agents)

Hepatitis B, syphilis, quartan malaria, leprosy, schistosomiasis

Carcinoma, melanoma, leukaemia, non-Hodgkin's lymphomas.

Membranous glomerulonephritis is more common in adults and most patients are older than 30 years at diagnosis. Membranous glomerulonephritis accounts for 35-50% of cases of adult nephrotic syndrome.

Most patients present with heavy proteinuria, most commonly in the nephrotic range, that is insidious in onset. A few patients have accompanying microscopic haematuria.

[Q: 1508] OnExamination 2012 -
Nephrology

Which one of the following statements regarding renal function is correct?

- 1- A ten minute period of hyperventilation will normally be expected to lead to an increased rate of bicarbonate excretion in urine
- 2- Sodium reabsorption in the tubules is mainly controlled by aldosterone
- 3- The daily solute excretion will lie between 75 and 300 mosmol
- 4- The permeability of the proximal nephron to water increases in the presence of vasopressin
- 5- The rate of ammonium excretion in urine is inversely related to the rate of urinary hydrogen ion excretion

Answer & Comments

Answer: 1- A ten minute period of hyperventilation will normally be expected to lead to an increased rate of bicarbonate excretion in urine

Arginine vasopressin (AVP) acts on the collecting ducts increasing permeability to water.

The total solute excretion is approximately 700 mosmol/d.

Sodium reabsorption is mostly through active transport in the loop of Henle with only a modest reabsorption facilitated by aldosterone.

A ten minute period of hyperventilation would cause a respiratory alkalosis leading to an increased secretion of bicarbonate and retention of hydrogen ions.

The rate of ammonium excretion is proportional to the rate of hydrogen ion excretion.

[Q: 1509] OnExamination 2012 -
Nephrology

A 14-year-old boy visits his general practitioner complaining of feeling unwell, passing smoky dark urine and having swelling of his ankles.

Of note he reports a sore throat two weeks prior. His anti-streptolysin O titre is positive and his renal function is mildly impaired.

If this patient were to have a renal biopsy, *which of the following is the most likely finding?*

- 1- C4d staining positive
- 2- Effacement of podocytes on electron microscopy
- 3- Humps in the subepithelial space on electron microscopy
- 4- IgA deposition in the mesangium
- 5- Tram track pattern on light microscopy

Answer & Comments

Answer: 3- Humps in the subepithelial space on electron microscopy

Not all cases of post-streptococcal glomerulonephritis (GN) require a biopsy.

The characteristic electron microscopy findings are described in the correct option.

C4d staining positive is incorrect as this refers to detection of BK virus by the C4d stain.

Podocyte effacement is incorrect as this is diagnostic of minimal change disease.

IgA deposition in the mesangium is a biopsy finding in IgA nephropathy and so is incorrect.

The tram track appearance on light microscopy represents membranoproliferative glomerulonephritis and therefore should not be selected.

[Q: 1510] OnExamination 2012 -
Nephrology

Which of the following is true concerning metastatic calcification in chronic renal failure (CRF)?

- 1- Characteristically caused by calcium oxalate deposition
- 2- Decreased by vitamin D
- 3- Increased prevalence with time on haemodialysis
- 4- Rapidly reversed in all sites after parathyroidectomy
- 5- Unaffected by time on CAPD

Answer & Comments

Answer: 3- Increased prevalence with time on haemodialysis

CRF is associated with:

- Low serum calcium
- Hyperphosphataemia
- Increased parathyroid hormone (PTH)
- Reduced intestinal calcium absorption
- Raised alkaline phosphatase.

Parathyroidectomy improves extraskeletal calcification, but vascular calcification improves less than periarticular calcification.

Metastatic calcification is due mainly to calcium phosphate deposition, although CRF managed with dialysis is the commonest cause of secondary oxalosis (acute arthritis of small joints with digital calcific deposits).

Prolonged treatment with vitamin D (hence hypercalcaemia and hyperphosphataemia) increases extraskeletal calcification.

[Q: 1511] OnExamination 2012 -
Nephrology

A man developed *Helicobacter pylori* related duodenal ulcer after kidney transplantation.

He did not use aspirin; other concurrent medication included cyclosporine, prednisolone, azathioprine and amlodipine. The patient reported no known drug allergy.

What is the most reasonable eradication treatment regimen?

- 1- Bismuth + pantoprazole + metronidazole + tetracycline
- 2- Monotherapy with proton pump inhibitor
- 3- Pantoprazole + amoxicillin
- 4- Pantoprazole + amoxicillin + clarithromycin
- 5- Pantoprazole + metronidazole + clarithromycin

Answer & Comments

Answer: 1- Bismuth + pantoprazole + metronidazole + tetracycline

Clarithromycin is relatively contraindicated in kidney transplant recipients because of its interaction with cyclosporine.

Quadruple therapy containing a proton pump inhibitor, bismuth, metronidazole, and tetracycline (option A), has been shown in meta-analysis of comparative randomised controlled trials to achieve a similar eradication rate to clarithromycin-based triple therapy.

Monotherapies and dual therapies (options B and C) - usually a proton pump inhibitor and one antibiotic - have always had disappointing results in eradication of *Helicobacter pylori*.

Options D and E are theoretically effective in *H. pylori* infection, but clarithromycin interacts with cyclosporine. Being an enzyme inhibitor, this macrolide will result in an (undesirable) increase the blood level of cyclosporine.

Bismuth-based quadruple therapy (option A), as recommended in the Maastricht Consensus Report, is the main option for second-line therapy.

[Q: 1512] OnExamination 2012 -
Nephrology

A 72-year-old man with chronic kidney disease and atrial fibrillation was followed up in the outpatient clinic. The doctor requested an elective colonoscopy examination.

This patient has been taking dabigatran (an oral thrombin inhibitor). His estimated creatinine clearance was 30 ml/min/1.73 m².

How should we advise the patient before colonoscopy examination?

- 1- Continue the dabigatran
- 2- Stop dabigatran one to two days before colonoscopy
- 3- Stop dabigatran three to five days before colonoscopy
- 4- Stop dabigatran two weeks before colonoscopy
- 5- Check the clotting profile (prothrombin time) and decide the timing of stopping dabigatran before colonoscopy

Answer & Comments

Answer: 3- Stop dabigatran three to five days before colonoscopy

The drug dabigatran has a half life elimination of 12-14 hours in normal subjects; it lasts longer in patients with abnormal kidney function.

For patients with normal creatinine clearance, it is safe to discontinue the drug one to two days before colonoscopy procedure. For the patient in this scenario, it is better to stop the drug three to five days (option C) before the procedure. An even longer period might be considered for those undergoing major surgery, spinal puncture or placement of epidural catheter (in whom complete haemostasis is warranted).

Dabigatran is an oral anticoagulant that should be stopped before colonoscopy. The drug contributes to INR elevation but its effect

cannot be monitored in such manner. Similarly, use of aPTT can only provide an approximation of dabigatran's anticoagulant activity.

It should be noted that there is absence of antidote to reverse rapidly the anticoagulant effects of dabigatran in the case of life-threatening haemorrhage or surgery.

The time to discontinue the drug depends on the patient kidney function. In fact, it is recommended to evaluate renal function prior to (and during) therapy; there is indication-specific dose reduction protocol in patients with moderate renal impairment. Haemodialysis removes around 60% of the drug over two to three hours.

Clearance of the low molecular weight heparin is predominantly by renal route.

Please note that unfractionated heparin's half life is not affected by renal function; it is metabolised by hepatic and vascular endothelial heparinases.

[Q: 1513] OnExamination 2012 -
Nephrology

An elderly man was hospitalised because of viral encephalitis for which he received aciclovir intravenously.

There was a decline in the urine output five days later. A nephrologist in consultation suggested aciclovir-induced acute kidney injury.

Which of the following characteristics are compatible with the diagnosis?

- 1- This patient's renal function typically begins to deteriorate three weeks after aciclovir therapy.
- 2- The mechanism is tubular obstruction.
- 3- Renal ultrasound is expected to show hydronephrosis.
- 4- The urine microscopy does not add information

- 5- The patient should be asymptomatic apart from decrease in the urine output.

Answer & Comments

Answer: 2- The mechanism is tubular obstruction.

Intravenous doses of aciclovir, which has relatively low solubility, can lead to deposition of aciclovir crystals in the renal tubules, resulting in intratubular obstruction and foci of interstitial inflammation. This occurs more often in a dehydrated patient.

The decline in renal function is expected to begin shortly after aciclovir therapy (option A).

No hydronephrosis (option C) is seen because the obstruction is intratubular (and not ureteral).

However, patient will complain of flank or abdominal pain (presumably due to urinary tract obstruction); option E is therefore incorrect.

In some cases, birefringent needle-shaped aciclovir crystals (option D) can be seen in the patient's urine (particularly under polarised light).

This condition can be prevented by prior hydration and slow drug infusion.

[Q: 1514] OnExamination 2012 - Nephrology

A 51-year-old male comes to the surgery complaining of nausea and fatigue. You have previously seen him with symptoms of sinusitis, and a saddle nose deformity.

Most recently he has begun to complain of shortness of breath and a chronic cough.

On examination he is hypertensive at 160/92 mmHg. There are bilateral inspiratory crackles on auscultation of the chest.

Investigations show

Haemoglobin 11.8 g/dl (13.5-18)

White cell count $10.1 \times 10^9/L$ (4-10)

Platelets $182 \times 10^9/L$ (150-400)

Sodium 141 mmol/l (134-143)

Potassium 5.5 mmol/l (3.5-5)

Creatinine 230 $\mu\text{mol/l}$ (60-120)

ESR 72 (<10)

Urine Blood ++

Protein ++

Which of the following is the most likely diagnosis?

1- Goodpasture's syndrome

2- IgA nephropathy

3- Membranous nephropathy

4- Minimal change disease

5- Wegener's granulomatosis

Answer & Comments

Answer: 5- Wegener's granulomatosis

Wegener's granulomatosis is a multi-system disorder characterised by necrotising granulomas of medium and small blood vessels. Patients have constitutional symptoms such as fever, lethargy and weight loss.

Organ specific involvement includes:

Eyes

Upper airway

Lung

Renal

Nervous system

Skin

Joints

Men are affected slightly more often than women and typically present in the fourth or fifth decade. Patients often present with ocular or ENT symptoms for sometime before a diagnosis is made.

Autoimmune profile is likely to reveal a positive circulating anti-neutrophil cytoplasmic antibody (cANCA), and renal biopsy is the usual way to obtain a tissue diagnosis.

Treatment is with high dose steroids and cyclophosphamide, which has revolutionised this disease which is otherwise rapidly fatal.

[Q: 1515] OnExamination 2012 - Nephrology

A 17-year-old boy presented with a non-blanching rash over his legs, a swollen knee and painless frank haematuria.

Investigations revealed:

Serum Creatinine 210 $\mu\text{mol/L}$ (60-110)

Urine dipstick analysis: Blood+++

Urine dipstick analysis: Protein+

Urine culture Negative

Ultrasound of the kidneys Normal

Which glomerular abnormality is most likely to be present at renal biopsy?

- 1- Focal and segmental sclerosis
- 2- Foot process fusion
- 3- Linear deposition of IgG on the basement membrane
- 4- Mesangial deposition of IgA
- 5- Thickening of basement membranes

Answer & Comments

Answer: 4- Mesangial deposition of IgA

The likely diagnosis here is Henoch-Schönlein purpura (HSP).

HSP is an inflammatory disorder of unknown cause characterised by IgA-dominant immune complexes in smaller venules, capillaries and arterioles. It presents with purpura, arthritis (especially ankles and knees), abdominal pains, haematuria and proteinuria.

HSP is often associated with infectious agents such as group A Streptococci and Mycoplasma.

If there is progression to renal impairment then renal histopathology may include minimal change to severe glomerulonephritis that is indistinguishable from IgA nephropathy. However, mesangial Ig A deposits are the most typical features of HSP on renal biopsy.

[Q: 1516] OnExamination 2012 - Nephrology

A 45-year-old man with chronic renal failure presents to clinic complaining of increasing fatigue and weakness.

He receives three hours of haemodialysis, thrice weekly. His blood pressure is measured at 176/110 mmHg pre-dialysis and 166/95 mmHg post-dialysis.

Investigations pre-dialysis show:

Hb 9.5 g/d(13.0-18.0)

Potassium 6.9 mmol/l (3.5-4.9)

Creatinine 1567 $\mu\text{mol/l}$ (60-110)

Calcium(corrected) 2.1 mmol/l (2.2-2.6)

Which of the following options is most appropriate initial management for this patient?

- 1- Give alfacalcidol to correct hypocalcaemia
- 2- Increase the duration of each dialysis session
- 3- Reduce the potassium concentration in the dialysate
- 4- Start erythropoietin to increase haemoglobin level
- 5- Start ramipril to gain better control of his blood pressure

Answer & Comments

Answer: 2- Increase the duration of each dialysis session

Haemodialysis (HD) is a complex area and one which does not need to be completely understood by a general physician, or one early in the stages of training. This question deals with the complex concept of dialysis adequacy. The prime aim of long-term haemodialysis is to remove nitrogenous metabolic end-products, remove fluid and maintain electrolyte, fluid and acid-base equilibrium. Although toxin removal is critical, the removal of any particular toxin is a poor measure of haemodialysis adequacy because the removal rate depends on the pre-dialysis serum concentration. 'Clearance' is therefore used to indicate dialysis adequacy, and most commonly the clearance of urea is used.

Clearance is the ratio of removal rate to blood concentration. Removal rate can be measured instantaneously by sampling blood on either side of the dialyser and multiplying the difference by the inflow rate. Clearance is the removal rate divided by the inflow concentration. However, this only provides a measure of dialysis at one point in time. The adequacy of an entire haemodialysis session is best measured by the fall in solute concentration from before dialysis to after. This is calculated using complex equations and is expressed as Kt/V . The current recommendation for adequate dialysis for three treatments per week are a Kt/V of 1.2. The details are not needed for MRCP but are described in the references below for those who are interested.

A more crude assessment of the adequacy of dialysis can be obtained by noting the magnitude of the decrease in blood urea concentration (the 'urea reduction ratio').

In addition to assessing the reduction in urea, it is standard practice in the UK to take biochemical and haematological measurements before and after haemodialysis sessions at regular intervals (monthly in hospital HD patients and at least 3 monthly in home HD patients). Adequate HD is indicated by pre-dialysis serum bicarbonate levels of 18-

24mmol/l, potassium 4.0-6.0mmol/l, phosphate 1.1-1.7mmol/l, and calcium and albumin within normal range. It is also recommended that pre-dialysis haemoglobin concentration should be maintained between 11.0-12.0g/dl.

Cardiovascular morbidity and mortality remains very high in haemodialysis. Control of blood pressure is central to this, and improving adequacy of dialysis has proven value in overcoming this. Blood pressure varies significantly in HD patients depending on the time taken: pre-dialysis, post-dialysis or inter-dialysis. There is a lack of evidence regarding which value correlates best with long-term outcome. Hypertension pre-dialysis can be used a surrogate marker for inadequate ultrafiltration during haemodialysis. Available evidence indicates that control of a patient's fluid volume influences cardiovascular outcome. Volume and blood pressure are linked and it is therefore important to optimise ultrafiltration and dry weight to control blood pressure. All efforts should be taken to ensure haemodialysis patients are euvolaemic and normotensive, which include counselling on sodium and fluid restriction, adequate ultrafiltration and the use of medication. A high pre-dialysis or inter-dialysis blood pressure may be related to excessive sodium and water ingestion during the inter-dialysis period or a high dialysate sodium level, whereas a high post-dialysis blood pressure may reflect inadequate achievement of dry weight. Weight gain between dialyses of more than 4.8% is associated with increased mortality.

The combination of high pre- and post-dialysis blood pressure, and high pre-dialysis potassium, indicate that this patient is receiving inadequate dialysis. Both procedural issues (insufficient blood flow rate, dialysis time and frequency and needle size) and access issues should be addressed. If these fail to improve the situation a different dialysis

modality should be considered, such as more frequent or sustained haemodialysis. From the available options, increasing the duration of the dialysis session should be done initially.

His haemoglobin is also below the recommended level for a dialysis patient but you need to measure haematinics prior rather than jumping in with EPO treatment. Many haemodialysis patients are iron deplete, and in these cases intravenous iron is indicated rather than EPO in the first instance. Anti-hypertensive medication can be considered if adequate ultrafiltration fails to control this patient's blood pressure.

[Q: 1517] OnExamination 2012 - Nephrology

A 25-year-old woman who is 20 weeks pregnant is diagnosed with pyelonephritis.

She had suffered recurrent urinary infections since childhood and her family history reveals that her mother had a history of hypertension and had been told she had a kidney problem.

Examination was normal and urea and creatinine were both normal.

What is the most likely diagnosis?

- 1- Autosomal dominant polycystic kidney disease
- 2- Bladder outlet obstruction
- 3- Normal physiological urinary stasis of pregnancy
- 4- Reflux nephropathy
- 5- Renal stone disease

Answer & Comments

Answer: 4- Reflux nephropathy

This lady has had recurrent urinary tract infections since childhood and now presents with pyelonephritis. Pyelonephritis is an uncommon infection in pregnancy and requires aggressive treatment with antibiotics.

It is associated with preterm labour in 4% and may lead to fetal distress.

A. The answer is not ADPKD as symptoms do not tend to occur before the age of 40.

B. Bladder outlet obstruction should not occur in pregnancy and would cause hydronephrosis and worsening renal function.

C. Answer C is incorrect as this should not cause pyelonephritis.

E. Renal stone disease does predispose to developing urinary tract infections but is less likely than reflux nephropathy.

The correct answer is reflux nephropathy (D). This lady has a long history of urinary tract infections with probable underlying reflux scarring and this would predispose her to developing pyelonephritis in pregnancy.

[Q: 1518] OnExamination 2012 - Nephrology

A 68-year-old male is referred by his general practitioner with deteriorating hypertension and renal function.

Investigations show:

Serum Creatinine 250 $\mu\text{mol/L}$ (60-110)

Urinalysis + protein

Renal ultrasound scan:

left kidney 9 cm long

right kidney 7 cm, no obstruction (10-12 cm)

Which of the following would be the most appropriate investigation for this patient?

- 1- Intravenous renography
- 2- Isotope renography
- 3- MR angiography
- 4- Renal biopsy
- 5- Retrograde pyelography

Answer & Comments

Answer: 3- MR angiography

The diagnosis is likely to be atherosclerotic renal artery stenosis (RAS) as suggested by the asymmetric reduction in renal size, with mild proteinuria quite common in the condition.

Investigations include captopril renography, magnetic resonance (MR) angiography which is virtually as good as renal arteriography.

None of the other investigations are appropriate for RAS.

[Q: 1519] OnExamination 2012 - Nephrology

Which of the following is a feature of cystinuria?

- 1- A useful response to acidification of urine
- 2- Accumulation of cystine in the kidney
- 3- Autosomal dominant inheritance
- 4- Excessive urinary arginine excretion
- 5- Radiolucent urinary calculi

Answer & Comments

Answer: 4- Excessive urinary arginine excretion

Cystinuria is the commonest inborn error of amino acid transport.

Amino acids excreted in urine are cystine, ornithine, arginine and lysine (mnemonic - COAL).

The renal stones are radio-opaque due to the presence of sulphur.

It is inherited as an autosomal recessive condition.

Management includes alkalinisation along with high fluid intake (>4 L/day); d-penicillamine may also be used.

It is cystinosis that leads to accumulation of cystine in the kidney.

[Q: 1520] OnExamination 2012 - Nephrology

A 35-year-old gentleman presents with new onset renal failure and a non-blanching rash across his legs.

In addition, he describes a history of recurrent sinus infections and nose bleeds.

Which of the following tests are most likely to be diagnostic in this case?

- 1- ANA
- 2- C-ANCA
- 3- P-ANCA
- 4- Rheumatoid factor
- 5- Serum electrophoresis

Answer & Comments

Answer: 2- C-ANCA

Wegener's granulomatosis is disease of granulomatous inflammation involving the kidney, upper respiratory and sinus tracts. It is most often associated with the anti-cytoplasmic ANCA (c-ANCA) positivity.

Anti-nuclear antibody (option A) can be positive in wide range of connective tissue diseases and is not the best diagnostic test listed and so is incorrect.

P-ANCA is associated with microscopic polyangiitis and not Wegener's and so option C should not be selected.

Rheumatoid factor (option D) and serum electrophoresis for myeloma (option E) are not diagnostic tests in this case and so are incorrect.

[Q: 1521] OnExamination 2012 - Nephrology

Which of the following is correct in asymptomatic chronic renal failure (CRF)?

- 1- Decrease in blood pressure accompanied by increase in extracellular fluid

- 2- Increase serum (alkaline phosphatase) mainly due to liver isoenzyme
- 3- Serum ionised (calcium) is normal
- 4- Serum (phosphate) characteristically increased before GFR falls to 30 ml/min
- 5- There is increase in tubular excretion of urate

Answer & Comments

Answer: 3- Serum ionised (calcium) is normal

Urate retention is common feature in CRF.

Total serum (calcium) is reduced or at lower limits of normal but ionised (calcium) is normal unless steps are taken to treat acidosis actively, for example, with sodium bicarbonate.

Plasma phosphate is usually normal until CKD stage 5.

Hyperphosphataemia occurs when glomerular filtration rate (GFR) falls less than 30 ml/min.

Increased bone alkaline phosphatase reflects osteodystrophy.

Hypertension is due largely to salt and water retention, and also overactivity of renin angiotensin systems.

[Q: 1522] OnExamination 2012 - Nephrology

What is the most compatible joint finding of patients suffering from Henoch-Schönlein purpura?

- 1- Erosive arthropathy
- 2- Transient non-deforming oligoarthritis, mostly large joints of the legs
- 3- Symmetrical small hand joints
- 4- Preponderance of temporomandibular joint
- 5- Typical enthesitis

Answer & Comments

Answer: 2- Transient non-deforming oligoarthritis, mostly large joints of the legs

The arthritis of Henoch-Schönlein purpura is usually transient or migratory, involves one to four joints, and is non-deforming (option B). Typical sites are the lower extremity large joints (hips, knees, and ankles). Affected young children may refuse to walk.

Kidney manifestation occurs only in 10-50% of patients with the disease.

Purpura is the sine qua non of Henoch-Schönlein purpura. It may be difficult to diagnose this disease if the patient first presents with kidney involvement or joint manifestation.

Joint disease of Henoch-Schönlein purpura does not cause any chronic damage, as opposed to that of rheumatoid arthritis (hence incorrect for option A).

Symmetrical joint involvement of hands is atypical (hence incorrect option C).

Enthesitis (option E), inflammation of the region of attachment of tendons and ligaments, is a feature of ankylosing spondylitis and other spondyloarthritis.

[Q: 1523] OnExamination 2012 - Nephrology

You were asked to see a 50-year-old man who developed haemoptysis.

Further evaluation showed pulmonary infiltrates and his urine dipstick showed red cells and active urine sediments.

Which of the following evaluations would be most diagnostic?

- 1- A request for anti-glomerular basement membrane (anti-GBM) antibody and antineutrophil cytoplasmic antibody (ANCA).
- 2- A smoking history

- 3- Anti-Smith (Sm) antibodies
- 4- An ultrasound image of the kidneys
- 5- Fractional excretion of sodium

Answer & Comments

Answer: 1- A request for anti-glomerular basement membrane (anti-GBM) antibody and antineutrophil cytoplasmic antibody (ANCA).

Bleeding into alveolar space can be manifested as haemoptysis, and together with renal disease or glomerulonephritis, should prompt an evaluation for systemic vasculitis.

Pulmonary renal syndrome can result from Wegener's granulomatosis or ANCA-associated vasculitis. Goodpasture's syndrome (associated with anti-GBM) is another consideration.

Of interest, smoking (option B) appears to be of relevance in causing an epitope that incites an immune response (and thus alveolar damage and haemoptysis manifestation), but this piece of information would not be of the most diagnostic value.

Kidney biopsy, but not ultrasound alone (option D) is occasionally performed in patients with overt manifestations of renal disease (to look for a segmental necrotising lesion in this case).

[Q: 1524] OnExamination 2012 - Nephrology

A child-bearing woman asked you about the use of angiotensin converting enzyme (ACE) inhibitor in pregnancy.

Choose the best answer in response to her query.

- 1- ACE inhibitors are listed as FDA rating B; they can be used in pregnancy
- 2- ACE inhibitor should be changed to angiotensin receptor blocker before conception.

- 3- The drugs can be continued until second trimester because ACE inhibitor has not been shown to be teratogenic
- 4- ACE inhibitor should be withheld during the first trimester; it is otherwise safe in the second and third trimester.
- 5- ACE inhibitor should not be used during pregnancy.

Answer & Comments

Answer: 5- ACE inhibitor should not be used during pregnancy.

Contrary to previous teaching, a United States study (including 29,507 infants born between 1985 and 2000, 209 of whom were exposed to ACE inhibitors in the first trimester only) showed a significant increase in major (in particular, cardiovascular) congenital malformation. Option C is therefore incorrect.

Second and third trimester exposure to ACE inhibitors (option D) must be avoided because of the association with serious adverse fetal effects, notably oligohydramnios, in utero death, and neonatal anuria and renal failure.

The same probably applies to angiotensin receptor blocker (option B) and direct renin inhibitor (aliskiren).

[Q: 1525] OnExamination 2012 - Nephrology

A 72-year-old man presented with shortness of breath of two month duration. He has been treated for rheumatoid arthritis for the past 30 years.

On examination, his blood pressure was 190/110 mmHg, he had bilateral pitting ankle oedema, fourth heart sound, bilateral basal crackles and arthritic changes in the hands, wrists, ankles and left knee.

Basic investigations revealed the following results:

Sodium 128mmol/l137-144

Potassium 4.2 mmol/l/3.5-4.9

Urea 30 mmol/l/2.5-7.0

Creatinine 610 µmol/l/60-110

Glucose 7.8 mmol/l/3-6

Urinalysis protein +++

Ultrasound KUB: right and left kidneys 10cm and 10.6 cm respectively. No obstruction.

What is the cause of renal failure?

- 1- Acute glomerulonephritis
- 2- Amyloidosis
- 3- Analgesic nephropathy
- 4- Chronic pyelonephritis
- 5- Hypertensive nephropathy

Answer & Comments

Answer: 2- Amyloidosis

Acute glomerulonephritis presents more acutely and anuria is a prominent feature in chronic pyelonephritis.

Kidneys are small and scarred in chronic pyelonephritis.

[Q: 1526] OnExamination 2012 - Nephrology

Which of the following is the best estimate for total body requirement of sodium per day for a 70 kg adult male?

- 1- 30 mmol
- 2- 70 mmol
- 3- 120 mmol
- 4- 160 mmol
- 5- 180 mmol

Answer & Comments

Answer: 2- 70 mmol

Understanding sodium requirements is important especially when maintenance intravenous fluid prescriptions are required.

The average sodium requirement is 60-100 mmol per day (approximately 1 mmol/kg per day).

The best answer of those listed is 70 mmol. The other options fall out of this range and should not be selected.

[Q: 1527] OnExamination 2012 - Nephrology

A 65-year-old lady is evaluated for shortness of breath.

The attending clinician is concerned about a pulmonary embolism and proceeds with a CT pulmonary angiogram.

The radiologist is concerned about the risk of contrast induced nephropathy as the patient has some degree of existing renal impairment.

At what time period does contrast induced nephropathy classically peak?

- 1- 4-8 hours
- 2- 24-48 hours
- 3- 3-5 days
- 4- 14 days
- 5- 28 days

Answer & Comments

Answer: 3- 3-5 days

Studies have shown that contrast induced nephropathy is most likely to occur 48 to 72 hours after the administration of intravenous contrast hence option C is the best answer.

The other time periods stated are less likely therefore options A, B, D and E are incorrect.

Reference:

Barrett BJ, Parfrey PS. Clinical practice. Preventing nephropathy induced by contrast medium. *N Engl J Med.* 2006 Jan 26;354(4):379-86

[Q: 1528] OnExamination 2012 -
Nephrology

A 12-year-old boy presents to the surgery with peri-orbital and mild ankle oedema which has increased over the past few weeks.

Other history of note is a recent upper respiratory tract infection. He has been feeling increasingly tired and lethargic over the past few weeks.

On examination his BP is 138/72 mmHg. He has periorbital oedema and pitting ankle oedema.

Investigations show:

Haemoglobin 12.4 g/dl(13.5-18)

White cell count $7.8 \times 10^9/L$ (4-10)

Platelets $191 \times 10^9/L$ (150-400)

Sodium 141 mmol/l (134-143)

Potassium 4.6 mmol/l (3.5-5)

Creatinine 104 $\mu\text{mol/l}$ (60-120)

Serum albumin 28 g/l (35-50)

Urine Protein ++

Which of the following is the most likely cause?

- 1- IgA nephropathy
- 2- Alport's syndrome
- 3- Membranous nephropathy
- 4- Minimal change nephropathy
- 5- Post streptococcal glomerulonephritis

Answer & Comments

Answer: 4- Minimal change nephropathy

The history of periorbital oedema, normal blood pressure and creatinine, but proteinuria and low albumin is typical of minimal change disease.

The condition is much more common in this age range than membranous nephropathy, which also causes proteinuria.

The important point about making the diagnosis is that the condition responds to corticosteroid therapy in 90% or more of sufferers in childhood within two weeks, although treatment is usually continued for a period of eight weeks.

The lack of haematuria counts against post streptococcal glomerulonephritis, and IgA nephropathy.

Alport's syndrome is a familial nephritis associated with haematuria and progressive sensorineural hearing loss.

[Q: 1529] OnExamination 2012 -
Nephrology

A 32-year-old male with type 1 diabetes undergoes a 24 hour urine collection.

Which of the following urine albumin concentrations signify microalbuminuria?

- 1- 10 mg/day
- 2- 50 mg/day
- 3- 500 mg/day
- 4- 1 g/day
- 5- 3.5 g/day

Answer & Comments

Answer: 2- 50 mg/day

Microalbuminuria is defined as a urine albumin excretion of between 30-300 mg per 24 hours.

A concentration above 300 mg/24 hours signifies albuminuria and a concentration above 3.5 g/24 hours signifies overt proteinuria.

Microalbuminuria is not just an indicator of early renal involvement but it also identifies increased cardiovascular risk with an approximate twofold cardiovascular risk above the already increased risk in the diabetic population.

A useful surrogate of the total albumin excretion is the albumin: creatinine ratio.

The urinary albumin:creatinine ratio is measured using the first morning urine sample where practicable.

Microalbuminuria is indicated where there is an albumin:creatinine ratio > 2.5 mg/mmol (men) or 3.5 mg/mmol (women).

Proteinuria is indicated by a ratio of > 30 mg/mmol.

[Q: 1530] OnExamination 2012 - Nephrology

Which one of the following cytokines is strongly implicated in renal scarring?

- 1- Interferon alpha
- 2- Interleukin-10
- 3- Granulocyte colony stimulating factor
- 4- Transforming growth factor-beta
- 5- Tumour necrosis factor alpha

Answer & Comments

Answer: 4- Transforming growth factor-beta

Renal scarring is a serious complication of chronic pyelonephritis that occurs due to vesicoureteric reflux. It is mediated by cytokines, chemokines and their receptors, complement, adhesion molecules and extracellular matrix proteins. The cytokines which seem to play the largest role are interleukin (IL)-1beta, transforming growth factor (TGF)-beta and IL-3. TGF-beta in particular seems to be pro-fibrotic by recruiting fibroblasts, and a genotype where its production is limited has been shown to be less likely to develop renal scarring.

Interferon-alpha is produced by leucocytes, and is mainly involved in innate immune responses against viral infection. It is also made synthetically as medication, used for the treatment of hepatitis C, for example.

Interleukin-10 is an anti-inflammatory cytokine which acts to inhibit the synthesis of other cytokines. It also enhances B-cell survival, proliferation and antibody production.

Granulocyte colony-stimulating factor (G-CSF) is produced by a number of different tissues to stimulate the bone marrow to produce granulocytes, and release them into the blood. It also stimulates the survival, proliferation, differentiation and function of neutrophil precursors and mature neutrophils. It is used therapeutically in patients with neutropenia secondary to chemotherapy, particularly in cases of neutropenic sepsis.

Tumour necrosis factor (TNF)-alpha is one of the cytokines that can stimulate the acute phase reaction. The majority is produced by activated macrophages, and it acts to regulate immune cells, induce fever and sepsis, initiate cell apoptosis and inhibit tumourgenesis and viral replication.

[Q: 1531] OnExamination 2012 - Nephrology

A 30-year-old Caucasian man with HIV infection was found to have high blood pressure at 180/118 mmHg (high on several occasions). His father died of stroke at the age of 51.

Routine blood tests showed:

Sodium 145 mmol/l (135-145)

Potassium 3.4 mmol/l (3.5-5.1)

Creatinine 99 µmol/l (60-110)

Urea 4.9 mmol/l (2.9-9.0)

Urinanalysis No proteinuria

Plasma aldosterone 815 pmol/l (28-445)

Plasma renin 0.3 ng/ml/h(0.7-5)

Renal ultrasound Normal-sized kidneys

CD4 769 cells/ml

HIV RNA 4531 copies/ml

He was not on any antiretroviral therapy.

What is the most likely cause of his high arterial blood pressure?

- 1- Adult polycystic kidney
- 2- Conn's syndrome
- 3- Familial essential hypertension
- 4- HIV associated nephropathy
- 5- Non-Hodgkin's lymphoma involving kidneys

Answer & Comments

Answer: 2- Conn's syndrome

High aldosterone and low renin levels indicate primary hyperaldosteronism which accounts for up to 10% of all hypertensive patients. It is the most prevalent form of secondary hypertension.

Potassium level is often normal or the lower limit of normal and so hypokalaemia is not a prerequisite for diagnosis of Conn's syndrome.

Normal renal ultrasound makes adult polycystic kidney an unlikely cause of high blood pressure.

High aldosterone and low renin level is not seen in familial essential hypertension.

HIV associated nephropathy causes proteinuria.

Non-Hodgkin's lymphoma is often associated with low CD4 count.

Reference:

Hammer F, Stewart PM. Investigating hypertension in a young person. *BMJ* 2009; 338:885-6.

[Q: 1532] OnExamination 2012 - Nephrology

A 60-year-old woman is admitted with sudden onset of chest pain and is diagnosed with an acute myocardial infarction.

Her acute illness is complicated by low blood pressure and poor tissue perfusion for several days. Her serum lactate becomes elevated.

Her serum urea and creatinine are noted to be increasing.

	Day 1	Day 2	Day 3	Normal Range
Urea (mmol/L)	8	22	30	2.5-7.5 mmol/L
Creatinine (μmol/L)	116	140	200	60-110 μmol/L

Granular and hyaline casts are present on microscopic urinalysis.

What is the renal lesion that is most likely to be present in this situation?

- 1- Acute tubular necrosis
- 2- Minimal change disease
- 3- Nodular glomerulosclerosis
- 4- Pyelonephritis
- 5- Renal vein thrombosis

Answer & Comments

Answer: 1- Acute tubular necrosis

Ischaemia, typically in hypotensive hospitalised patients, is the most frequent antecedent to acute tubular necrosis.

Blood pressure should be maintained in cardiogenic shock with fluids and / or inotropic agents.

[Q: 1533] OnExamination 2012 - Nephrology

A 32-year-old woman is assessed at the antenatal clinic; she had no known medical disease prior to this pregnancy.

Which of the following scenarios is most compatible with chronic hypertension in pregnancy?

- 1- Blood pressure 135/92 mmHg at 28 weeks of gestation
- 2- Blood pressure 142/90 mmHg at 12 weeks of gestation

- 3- Documentation of proteinuria +++ by urine dipstick at 35 weeks of gestation.
- 4- Development of pre-eclampsia at 32 weeks.
- 5- Development of pre-eclampsia at 35 weeks.

Answer & Comments

Answer: 2- Blood pressure 142/90 mmHg at 12 weeks of gestation

Chronic hypertension in pregnancy is defined as blood pressure of at least 140 mmHg systolic or 90 mmHg diastolic before pregnancy, or for women who first present for care during pregnancy as in this case, before 20 weeks of gestation (option B).

Proteinuria at the third trimester (option C), if not present initially, favours the diagnosis of pre-eclampsia, instead of end-organ damage of chronic hypertension.

Women with chronic hypertension have an increased chance of pre-eclampsia and therefore pre-eclampsia (options D and E) per se does not exclude concurrent chronic hypertension. In fact, the condition of pre-eclampsia tends to develop at less than 34 weeks of gestation with chronic hypertension, earlier than is typical in women without antecedent hypertension.

Most women with chronic hypertension have a decrease in blood pressure during pregnancy. Their blood pressure falls toward the end of the first trimester. Still, chronic hypertension has to be diagnosed by first documentation of high blood pressure before 20 weeks of gestation (option B).

[Q: 1534] OnExamination 2012 - Nephrology

A 64-year old man is admitted to the Emergency department.

A recent discharge letter lists his co-morbidities as diet controlled diabetes

mellitus, chronic renal failure, angina, hypercholesterolaemia and hypertension.

He drinks between four to six units per day and is an ex-smoker with a 20 pack year history. You note blood tests from one month ago indicating a urea of 21 mmol/l and creatinine of 600 µmol/l.

He describes a sudden onset retrosternal pain that started 12 hours previously and is sharp and pleuritic.

On examination he is distressed but haemodynamically stable with a blood pressure of 133/57 mmHg, a heart rate of 78 and oxygen saturations of 99% on air. He is hunched forward as he feels this makes the pain better. He does not have a fistula in situ.

His heart sounds are dual with no murmurs and there are fine bibasal crepitations on respiratory examination. You can not discern a raised JVP but there is mild bilateral pitting oedema to mid calf.

An ECG reveals ST elevation in all leads. A chest radiograph indicates mild pulmonary oedema with no cardiomegaly. A full blood count is normal and electrolytes reveal a of 140 mmol/l, potassium of 5.2 mmol/l, urea of 44 mmol/l and creatinine of 746 µmol/l.

What is the most appropriate management for this patient?

- 1- CT angiogram
- 2- Haemodialysis
- 3- Omeprazole and oesophagogastroduodenoscopy
- 4- Primary coronary angioplasty
- 5- Treatment dose low molecular weight heparin and CT pulmonary angiogram

Answer & Comments

Answer: 2- Haemodialysis

The most likely diagnosis in the patient is uraemic pericarditis. We do not have enough history to discern how his kidney disease is

usually managed, but in the presence of pericarditis haemodialysis is required.

Other hard indications for acute haemodialysis are hyperkalaemia, acidosis and pulmonary oedema not responding to medical treatment.

Softer indications include other uraemic symptoms and anuria without any hard indications.

A. Aortic dissection is typically a sharp pain radiating to the back. The long history and ECG changes make this diagnosis unlikely.

B. Haemodialysis is appropriate in this patient with uraemic pericarditis.

C. Omeprazole and oesophagogastroduodenoscopy would be inappropriate as there is no suggestion of upper gastrointestinal pathology.

D. Primary coronary angioplasty would not be suitable in this patient as the ECG changes of global ST segment elevation relate better to pericarditis than acute coronary syndrome.

E. The history and ECG changes fit better with pericarditis than a pulmonary embolism; therefore treatment with dose low molecular weight heparin and CTPA would be inappropriate.

[Q: 1535] OnExamination 2012 - Nephrology

You are reviewing the guidelines for GP referral to the hospital service for possible renal artery stenosis because of an increase in the number of referrals over the past few months.

Which of the following correctly reflects a criterion for a patient who should be referred for further investigations?

- 1- BP>150/90 mmHg despite 2 anti-hypertensives
- 2- Fall of GFR>10% during first 2 months after starting an ACE inhibitor

3- Fall of GFR>15% over 12 months

4- Pulmonary oedema with reduced LV function

5- Unexplained hyperkalaemia with hypertension

Answer & Comments

Answer: 3- Fall of GFR>15% over 12 months

Criteria were published in 2009 for referral for suspected renovascular disease. These did include a fall of glomerular filtration rate (GFR) greater than 15% over 12 months against a background of renovascular disease. So option C is the correct answer.

Recurrent pulmonary oedema despite normal LV function is another referral criterion.

With respect to hypertension, lack of target achievement on three or more agents is a referral criterion, as is unexplained hypokalaemia in association with raised blood pressure.

GFR criteria after starting ACE inhibitor are a fall of greater than 15% during the first two months.

[Q: 1536] OnExamination 2012 - Nephrology

A 48-year-old teacher came to the nephrology clinic; he was found to have stage 3 chronic kidney disease during a health check. He wished to discuss future renal replacement therapy.

Which of the following is/are considered to be contraindication/s to peritoneal dialysis?

1. Presence of colostomy.
2. Heparin allergy.
3. Hepatitis B infection.
4. History of complex abdominal surgery with adhesion.

1- 1 and 4

- 2- 4 only
 3- 1, 3 and 4
 4- All of above
 5- None of above

Answer & Comments

Answer: 1- 1 and 4

Heparin anticoagulation (option 2), in contrast to extracorporeal haemodialysis therapy, is not needed for peritoneal dialysis.

Peritoneal dialysis makes use of a closed system (peritoneal cavity) to allow effective dialysis. Colostomy (option 1), or any other form of peritoneal cavity breach, is a contraindication to peritoneal dialysis.

Complex abdominal surgery and resultant extensive adhesion (option 4) damage the peritoneal membrane (peritoneal fibrosis) and lead to compartments within the peritoneum. This is now considered a relative contraindication to peritoneal dialysis.

Simple abdominal surgery, however, does not preclude peritoneal dialysis; examples include cholecystectomy, appendectomy or caesarean section.

[Q: 1537] OnExamination 2012 - Nephrology

A 40-year-old woman was referred for proteinuria (2.6 gram daily). Her serum creatinine level was 120 $\mu\text{mol/L}$. The referral letter mentioned a low serum complement C3 level.

With reference to the latter information, which of the following comments are relevant to her disease?

1. A history of infective endocarditis is of relevance.
2. A detailed medical history and physical examination to search for infection focus.
3. Diagnosis of myeloma should be suspected.

4. Hepatitis B and C serology should be sought.

5. Laboratory testing should include anti-nuclear antibody (ANA) and anti-double-stranded DNA antibody.

- 1- 1 and 4
 2- 2 only
 3- 3 and 4
 4- All except 3
 5- All of above

Answer & Comments

Answer: 4- All except 3

This is a case of hypocomplementaemia glomerular disease; differential diagnosis should include

Postinfectious glomerulonephritis
 (classically infective endocarditis)

Lupus nephritis

Membranoproliferative glomerulonephritis
 and

Mixed cryoglobulinaemia.

Her proteinuria points to glomerular pathology. Glomerular diseases with low complement levels narrow down the differential diagnosis.

Membranoproliferative glomerulonephritis is classically associated with decreased serum C3 (and a normal C4, indicating activation of the alternative pathway of complement). This indicates one form of chronic immune complex disease (see above for the common examples).

On the other hand, lupus nephritis is associated with activation of the classical pathway, and often associated with suppression of both C3 and C4. This is considered a correct answer although the question did not mention the C4 level.

The median age at diagnosis of multiple myeloma (option D) is 70 years, much older than this case.

Renal impairment is unrelated to immune complex; it occurs mostly as a result of direct tubular damage from excess protein load, dehydration, hypercalcaemia, and the use of nephrotoxic medications.

[Q: 1538] OnExamination 2012 - Nephrology

A 34-year-old lady is brought into the emergency department with protracted seizures. Laboratory studies reveal that her serum sodium is 114 mmol/litre.

The attending physicians wish to treat her with 'hypertonic saline' - stronger than the normal physiologic concentration.

What is deemed to be the physiologic concentration of saline?

- 1- 0.45%
- 2- 0.9%
- 3- 1.2%
- 4- 3%
- 5- 5%

Answer & Comments

Answer: 2- 0.9%

There are few indications for hypertonic saline. Ongoing seizures secondary to hyponatraemia is one such indication.

There are a number of hypertonic saline solution concentrations above the normal physiological value of 0.9%. The question asks for the physiological saline concentration and so 0.9% is correct.

Other answers listed are not physiologic and should not be selected.

Saline at 0.45% concentration is often termed half normal saline.

The remaining options represent hypertonic saline concentrations that can be administered.

[Q: 1539] OnExamination 2012 - Nephrology

Which of the listed medications has a thiazide-like action?

- 1- Acetazolamide
- 2- Bumetanide
- 3- Furosemide
- 4- Metolazone
- 5- Triamterene

Answer & Comments

Answer: 4- Metolazone

Metolazone is an example of a diuretic with a thiazide-like action.

Bumetanide and furosemide are loop diuretics, blocking reabsorption of sodium at the loop of Henle.

Acetazolamide is a carbonic anhydrase inhibitor and has no relation to thiazide-like action.

Triamterene is a potassium-sparing diuretic with no thiazide-like activity.

[Q: 1540] OnExamination 2012 - Nephrology

Antidiuretic hormone (ADH) plays a crucial homeostatic role in osmoregulation.

From where is antidiuretic hormone released?

- 1- Adrenal medulla
- 2- Anterior pituitary
- 3- Hypothalamus
- 4- Posterior pituitary
- 5- Right atrium

Answer & Comments

Answer: 4- Posterior pituitary

Antidiuretic hormone is synthesised in the hypothalamus and stored and released from the posterior pituitary.

The other locations described are incorrect and the other options should not be selected.

[Q: 1541] OnExamination 2012 - Nephrology

Antidiuretic hormone (ADH) plays an important role in osmoregulation.

Which of the mechanisms listed most accurately describes the action of ADH on the kidney?

- 1- Carbonic anhydrase inhibition in the proximal tubule
- 2- Constriction of the efferent arteriole of the glomerular apparatus more than the afferent
- 3- Downregulation of sodium channel in the thick ascending limb of the loop of Henle
- 4- Insertion of aquaporin channels in the collecting duct of the kidney
- 5- Insertion of ATP dependent sodium channels in the distal tubule

Answer & Comments

Answer: 4- Insertion of aquaporin channels in the collecting duct of the kidney

ADH plays a crucial role in maintaining the normal concentration of the serum.

Released by the posterior pituitary, it results in insertion of aquaporin channels in the collecting duct, allowing water reabsorption. ADH does not inhibit carbonic anhydrase, nor is it related to constriction of afferent or efferent arterioles.

ADH is not associated with action on the thick ascending limb of the loop of Henle, or in the distal tubule.

[Q: 1542] OnExamination 2012 - Nephrology

A 34-year-old female presents with shortness of breath.

She has been treated for asthma by her GP with an inhaled steroid, but the GP has documented an eosinophilia of $1.1 \times 10^9/L$ (14%) (normal $<0.1 \times 10^9/L$). She has been referred to the clinic because her GP found her creatinine to be $347 \mu\text{mol/L}$ (60-110).

Which of the following would support a diagnosis of Churg-Strauss syndrome?

- 1- Extravascular eosinophils on vascular biopsy
- 2- Fixed pulmonary infiltrates on chest radiographs
- 3- Peak flow $<150\text{ml/minute}$
- 4- Peripheral alveolar filling infiltrate predominantly in the upper lobes on a chest radiograph
- 5- Peripheral 'stocking' neuropathy

Answer & Comments

Answer: 1- Extravascular eosinophils on vascular biopsy

A diagnosis of Churg-Strauss syndrome requires four of the following features:

Asthma

Eosinophilia greater than 10%

Mononeuropathy or polyneuropathy

Paranasal sinus abnormality

Non-fixed pulmonary infiltrates visible on chest radiographs and

Blood vessels with extravascular eosinophils.

Peripheral alveolar filling infiltrate predominantly in the upper lobes on a chest

radiograph is typical of chronic eosinophilic pneumonia.

A peripheral 'stocking and glove' neuropathy is not typical of Churg-Strauss syndrome and is more common in type 2 diabetes.

[Q: 1543] OnExamination 2012 - Nephrology

A 75-year-old lady with metastatic lung small cell cancer is admitted with confusion, lethargy and hyponatraemia.

The admitting clinicians think that her presentation is compatible with syndrome of inappropriate diuretic hormone (SIADH).

Which of the following medications is appropriate treatment for this?

- 1- Demeclocycline
- 2- Furosemide
- 3- Intranasal desmopressin
- 4- Intravenous 5% dextrose
- 5- Spironolactone

Answer & Comments

Answer: 1- Demeclocycline

SIADH is the excess production of antidiuretic hormone (ADH) resulting in increased water retention at the distal tubules.

Among many causes, small cell cancer is associated with ADH secretion.

Demeclocycline will block the action of ADH on the distal tubules, thereby preventing water reabsorption.

Furosemide and spironolactone are diuretics and likely to lower serum sodium.

Intranasal desmopressin is equivalent to ADH and will worsen the situation, further lowering serum sodium.

Rehydration with 5% dextrose is likely to lower serum sodium more, so this should be avoided.

[Q: 1544] OnExamination 2012 - Nephrology

Urinary protein:creatinine ratio (PCR) represents a reliable way of quantifying proteinuria.

What PCR value in mg/mmol approximates to a 24 hour urine protein collection of 1g?

- 1- 10 mg/mmol
- 2- 100 mg/mmol
- 3- 500 mg/mmol
- 4- 750 mg/mmol
- 5- 1g/mmol

Answer & Comments

Answer: 2- 100 mg/mmol

Urinary protein creatinine ratio is a spot test that has been shown to approximate 24 hour urinary protein collection reliably. It avoids the cumbersome nature of collecting urine over 24 hours.

A 24 hour urinary protein collection of 1g is approximately equivalent to urinary PCR of 100 mg/mmol. The other values are incorrect and should not be selected.

[Q: 1545] OnExamination 2012 - Nephrology

During which age range is IgA nephropathy usually diagnosed?

- 1- 10-20 years
- 2- 20-40 years
- 3- 40-60 years
- 4- 60-70 years
- 5- 70 +

Answer & Comments

Answer: 2- 20-40 years

IgA nephropathy has a male preponderance and is commonly diagnosed in the age range of 20-40.

Options A, C, D and E which fall out of this age range are incorrect and should not be selected.

Reference:

Donadio JV, Grande JP. IgA nephropathy. *N Engl J Med*. 2002 Sep 5;347(10):738-48

[Q: 1546] OnExamination 2012 - Nephrology

A 24-year-old female presents with a 48 hour history of vomiting and epigastric pain. She has vomited over ten times in the last day.

There is no history of diarrhoea and the presumed diagnosis is viral gastroenteritis.

What is the most likely picture of her acid base status?

- 1- Mixed metabolic acidosis and respiratory alkalosis
- 2- Primary metabolic acidosis
- 3- Primary metabolic alkalosis
- 4- Primary respiratory acidosis
- 5- Primary respiratory alkalosis

Answer & Comments

Answer: 3- Primary metabolic alkalosis

Copious vomiting in this patient leads to loss of gastric contents which are predominantly acidic.

The resulting acid base picture is one of a metabolic alkalosis.

Options A and B are incorrect because the patient is in acid deficit rather than acid excess.

There is no primary respiratory pathology in the question and so options D and E are incorrect.

[Q: 1547] OnExamination 2012 - Nephrology

A 62-year-old woman presents with severe nausea and lethargy a few days after beginning diclofenac and amoxicillin from her GP for pain and a urinary tract infection. She has no past history of note apart from hypertension for which she takes ramipril, and she believes she injured her back lifting a wardrobe.

On examination her BP is 159/92 mmHg, she has bilateral crackles on auscultation of the chest, her pulse is 89 and regular. Abdominal examination is unremarkable. She has a widespread erythematous rash.

Investigations show

Hb 11.9 g/dl(13.5-18)

WCC $8.9 \times 10^9/L$

Eosinophilia(4-11)

PLT $203 \times 10^9/L$ (150-400)

Na 139 mmol/l (135-146)

K 6.1 mmol/l (3.5-5)

Cr 382 mmol/l (79-118)

Urine protein ++

Blood-

White cells-

Which of the following is the most likely diagnosis?

- 1- Acute tubular necrosis
- 2- Churg-Strauss syndrome
- 3- Interstitial nephritis
- 4- Membranous nephropathy
- 5- Pyelonephritis

Answer & Comments

Answer: 3- Interstitial nephritis

The rapid onset of renal failure, coupled with a rash and eosinophilia is highly suspicious of a diagnosis of interstitial nephritis as a result of exposure to non-steroidal or amoxicillin.

Whilst eosinophilia is not usually seen in interstitial nephritis as a result of NSAIDs, it is seen in penicillin-induced interstitial nephritis.

CT scanning and ultrasound are the main imaging modalities, with IVU being rarely used now. Renal biopsy is definitive in cases where the diagnosis is in doubt.

Resolution of renal failure usually begins after the causative agent is discontinued.

[Q: 1548] OnExamination 2012 - Nephrology

A 26-year-old man is referred to the clinic with microscopic haematuria. He also has hypertension, which the GP diagnosed as essential hypertension and commenced him on amlodipine 5 mg daily.

You understand on further questioning that his brother has haematuria and renal impairment and his father died of a stroke at the age of 42. On examination his blood pressure is 152/88 mmHg, he has bilateral ballotable kidneys.

Investigations show

Haemoglobin 13.4 g/dl(13.5-18)

White cell count $6.0 \times 10^9/L$ (4-10)

Platelets $242 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (134-143)

Potassium 4.7 mmol/l (3.5-5)

Creatinine 162 μ mol/l (60-120)

Urine blood ++

Protein -

Which of the following is the investigation most appropriate to elucidate the underlying diagnosis?

1- Contrast CT abdomen

2- Cystoscopy

3- Intravenous pyelogram (IVP)

4- Plain abdominal film

5- Ultrasound abdomen

Answer & Comments

Answer: 5- Ultrasound abdomen

The fact that his father and brother are both affected is suggestive of an autosomal dominant inherited disorder, probably autosomal dominant polycystic kidney disease (ADPKD).

Given that his father had a stroke at a young age, this raises the possibility of a berry aneurysm and subsequent subarachnoid haemorrhage.

ADPKD affects as many as 1 in 1000 individuals and is responsible for around 10% of the UK dialysis burden.

Polycystic liver disease is seen in 80% of patients but is usually asymptomatic. Abdominal ultrasound has a sensitivity approaching 100% for patients above 20 years of age.

Hypertension should be aggressively managed, with ACE inhibitors the therapy of choice.

[Q: 1549] OnExamination 2012 - Nephrology

A 54-year-old man with intermittent claudication was found to have renal impairment.

Investigations revealed:

Serum Creatinine 180 μ mol/l (60-100)

Urinalysis Protein++

Renal ultrasound revealed a right kidney of 7 cm and a left kidney of 10 cm (normal dimensions 10-14 cm).

Which investigation should be requested to establish a diagnosis?

- 1- Cystoscopy
- 2- Intravenous urography
- 3- Isotope renography
- 4- Renal arteriography
- 5- Renal biopsy

Answer & Comments

Answer: 4- Renal arteriography

This patient has renovascular disease with a right renal artery stenosis.

The gold standard for establishing a diagnosis of renal artery stenosis is renal arteriography and this is commonly performed with magnetic resonance angiography.

In one third of cases the disease is bilateral; 40% may have peripheral vascular disease and there may be proteinuria.

[Q: 1550] OnExamination 2012 - Nephrology

A 7-year-old boy is admitted with renal colic due to renal calculus.

His mother has a similar history of recurrent calculi.

What is the most likely explanation for recurrent renal calculi in both mother and child?

- 1- Cystinosis
- 2- Cystinuria
- 3- Hyperoxaluria
- 4- Idiopathic hypercalciuria
- 5- Urate uropathy

Answer & Comments

Answer: 4- Idiopathic hypercalciuria

Idiopathic hypercalciuria has a familial or sporadic pattern. In the familial pattern an autosomal dominant inheritance is present.

The type of the disease is identical in affected members of the same family and the typical presentation is of recurrent urinary calculi.

Cystinuria, cystinosis, urate uropathy and hyperoxaluria are autosomal recessive conditions.

[Q: 1551] OnExamination 2012 - Nephrology

A 30-year-old female presents with fevers and a three month history of malaise.

Results show:

Creatinine 250 $\mu\text{mol/L}$ (60-110)

Complement C3 23 mg/dL (65-190)

What is the likely diagnosis?

- 1- HIV nephropathy
- 2- Infective endocarditis
- 3- Membranous nephropathy
- 4- Microscopic polyangiitis
- 5- Minimal change nephropathy

Answer & Comments

Answer: 2- Infective endocarditis

Hypocomplementaemia is associated with either vasculitides such as systemic lupus erythematosus and cryoglobulinaemia but is also associated with a non-vasculitic process such as subacute bacterial endocarditis (SBE).

In this case with the three month history and fevers SBE is suggested.

In microscopic polyangiitis, which is classically small vessel, complement would be expected to be normal.

[Q: 1552] OnExamination 2012 -
Nephrology

A 43-year-old male is diagnosed with diabetic nephropathy. If this patient had type 1 diabetes his chances of progressing to end stage renal disease (ESRD) would be approximately 50%.

What percentage of patients with type 2 diabetes with diabetic nephropathy would be expected to progress to ESRD?

- 1- 15%
- 2- 30%
- 3- 45%
- 4- 50%
- 5- 55%

Answer & Comments

Answer: 1- 15%

Although the incidence of diabetic nephropathy is less in type 2 diabetics as approximately 90-95% of all diabetics are type 2s, the majority of patients with diabetic nephropathy are type 2 diabetics.

There are a number of stages in the development of nephropathy with glomerular hyperfiltration being an early feature. Nephropathy itself is signalled by the excretion of trace amounts of protein in the urine microalbuminuria.

The progression of the disease may be attenuated by stringent blood pressure control (with an angiotensin-converting enzyme inhibitor [ACEi]) and strict glycaemic control.

[Q: 1553] OnExamination 2012 -
Nephrology

A 17-year-old girl is admitted with a two day history of rigors due to a urinary tract infection.

On examination she appears unwell, has a body mass index (BMI) of 31 kg/m², a temperature of 39°C; examination is otherwise normal.

Initial biochemistry revealed:

Potassium 4 mmol/L(3.5-4.9)

Urea 7 mmol/L(2.5-7.5)

Glucose 33 mmol/L(3.0-6.0)

pH 7.3 (7.36-7.44)

Standard bicarbonate 14 mmol/L(20-28)

Base deficit -10 mmol/L

urinalysis negative for ketones

Which one of the following is the best initial treatment for her hyperglycaemia?

- 1- Metformin
- 2- Metformin plus gliclazide
- 3- Pioglitazone
- 4- Sliding scale IV insulin infusion
- 5- Subcutaneous insulin mixture

Answer & Comments

Answer: 4- Sliding scale IV insulin infusion

This patient has a metabolic acidosis with pH of 7.3 and low bicarbonate, this is most likely due to sepsis.

She is likely to have type 2 diabetes given the BMI with uncontrolled hyperglycaemia but is unlikely to have classical diabetic ketoacidosis because the urine is negative for ketones.

It is important that her glycaemia is controlled to promote recovery from the sepsis.

This is best achieved with intravenous insulin initially.

[Q: 1554] OnExamination 2012 -
Nephrology

A 25-year-old female wishes to start a family but she is concerned as her 50-year-old mother had adult polycystic kidney disease.

Examination reveals no specific abnormalities.

Which is the most appropriate initial screening test for polycystic kidney disease in this woman?

- 1- Genetic linkage analysis
- 2- Intravenous urogram
- 3- Isotope renography
- 4- Renal ultrasound
- 5- Urinalysis

Answer & Comments

Answer: 4- Renal ultrasound

The answer lies between renal ultrasound and genetic linkage analysis. Polycystic kidney disease is an autosomal dominant disorder. Mutations in at least three different genes can lead to autosomal dominant polycystic disease (APKD).

PKD-1 on chromosome 16: 85% of cases. Polycystin 1 is an integral membrane glycoprotein involved in cell/matrix interactions

PKD-2 on chromosome 4: 10% of cases. Polycystin 2 which may associate with polycystin 1 through a common signalling pathway

A third gene mutation is known but its exact chromosomal location is not.

Diagnosis is made by multiple bilateral renal cysts and a positive family history.

Genetic linkage studies: Can exclude or make the diagnosis in younger patients. Requires blood from at least two affected family members.

Ultrasonography:

In PKD 1 families, age related diagnostic criteria are used: two cysts in under 30 years age group.

At least two cysts in each kidney in 30-59 years. Four cysts in each kidney for over 60 years.

CT: More sensitive than USS and may aid in diagnosis in younger patients.

MR angiography: In patients with a family history of intracranial aneurysm - to screen for cerebral aneurysms.

[Q: 1555] OnExamination 2012 - Nephrology

You are called to the Emergency department to assess a 21-year-old student who has presented with bloody diarrhoea.

The diarrhoea started two weeks previously and was associated with increasing nausea and malaise and mild swelling of the lower limbs. She was having difficulty passing urine. She had eaten steak from the local butcher at a friend's barbeque the day before developing diarrhoea.

On examination she was pale with evidence of petechiae over her legs. Her face appeared puffy. Blood pressure was 160/95 mmHg. She was afebrile but had a tachycardia and crackles on inspiration at both lung bases. There was an old appendectomy scar in the right iliac fossa.

Investigations showed:

Haemoglobin 8.5 g/dl(11.5-16.5)

White cell count $13.2 \times 10^9/L$ (4-11)

Neutrophils $9.5 \times 10^9/L$ (1.5-7)

Platelets $35 \times 10^9/L$ (150-400)

PT 12s(11.5-15.5)

APTT 34 s(30-40)

Fibrinogen 4 g/l (1.8-5.4)

Serum Sodium 139 mmol/l (137-144)

Serum potassium 6.1 mmol/l (3.5-4.9)

Serum urea 40 mmol/l (2.5-7.5)

Serum creatinine 411 $\mu\text{mol/l}$ (60-110)

Serum albumin 27 g/l (37-49)

Dipstick urine Blood ++ Protein +

What is the single most important next investigation to determine the diagnosis?

- 1- ASO titres
- 2- Blood film analysis
- 3- Renal tract ultrasound
- 4- Transthoracic echocardiogram
- 5- Urine microscopy

Answer & Comments

Answer: 2- Blood film analysis

This patient has haemolytic uraemic syndrome (HUS).

It typically presents with a triad of:

- Acute renal failure (ARF)
- Microangiopathic haemolytic anaemia
- Thrombocytopenia with normal clotting.

HUS is a complication of infection with verocytotoxin producing *Escherichia coli* usually of the serotype 0157:H7.

Toxins produced in the intestine enter the blood and bind to endothelial cells in target organs. Endothelial cell damage leads to platelet and fibrin deposition with resultant fragmentation of circulating red blood cells and microvascular occlusion.

The syndrome has also been reported after infections with coxsackie, echovirus and Shigella.

HUS is characterised by the sudden onset of haemolytic anaemia with fragmentation of red blood cells, thrombocytopenia and acute renal failure after a prodromal illness of acute gastroenteritis often with bloody diarrhoea.

Clinical signs include increasing pallor, haematuria, oliguria and purpura. Jaundice is occasionally seen. Hypertension may be present.

Typical results show an anaemia, thrombocytopenia, and often a neutrophilia. Blood film shows fragmented erythrocytes.

Urea and electrolytes are typical of acute renal failure. There is normal coagulation and fibrinogen.

Neurological complications include:

Stroke, seizure and coma occur in 25% of patients

Rarely pancreatitis

Pleural and pericardial effusions.

Approximately 5% of patients will develop end stage renal failure.

Long term renal sequelae range from proteinuria to chronic renal failure.

Therapy is supportive with:

- Correction of anaemia
- Correction of uraemia by early dialysis
- Strict fluid balance
- Treatment of hypertension.

Major differential diagnosis is:

Sepsis with DIC - presents with abnormalities of clotting parameters.

TTP - thrombotic thrombocytopenic purpura presents with microangiopathic haemolytic anaemia, thrombocytopenic purpura, neurologic abnormalities, fever, and renal disease.

Renal abnormalities tend to be more severe in HUS.

Although once considered variants of a single syndrome, recent evidence suggests that the pathogenesis of TTP and HUS is different. Patients with TTP lack a plasma protease that is responsible for the breakdown of von Willebrand factor (vWF) multimers and these accumulate in the plasma. The activity of this protease is normal in patients with HUS.

Until the test for vWF protease activity becomes available, differentiation between HUS and TTP is based on the presence of central nervous system involvement in TTP and the more severe renal involvement in HUS.

In HUS 90% of patients are children and a history of prodromal diarrhoeal illness is more common.

The therapy of choice for TTP is plasma exchange with fresh frozen plasma.

[Q: 1556] OnExamination 2012 - Nephrology

A 23-year-old female presents at 16 weeks into her first pregnancy with a blood pressure of 144/96 mmHg. A 24 hour urine collection reveals a protein excretion of 0.7 g/d (<0.2)

What is the most likely explanation for these findings?

- 1- Essential hypertension
- 2- Gestational hypertension
- 3- Normal changes of pregnancy
- 4- Pre-eclampsia
- 5- Secondary hypertension

Answer & Comments

Answer: 5- Secondary hypertension

This pregnant woman has hypertension and proteinuria (as defined by a blood pressure above 140/90 mmHg and proteinuria above 0.3 g/d). It would not be regarded as normal to have this high a blood pressure or protein content of urine.

Hypertensive disorders during pregnancy occur in women with pre-existing primary or secondary hypertension, and in women who develop new-onset hypertension (defined as those cases occurring after 20 weeks).

All patients who have hypertension during pregnancy are at increased risk of eclampsia.

Although the rate of this is decreasing, hypertension in pregnancy remains one of the leading causes of maternal death. In addition it can lead to stillbirth, preterm birth and small for gestational age babies.

In pregnancy chronic hypertension is defined as hypertension that is present at the booking visit or before 20 weeks, or if the woman is already taking antihypertensive medication when she conceives. It can be primary or secondary in aetiology.

Gestational hypertension is new hypertension which presents after 20 weeks without significant proteinuria.

Pre-eclampsia is new hypertension presenting after 20 weeks with significant proteinuria. Severe pre-eclampsia is pre-eclampsia with severe hypertension (>160/110) and/or with symptoms (headache, visual disturbance, abdominal pain, vomiting, breathlessness and oedema), and/or biochemical and haematological impairment.

The presence of significant proteinuria in chronic hypertension should alert you to the suspect underlying renal disease, especially in a young patient. Significant proteinuria is defined as a urinary protein:creatinine ratio greater than 30mg/mmol or a 24-hour urine collection or more than 300mg protein. In pregnancy it only indicates pre-eclampsia if it develops after 20 weeks gestation.

Management of chronic hypertension in pregnancy involves determining the cause (if you suspect it to be secondary), restricting dietary sodium, regular antenatal check-ups, and anti-hypertensive treatment. Blood pressure should be kept less than 150/100mmHg, unless there is evidence of target-organ damage in which case the blood pressure should be kept less than 140/90mmHg.

Patients with chronic hypertension are at increased risk of developing pre-eclampsia and are therefore prescribed 75mg of aspirin

daily from 12 weeks, which is believed to reduce the risk. ACE inhibitors and angiotensin-II receptor blockers are avoided due to their increased risk of congenital malformations. In general treatment should be overseen by an obstetrician if there is primary hypertension, and a renal physician or endocrinologist if secondary hypertension is suspected.

[Q: 1557] OnExamination 2012 - Nephrology

A 72-year-old male presented to his GP with depression after the death of his wife.

His notes also reveal that he has a two year history of urinary hesitancy and poor stream. His GP prescribed him some medication and the following day he developed acute urinary retention.

Which of the following drugs is most likely to have precipitated the urinary retention?

- 1- Amitriptyline
- 2- Diazepam
- 3- Fluoxetine
- 4- Venlafaxine
- 5- Zopiclone

Answer & Comments

Answer: 1- Amitriptyline

Amitriptyline has anticholinergic effects, being associated with tachycardia, dry mouth and urinary retention.

These features are not typical of selective serotonin reuptake inhibitors (SSRIs) such as venlafaxine and fluoxetine, with urinary retention and dry mouth rarely reported.

Diazepam, a benzodiazepine does not have anticholinergic effects.

Zopiclone is a benzodiazepine-like agent whose side effects include drowsiness.

[Q: 1558] OnExamination 2012 - Nephrology

A 45-year-old man had recurrent nephrolithiasis.

Renal function tests and serum calcium measurements were normal.

A 24 hour urine collection revealed:

Volume 3L

Calcium 15 mmol/24 hours (2.5-7.5)

Oxalate 200 mmol/24 hours (90-450)

Uric acid 3 mmol/24 hours (1.48-4.45)

Citrate 2mmol/24hours (0.3-3.4)

What is the most useful therapy to reduce stone formation?

- 1- Allopurinol
- 2- Dietary calcium restriction
- 3- Penicillamine
- 4- Potassium citrate
- 5- Thiazide diuretic

Answer & Comments

Answer: 5- Thiazide diuretic

This patient has hypercalciuria and thiazide diuretics can decrease urinary excretion of calcium and possibly oxalate.

Dietary calcium restriction will not limit calciuria, given the large amount of calcium that can be mobilised from bone.

The lack of hyperuricosuria and hypocitraturia excludes the other treatments offered.

[Q: 1559] OnExamination 2012 - Nephrology

A 30-year-old woman presented with hypertension (160/110 mmHg), elevated titres of antibodies to double-stranded DNA, and proteinuria (1g per 24 hours).

A renal biopsy demonstrated WHO class II lupus nephritis (mesangial disease).

What is the most appropriate single treatment for this patient?

- 1- Antihypertensive medication
- 2- High-dose corticosteroids
- 3- Intravenous cyclophosphamide
- 4- Oral cyclophosphamide
- 5- Plasma exchange

Answer & Comments

Answer: 1- Antihypertensive medication

There is good evidence that immunosuppression could alter outcome in the presence of proliferative glomerulonephritis but not in mesangial or membranous glomerulonephritis.

Therefore the best line of treatment would be a conservative approach to address risk factors for progression of renal impairment such as uncontrolled hypertension.

There is no good evidence to support plasma exchange as an effective treatment modality in lupus nephritis.

[Q: 1560] OnExamination 2012 - Nephrology

A 66-year-old man has developed chronic renal failure with a serum urea of 60 mmol/l (2.5-7.5) and creatinine of 650 mol/l (60-110).

Auscultation of the chest reveals a friction rub over the cardiac apex.

Which of the following types of pericarditis is he likely to have?

- 1- Constrictive
- 2- Fibrinous
- 3- Haemorrhagic
- 4- Purulent
- 5- Serous

Answer & Comments

Answer: 2- Fibrinous

The uraemia leads to exudation of fibrin onto the epicardial and pericardial surfaces.

Haemorrhagic pericarditis is more typical of tuberculosis or metastatic tumour.

Serous pericarditis is more typical of collagen vascular diseases.

[Q: 1561] OnExamination 2012 - Nephrology

Which of the following statements regarding idiopathic membranous nephropathy is correct?

- 1- Immune complex deposits are typically seen in the glomerular mesangium.
- 2- It characteristically presents in the first decade of life.
- 3- Males are twice as commonly affected as females.
- 4- Progression to end-stage renal failure is rapid.
- 5- The nephritic syndrome is a characteristic presentation.

Answer & Comments

Answer: 3- Males are twice as commonly affected as females.

Membranous nephropathy is characterised by thickened basement membranes and monotonous granular deposits of IgG and C3 distributed in the epimembranous space of virtually all glomerular capillaries.

The mesangium may be involved at a later stage of the disease and is more typical of secondary disease.

It is typically seen in the over 40 age group with a male predominance of 2 to 1 and is associated with a variable prognosis with 25% developing end stage renal failure (ESRF) over

10 years and 25% going into remission. There is a higher rate of remission for the idiopathic form.

The majority of patients manifest with a pure nephrotic syndrome.

A nephritic presentation is rare.

[Q: 1562] OnExamination 2012 - Nephrology

Which of the following concerning renal blood flow is true?

- 1- Can be measured using the Fick principle
- 2- Is decreased in response to hypoxia
- 3- Is 40% of the cardiac output at rest
- 4- Is higher in the medulla than the cortex
- 5- Is increased when renal nerves are stimulated

Answer & Comments

Answer: 1- Can be measured using the Fick principle

Renal blood flow (RBF) is approximately 25% of cardiac output.

The 'Fick principle' can be used to estimate RBF through clearance.

RBF is higher in the cortex than medulla as one might expect with the increasing glomeruli in this region.

Sympathetic stimuli produce vasoconstriction and RBF should be increased in response to hypoxia.

[Q: 1563] OnExamination 2012 - Nephrology

A 70-year-old female is admitted 12 hours after taking an overdose of aspirin.

Investigations revealed:

Serum Sodium 138 mmol/l (137-144)

Serum Potassium 5.9 mmol/l (3.5-4.9)

Serum bicarbonate 14 mmol/l (20-28)

Serum Urea 18.1 mmol/l (2.5-7.5)

Serum Creatinine 238 mol/l (60-110)

Serum salicylate 1120 mg/l (8)

What is the most appropriate treatment of this patient?

- 1- Haemodialysis
- 2- Haemofiltration
- 3- Intravenous sodium bicarbonate
- 4- Peritoneal dialysis
- 5- Urine alkalinisation

Answer & Comments

Answer: 1- Haemodialysis

This patient is at major risk of aspirin toxicity as reflected by the excessive aspirin concentration and appears to have developed acute renal failure - she is acidotic with an elevated potassium.

Bicarbonate is recommended as a supportive therapy but in this patient haemodialysis is the treatment of choice. The latter is advised when the plasma-salicylate concentration is greater than 700 mg/litre (5.1 mmol/litre) or in the presence of severe metabolic acidosis as recommended within the BNF poisons section.

There is nothing wrong with haemofiltration it just removes the toxin more slowly.

[Q: 1564] OnExamination 2012 - Nephrology

Which one of the following statements is correct?

- 1- Adult polycystic renal disease is inherited as an autosomal recessive trait
- 2- Alport's syndrome affects females more severely than males
- 3- Medullary sponge kidney is typically not inherited but is a congenital condition.

- 4- Nephrogenic diabetes insipidus (DI) is inherited as an autosomal dominant trait
- 5- Reflux nephropathy is inherited as an autosomal recessive trait

Answer & Comments

Answer: 3- Medullary sponge kidney is typically not inherited but is a congenital condition.

Polycystic kidney disease (PKD) is usually autosomal dominant although the infantile form is autosomal recessive.

Nephrogenic DI is usually X linked.

Features of Alport's syndrome (hereditary nephritis, haematuria, progressive renal failure and high frequency nerve deafness) are usually more marked in males.

Neither reflux nephropathy nor medullary sponge kidneys are hereditary conditions.

[Q: 1565] OnExamination 2012 - Nephrology

What is the most likely outcome of minimal change nephropathy with onset at 12 years of age?

- 1- Frequent relapse
- 2- Full renal recovery
- 3- Permanent renal impairment
- 4- Persistent hypertension
- 5- Persistent proteinuria

Answer & Comments

Answer: 2- Full renal recovery

Thirty to 40% of children achieve spontaneous remission and 90% achieve remission following eight weeks of treatment with high dose steroids.

However in adults only around 50% achieve remission.

[Q: 1566] OnExamination 2012 - Nephrology

A 30-year-old man had a blood pressure of 150/100 mmHg.

Clinical examination was normal.

Which one of the following would suggest secondary hypertension?

- 1- 24 Hour urinary protein excretion of 1.6 g (<0.2)
- 2- A creatinine clearance of 90 mL/min (70-140)
- 3- Left ventricular hypertrophy (LVH) criteria on the ECG
- 4- Serum potassium of 3.9 mmol/L (3.5-4.9)
- 5- The presence of arteriovenous (AV) nipping on fundoscopy.

Answer & Comments

Answer: 1- 24 Hour urinary protein excretion of 1.6 g (<0.2)

It is rather young for a 30-year-old to be hypertensive but the presence of such a degree of urinary protein would suggest that the lesion is of renal origin - polyarteritis nodosa, etc.

The potassium concentration is normal and although it does not exclude Conn's it is certainly not suggestive.

LVH would be found with sustained hypertension of any aetiology as would AV nipping.

The creatinine clearance is normal.

[Q: 1567] OnExamination 2012 - Nephrology

A 69-year-old man developed spontaneous bacterial peritonitis complicating his Child's C liver cirrhosis. There was no sign of hypovolaemia.

Which of the following measures was best supported by evidence to prevent the development of hepatorenal syndrome?

- 1- Intravenous dopamine infusion
- 2- Intravenous albumin administration.
- 3- Central venous pressure monitoring
- 4- Regular lactulose use
- 5- Neomycin

Answer & Comments

Answer: 2- Intravenous albumin administration.

Administration of albumin (1.5 g per kilogram of body weight at diagnosis and 1.0 g per kilogram 48 hours later), in addition to antibiotics, has been shown in randomised controlled trial to markedly reduce the risk of hepatorenal syndrome (option B).

The mechanism of albumin (option B) is thought to be its positive effect on circulatory function and other effects, such as antioxidant properties.

Judicious use of diuretics prevents renal failure but this patient has no sign of hypovolaemia.

Central venous pressure monitoring (option C) is not indicated.

Synthetic disaccharide lactulose (option D) is for preventing hepatic encephalopathy, and has no role in preventing hepatorenal syndrome.

Neomycin (option E), by the same token, is thought to be a treatment of choice for hepatic encephalopathy (but limited evidence). In fact, it has been associated with ototoxicity and nephrotoxicity (hence incorrect for option E).

[Q: 1568] OnExamination 2012 - Nephrology

A 67-year-old man presents with sudden

onset atrial fibrillation (ventricular rate of 150/minute). His serum creatinine concentration was 250 $\mu\text{mol/L}$ (70-110).

What is the main factor that determines the choice of loading dose of digoxin in this patient?

- 1- Absorption
- 2- Apparent volume of distribution
- 3- Lipid solubility
- 4- Plasma half life
- 5- Renal clearance

Answer & Comments

Answer: 5- Renal clearance

The pharmacokinetics of digoxin are complex and best explained by a two compartment model.

The loading dose is mainly dependent on the volume of distribution of a drug but this patient has moderate renal failure.

The loading dose is calculated (using various models) by taking into account age, creatinine clearance, body surface area, etc.

Volume of distribution becomes important particularly when body weight is 40 kg or less.

On balance it is the renal failure that is the most important factor in this patient in determining the loading dose.

Digoxin is cleared by the kidneys so the maintenance dose would require adjustment in renal failure.

[Q: 1569] OnExamination 2012 - Nephrology

A 69-year-old man developed *Pseudomonas aeruginosa* infection.

He was started on gentamicin.

Aminoglycoside nephrotoxicity correlates with which one of the following?

- 1- Frequency of aminoglycoside dosing
- 2- High peak and low trough aminoglycoside levels
- 3- Ototoxicity
- 4- Post-antibiotic effect
- 5- Supratherapeutic doses administered once daily

Answer & Comments

Answer: 1- Frequency of aminoglycoside dosing

Aminoglycoside undergoes glomerular filtration and then reabsorption in the proximal tubule where tubular cell injury/death occurs.

Administering aminoglycoside less frequently (option A) allows the kidney more time to "recover" from drug accumulation within the proximal tubular cells and hence minimises nephrotoxicity.

Although aminoglycoside toxicity is not that common, over the past years an experimental animal model has provided insights regarding the mechanisms of cytotoxicity.

Aminoglycoside toxicity occurs in those cell types in which the drug accumulates - primarily the proximal tubules in the cortex.

Multiple human clinical trials (including meta-analysis) as well as animal studies report less nephrotoxicity and equal efficacy when aminoglycosides are given once daily (option E supratherapeutic doses) rather than in conventional divided doses.

This once-daily dosing approach exploits the post-antibiotic bactericidal effect even when drug levels fall below the so-called "therapeutic levels" allowing for a longer dosing interval (thus high peaks and low troughs are desirable, making options B and D incorrect).

Ototoxicity probably has a different underlying pathophysiology from that of nephrotoxicity; the two do not predict one another (option C).

[Q: 1570] OnExamination 2012 - Nephrology

A 59-year-old man with chronic renal failure comes to the surgery complaining of tiredness and lethargy. He has a longstanding history of type 1 diabetes and takes a range of medications.

On examination his BP is 145/84 mmHg.

Investigations show

Haemoglobin 9.4 g/dl (13.5-18)

White cell count $6.4 \times 10^9/L$ (4-10)

Platelets $162 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (134-143)

Potassium 5.0 mmol/l (3.5-5)

Creatinine 219 $\mu\text{mol/l}$ (60-120)

Ferritin 10 Microgram/l (20-60)

Faecal occult blood Negative

Urine Protein ++

Which of the following is the most appropriate next step?

- 1- Erythropoietin
- 2- IV iron transfusion
- 3- Oral ferrous sulphate
- 4- Referral for lower GI endoscopy
- 5- Referral for upper GI endoscopy

Answer & Comments

Answer: 2- IV iron transfusion

This patient has a low serum ferritin, a common occurrence in patients with chronic renal failure. Often patients with chronic renal failure struggle with their eating, and have deficient iron absorption. As such IV iron transfusion is the therapy of choice.

Once iron stores are restored and ferritin is in the normal range, if the patient is still anaemic then erythropoietin would be the next appropriate option.

Given the FOB is negative, GI blood loss is less likely as a cause of his anaemia.

[Q: 1571] OnExamination 2012 - Nephrology

A 63-year-old man, with chronic renal failure and type 2 diabetes, presents to the surgery complaining of generalised aching. He takes twice daily mixed insulin for his diabetes, and ramipril for vascular risk modification.

On examination his BP is 155/92 mmHg, pulse is 75 and regular. Physical examination is otherwise unremarkable.

Haemoglobin 10.9 g/dl(13.5-18)

White cell count $6.1 \times 10^9/L$ (4-10)

Platelets $191 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (134-143)

Potassium 5.3 mmol/l (3.5-5)

Creatinine 320 $\mu\text{mol/l}$ (60-120)

Calcium 2.05 Mmol/l (2.2-2.67)

Urine Protein +

Which of the following is the most likely underlying diagnosis?

- 1- Hypoparathyroidism
- 2- Primary hyperparathyroidism
- 3- Secondary hyperparathyroidism
- 4- Tertiary hyperparathyroidism
- 5- Vitamin D intoxication

Answer & Comments

Answer: 3- Secondary hyperparathyroidism

Chronic renal failure leads to low levels of hydroxylated vitamin D, and hence to hypocalcaemia. This leads to a secondary increase in parathyroid hormone levels.

The second, fourth and fifth options will cause hypercalcaemia.

Standard therapy of choice is three times per week 1-alpha calcidol. Once the calcium approaches the normal range there is often an associated fall in parathyroid levels.

Cinacalcet may be used in patients with end-stage renal disease receiving maintenance haemodialysis, with frequent monitoring of parathormone and calcium.

[Q: 1572] OnExamination 2012 - Nephrology

A 28-year-old man is referred to you by the practice nurse for hypertension management. She has seen him three times over the past four months and his BP is persistently elevated at around 155/92 mmHg.

Your partner has seen him previously for some non-specific right upper quadrant abdominal pain.

On examination of the abdomen you can feel bilateral enlarged kidneys, and a liver edge.

Investigations show

Haemoglobin 12.5 g/dl(13.5-18)

White cell count $6.4 \times 10^9/L$ (4-10)

Platelets $182 \times 10^9/L$ (150-400)

Sodium 139 mmol/l (134-143)

Potassium 4.8 mmol/l (3.5-5)

Creatinine 182 $\mu\text{mol/l}$ (60-120)

Glucose 4.5 Mmol/l (<6.0)

Urine Blood ++

Protein -

Which one of the following is most closely associated with his underlying condition?

- 1- Aortic stenosis
- 2- Coarctation of the aorta
- 3- Diabetes mellitus
- 4- Mitral valve prolapse

5- Tricuspid stenosis

Answer & Comments

Answer: 4- Mitral valve prolapse

A young man presenting with renal failure, haematuria and liver and renal masses raises the suspicion of polycystic kidney disease.

Associated liver cysts are found in around 80% of individuals with polycystic kidney disease. Pancreatic cysts are rarer, and may in some cases be associated with recurrent pancreatitis.

Patients are at increased risk of renal stones, but the predominant increase is seen in urate stones, rather than other types.

Up to 25% of patients may have some degree of mitral valve prolapse.

MODY 5 is associated with hepatic and renal cysts and diabetes mellitus, but that is less likely to be the diagnosis here in the presence of a normal glucose.

Polycystic kidney disease carries an autosomal dominant pattern of inheritance, but may occur as a de novo mutation in 5%.

[Q: 1573] OnExamination 2012 - Nephrology

A 35-year-old man presents with left loin pain and haematuria. He comments that he has had three episodes of similar symptoms in the past.

On examination, he is afebrile and has mild pallor.

Investigations show:

Sodium 140 mmol/L (137-144)

Potassium 3.0 mmol/L (3.5-4.9)

Chloride 115 mmol/L (95-107)

Bicarbonate 12 mmol/L (20-28)

Calcium 2.5 mmol/L (2.2-2.6)

Urea 19 mmol/L (2.5-7.5)

Urinalysis pH 6.5, protein 1+, RBC 1+, White cell count 1+

What is the most likely diagnosis?

1- Bartter's syndrome

2- Conn's syndrome

3- Renal tubular acidosis type 1

4- Renal tubular acidosis type 2

5- Renal tubular acidosis type 4

Answer & Comments

Answer: 3- Renal tubular acidosis type 1

The patient has metabolic acidosis with failure to acidify the urine appropriately, pointing to a diagnosis of renal tubular acidosis (RTA).

Type 1 RTA is due to distal tubule defect to excrete hydrogen ions whereas type 2 RTA is associated with proximal tubule defect to reabsorb bicarbonate.

Type 1 is associated with nephrocalcinosis.

Both types 1 and 2 are associated with hypokalaemia whereas type 4 is characterised by hyperkalaemia.

Bartter's and Conn's syndromes are causes of hypokalaemia and metabolic alkalosis.

[Q: 1574] OnExamination 2012 - Nephrology

A 70-year-old man underwent emergency surgery for an acute abdomen.

Following surgery he was noted to have become oliguric.

Investigations revealed the following:

Sodium 121 mmol/l (137-144)

Potassium 6.6 mmol/l (3.5-4.9)

Chloride 92 mmol/l (95-107)

Urea 17.2 mmol/l (2.5-7.5)

Creatinine 250 µmol/l (60-110)

pH 7.16 (7.36-7.44)

Standard bicarbonate 15.6 mmol/l (20-28)

What is the calculated anion gap for this patient?

- 1- 5 mmol/l
- 2- 10 mmol/l
- 3- 15 mmol/l
- 4- 20 mmol/l
- 5- 25 mmol/l

Answer & Comments

Answer: 4- 20 mmol/l

Anion gap is calculated as $(Na + K) - (Cl + HCO_3)$.

Therefore in this patient, the calculated value is 20 mmol/l.

The normal anion gap is between 8-16 mmol/l. The excessive value here reflects the presence of other acidic anions, and in this case with the metabolic acidosis, the constituents may be lactate, etc.

[Q: 1575] OnExamination 2012 - Nephrology

A 55-year-old man who has received haemodialysis for many years presents with deteriorating discomfort in both shoulders. Past medical history included bilateral carpal tunnel decompression.

His investigations reveal:

Haemoglobin 10 g/dl (13.0-18.0)

ESR 30 mm/1st hr (1-10)

C reactive protein 12 mg/l (<10)

Urate 0.58 mmol/l (<0.45)

What is the most likely diagnosis?

- 1- β_2 microglobulin amyloidosis
- 2- Gout
- 3- Osteoarthritis
- 4- Polymyalgia rheumatica

5- Pseudogout

Answer & Comments

Answer: 1- β_2 microglobulin amyloidosis

The features of shoulder pain associated with a past history of carpal tunnel syndrome in a patient receiving haemodialysis suggests a diagnosis of β_2 microglobulin amyloidosis.

Amyloid deposits composed of β_2 microglobulin as the major constituent protein are mainly localised in joints and periarticular bone and lead to destructive arthropathy which tends to develop five to ten years after the initiation of dialysis.

Death from amyloidosis of gut and heart may occur after 20 years of dialysis.

[Q: 1576] OnExamination 2012 - Nephrology

A 50-year-old man is admitted with cardiogenic shock due to an acute myocardial infarction.

His urine output drops over the next few days. His serum urea increases to 18 mmol/l (2.5 - 7.5), with creatinine of 300 μ mol/l (60 - 110). Urinalysis reveals no protein or glucose, a trace blood, and numerous hyaline casts.

Several days later he develops polyuria and his serum urea and creatinine fall.

Which of the following pathologic findings is most likely to be seen in his kidneys?

- 1- Fusion of podocyte foot processes
- 2- Glomerular crescents
- 3- Hyperplastic arteriolosclerosis
- 4- Mesangial immune complex deposition
- 5- Patchy tubular necrosis

Answer & Comments

Answer: 5- Patchy tubular necrosis

He would have findings of ischaemic acute tubular necrosis from cardiogenic shock.

Fusion of podocyte foot processes is seen in minimal change glomerulonephritis.

Glomerular crescents can complicate any glomerulopathy but, along with mesangial immune complex deposition, is usually an immune-mediated process.

Hyperplastic arteriolosclerosis is the 'onion skin' appearance of arterioles in malignant hypertension.

[Q: 1577] OnExamination 2012 - Nephrology

In chronic untreated renal failure which of the following findings is characteristic?

- 1- Hypercalcaemia
- 2- Hypercalcinuria
- 3- Hyperosmolar dehydration
- 4- Hypokalaemia
- 5- Metabolic alkalosis

Answer & Comments

Answer: 2- Hypercalcinuria

Major pathophysiological abnormalities of chronic renal failure:

Accumulation of nitrogenous waste products

Acidosis: bicarbonate wasting, decreased ammonia secretion, decreased acid excretion

Sodium wasting: solute diuresis, tubular damage

Sodium retention: nephrotic syndrome, CCF, anuria, excess sodium intake

Urinary concentrating defect: nephron loss, solute diuresis

Hyperkalaemia: decreased glomerular filtration rate (GFR), acidosis, hyperaldosteronism

Renal osteodystrophy: decreased intestinal calcium absorption, impaired 1,25-dihydroxy vitamin D production, secondary hyperparathyroidism

Growth retardation: protein calorie deficiency, renal osteodystrophy, acidosis, anaemia

Anaemia: decreased erythropoietin production, low grade haemolysis, inadequate intake

Bleeding tendency: thrombocytopenia, decreased platelet function

Infection: defective granulocyte function

Neurology: uraemia, aluminium toxicity results in fatigue, poor concentration, headache, memory loss, slurred speech, muscle weakness and cramps, seizures and coma

GI ulceration: gastric acid hypersecretion

Hypertension: sodium and water overload, hyperammonaemia

Hypertriglyceridaemia: decreased plasma lipoprotein lipase activity

Pericarditis and cardiomyopathy: cause unknown

Glucose intolerance: tissue insulin resistance.

[Q: 1578] OnExamination 2012 - Nephrology

You are taking part in a clinical trial for a new monoclonal antibody designed to increase the population of T regulatory cells for treating a range of T cell mediated autoimmune disorders.

Which of the following is a feature of T regulatory cells?

- 1- 20% of mature CD4 positive cells are regulatory T cells
- 2- CD4+ CD25+ are thought to be the most important T regulatory cell population
- 3- No CD8+ T regulatory cells exist
- 4- Regulatory cells do not express CD3 receptors
- 5- They produce large amounts of IL-2

Answer & Comments

Answer: 2- CD4+ CD25+ are thought to be the most important T regulatory cell population

CD4+ CD25+ Fox-P3 + T regulatory cells are thought to be the most important T regulatory cell population. They are thought to play an important role in regulating immune responses after invading organisms have been tackled and preventing the development of autoimmunity.

Regulatory T cells are not thought to produce IL-2.

A small population of CD8+ human regulatory T cells has been identified in addition to the larger population of CD4+ regulatory cells.

All T cells express the CD3 receptor, and in humans 5-10% of CD4+ cells are regulatory T cells.

[Q: 1579] OnExamination 2012 - Nephrology

In which of the following circumstances would the treatment of anaemia with erythropoetin still be expected to be effective?

- 1- Aluminium toxicity
- 2- Folate deficiency
- 3- Hyperkalaemia
- 4- Infection
- 5- Iron deficiency

Answer & Comments

Answer: 3- Hyperkalaemia

Epoetin (recombinant human erythropoetin) is used:

In chronic renal failure

To shorten the period of anaemia in those receiving platinum-based chemotherapy and

Prevention of anaemia in premature babies with low birth weight.

Its efficacy may be impaired in certain circumstances particularly with iron deficiency but also with aluminium toxicity, folate deficiency and infection. In the latter the switch to the acute phase proteins impairs its function.

Its efficacy is unimpaired in hyperkalaemia.

[Q: 1580] OnExamination 2012 - Nephrology

Which of the following is the best imaging to identify renal scarring, for instance after childhood febrile urinary tract infection?

- 1- Renal ultrasonography
- 2- Voiding cystourethrography
- 3- Renal DMSA scintigraphy
- 4- Renal DTPA scintigraphy
- 5- Intravenous pyelography

Answer & Comments

Answer: 3- Renal DMSA scintigraphy

Renal scintigraphy with DMSA involves administration of radioactive isotope which is avidly taken up by the renal parenchyma (option C). This permits the identification of regions of decreased uptake that may represent acute inflammation (such as pyelonephritis) or renal scarring.

The technique of dimercaptosuccinic acid DMSA scan (option C) also allows detection of congenital renal disorder.

A small kidney with uniform uptake of DMSA is likely to represent congenital hypodysplasia, whereas a focal area of reduced cortical uptake associated with loss of contours is more likely to represent an infection-related scar.

Renal DTPA involves an isotope that is exclusively filtered by the glomeruli, and is used to give a "perfusion index" and evaluate excretion (obstruction assessment) of the kidney (hence option D incorrect).

Voiding cystourethrography is used to determine whether there is vesicoureteral reflux, which might give an increased risk (but not diagnostic) of renal scarring (hence option B incorrect).

Ultrasonography (option A) also does not reliably detect low-grade scarring.

[Q: 1581] OnExamination 2012 - Nephrology

You are asked to see a haemodialysis patient who developed high fever one hour after initiation of dialysis.

Her dialysis was performed using a tunnelled right internal jugular vein catheter, which has been in place and functioning for one year. No other vascular access has been created.

The current catheter exit site looked clean. Examination showed no cardiac murmur. Blood cultures were drawn from the catheter and her peripheral arm; both grew methicillin-resistant *Staphylococcus aureus* (MRSA).

Which one of the following best describes the correct treatment approach?

- 1- Discharge the patient with oral cloxacillin.
- 2- Administer vancomycin
- 3- Administer vancomycin and remove the central venous catheter

4- Administer vancomycin, keep the central venous catheter but add concomitant antibiotic lock (making use of supratherapeutic concentrations of vancomycin within the catheter lumen after each dialysis session).

5- Administer vancomycin and gentamicin.

Answer & Comments

Answer: 3- Administer vancomycin and remove the central venous catheter

Catheter removal (option C) is strongly recommended in *Staphylococcus aureus* bloodstream infection given the high risk of recurrence in these patients.

Cloxacillin should not be used in MRSA infection (option A incorrect); vancomycin is the drug of choice.

Daptomycin might be needed if minimum inhibitory concentration is ≥ 2 µg/ml indicative of heterogeneous vancomycin intermediate *S. aureus* (hVISA).

We strongly advise catheter removal in the following circumstances of catheter-related bloodstream infection:

- Severe sepsis
- Haemodynamic instability
- Endocarditis
- Evidence of metastatic infection, or
- Persistence of bacteraemia after 48-72 hours of effective antibiotics.

Furthermore, salvage of catheter is more reserved for low-virulence pathogens such as coagulase negative *Staphylococci*, but not MRSA.

Antibiotic lock therapy involves instillation of high-dose antibiotics (prepared using heparin) at the end of each dialysis session into the catheter to maintain high concentrations within the dialysis catheter.

The reported success rate to salvage a tunneled catheter using a combination of systemic antimicrobials and antibiotic lock therapy is only 40% to 55% (option D) with *S. aureus* (compared with 75% to 84% with coagulase negative Staphylococci).

[Q: 1582] OnExamination 2012 - Nephrology

A 42-year-old woman presents to nephrology clinic. She has end stage renal disease due to type 1 diabetes mellitus, and is awaiting transplant. She has been using peritoneal dialysis for six months.

She is complaining of fatigue and you note her haemoglobin to be 9.6 g/dl. You are considering commencing erythropoietin treatment.

What is the most common side effect of erythropoietin when used in patients with chronic kidney disease?

- 1- Blurred vision
- 2- Hepatotoxicity
- 3- Hypertension
- 4- Hypokalaemia
- 5- Thrombocytopenia

Answer & Comments

Answer: 3- Hypertension

Erythropoietin therapy may be considered in patients with chronic kidney disease who have anaemia to increase haemoglobin concentration to 11-12 g/dl.

Serious side-effects of erythropoietin when used in chronic kidney disease are:

- Hypertension - 20% of patients require increased antihypertensive therapy
- Seizures
- Thromboembolic disease
- Anaphylaxis

Failure of treatment - this may be due to untreated iron deficiency, marrow fibrosis, drug therapy, development of antibodies against the treatment, testosterone deficiency in males, or poor compliance.

Blurred vision is not a recognised side effect.

Hepatotoxicity is not a recognised side effect.

New or worsening hypertension is a common side effect of erythropoietin therapy. Twenty per cent of patients will require increased antihypertensive therapy. Erythropoietin may even precipitate a hypertensive crisis.

Hypokalaemia is not a recognised side effect. Instead, hyperkalaemia may occur.

Thrombocytopenia is not a recognised side effect. A dose-dependent rise in platelet count is common, due to erythropoietin affinity for thrombopoietin receptors.

[Q: 1583] OnExamination 2012 - Nephrology

A 23-year-old patient on regular haemodialysis was admitted to the hospital after exertional dyspnoea and atrial fibrillation.

A troponin T laboratory request was made.

What opinion would you formulate?

- 1- A rise in cardiac troponin compared with previous one would support the presence of myocardial ischaemia.
- 2- Any troponin level identifies a patient at greater risk of death compared with a patient without elevated troponin, but this observation does not hold in dialysis population.
- 3- Cardiac troponin test has no diagnostic role in patients undergoing dialysis; it should not be requested.
- 4- He is too young to have cardiovascular disease; troponin test can be omitted.
- 5- None of above.

Answer & Comments

Answer: 1- A rise in cardiac troponin compared with previous one would support the presence of myocardial ischaemia.

The pre-test probability of cardiovascular disease is high in dialysis patients, but the cardiac troponin biomarker should be interpreted in the context of the clinical history and examination for any dialysis patient.

The cardiac troponin tests are frequently elevated in asymptomatic patients undergoing dialysis. In dialysis patients with acute cardiac symptoms, a rising trend in troponin (option A) should still suggest significant myocardial ischaemia.

The option D is incorrect because dialysis patients have exceptionally high risk of cardiovascular disease burden.

A minor issue is that the effect of haemodialysis on cardiac troponin levels remains controversial. By convention, the troponin is best measured on a pre-dialysis blood sample (unless clinical symptoms dictate otherwise).

[Q: 1584] OnExamination 2012 - Nephrology

A 54-year-old man was electively admitted for hernia repair.

Prior to surgery, you detected a serum phosphate level of 0.76 mmol/L (reference range 0.80-1.5 mmol/L). The remainder of his laboratory tests were normal.

What would be the most likely cause?

- 1- Laboratory error
- 2- Hyperventilation after painful venepuncture by a new intern
- 3- Oncogenic hypophosphataemic osteomalacia
- 4- Tumour lysis syndrome

5- X linked hypophosphataemic rickets

Answer & Comments

Answer: 2- Hyperventilation after painful venepuncture by a new intern

The three major mechanisms of hypophosphataemia are

Redistribution of extracellular phosphate into cells

Decreased intestinal absorption and

Depletion due to increased urinary loss.

The correct option in this question is from the first mechanism.

When a patient hyperventilates (option B), there is a rise in intracellular pH (fall in partial pressure of carbon dioxide, which can readily diffuse across cell membranes). The rise in pH then stimulates phosphofructokinase activity, which in turn activates glycolysis.

The options E and C belong to the third mechanism of urinary excretion, but there are no hints to suggest so in the question.

Tumour lysis syndrome (option D) is incorrect because it causes hyperphosphataemia (and hyperkalaemia) instead of low phosphate level.

[Q: 1585] OnExamination 2012 - Nephrology

A 40-year-old gentleman required high doses of intravenous diuretics after his renal transplant for the purposes of fluid management.

Soon after administration he developed hearing loss, tinnitus and vertigo.

Which diuretic is most likely to have caused this?

- 1- Acetazolamide
- 2- Bendroflumethiazide
- 3- Furosemide

4- Spironolactone

5- Triamterene

Answer & Comments

Answer: 3- Furosemide

Use of diuretics has variable side effects, predominantly electrolyte derangement.

Loop diuretics such as furosemide are associated with ototoxicity.

Thiazide diuretics such as bendroflumethiazide do not have this association; neither do potassium sparing diuretics such as spironolactone and triamterene.

Acetazolamide, a carbonic anhydrase inhibitor, is not usually associated with ototoxicity.

[Q: 1586] OnExamination 2012 - Nephrology

Which of the following criteria fit with a diagnosis of syndrome of inappropriate antidiuretic hormone secretion (SIADH)?

1- Addison's disease

2- Hypernatraemia

3- Serum hyperosmolality

4- Urine osmolality greater than 100milliosmoles/kg

5- Urine sodium less than 20mmol/litre

Answer & Comments

Answer: 4- Urine osmolality greater than 100milliosmoles/kg

SIADH is characterised by the following essential criteria:

Normal renal, adrenal and thyroid function

No recent use of diuretics

Clinical euvolaemia

Decreased serum osmolality (less than 275 milliosmoles/kg of water)

Increased urine osmolality (more than 100 milliosmoles/Kg of water) in the context of hypotonic serum.

Addison's disease is an alternative cause of hyponatraemia and does not fit into SIADH.

Hypernatraemia does not fit as the patient should be hyponatraemic in SIADH.

With water retention, serum should be hypo-osmolar rather than hyperosmolar.

Urine sodium less than 20mmol/litre suggests a dilute rather than concentrated urine. The urine sodium is typically >20mmol/litre in SIADH.

Reference:

Ellison D, Berl T. The syndrome of inappropriate antidiuresis. *N Engl J Med.* 17 May 2007;356(20):2064-72.

[Q: 1587] OnExamination 2012 - Nephrology

The healthy adult usually ingests about 8400 mg per week of phosphate through their diet, the majority of which is excreted through faeces and the kidney.

Which of the answers below is the best approximation for the amount of phosphate excreted through the kidneys every week?

1- 1200 mg

2- 2400 mg

3- 3000 mg

4- 5400 mg

5- 6000 mg

Answer & Comments

Answer: 4- 5400 mg

The kidney plays a significant role in phosphate excretion which is why long term

impairment of kidney function disrupts phosphate excretion.

Not only does hyperphosphataemia affect calcium and bone metabolism, but it is associated with increased cardiovascular mortality.

About 5400 mg of phosphate is excreted per week through the kidneys.

The other answers are incorrect estimates of phosphate excretion and should not be selected.

Reference:

Tonelli M, Pannu N, Manns B. Oral phosphate binders in patients with kidney failure. *N Engl J Med.* 8 Apr 2010;362(14):1312-24.

[Q: 1588] OnExamination 2012 - Nephrology

A 37-year-old gentleman presents with renal colic and has confirmed renal stones on radiological imaging.

He is treated with analgesia and sent home with follow up by the urology team. He manages to pass a stone in his urine and this is sent for analysis.

What is the most common composition of renal stones in the general population?

- 1- Calcium oxalate
- 2- Calcium phosphate
- 3- Cystine
- 4- Magnesium ammonium phosphate
- 5- Uric acid

Answer & Comments

Answer: 1- Calcium oxalate

Calcium oxalate stones (option A) are the most frequent, followed by calcium phosphate (option B). Together these make up a significant majority of stones.

Cystine stones (option C) are rare and associated with tubular defects. This answer should not be selected.

Magnesium ammonium phosphate stones (option D) are associated with urea splitting organisms and are not common.

Uric acid stones (option E) make up about 5-10% of stones and are less common than calcium based stones.

Reference:

Moe OW. Kidney Stones: pathophysiology and medical management. *Lancet.* 2006 Jan 28;367(9507):333-44

[Q: 1589] OnExamination 2012 - Nephrology

An 85-year-old woman presents to the medical intake with oliguria and dark urine following a mechanical fall and a long-lie of 20 hours.

She has acute kidney injury with a glomerular filtration rate of 32 ml/min/1.73m³ and creatine kinase is raised at 25,000 (normal range 25-195 iu/l).

You commence initial therapy and prescribe her regular medications.

Which of her medications is it most important to stop in these circumstances?

- 1- Aspirin 75 mg PO OD
- 2- Oral calcium supplements
- 3- Paracetamol 1 g PO QDS
- 4- Salbutamol inhaler PRN
- 5- Simvastatin 40 mg PO ON

Answer & Comments

Answer: 5- Simvastatin 40 mg PO ON

Initial management is that of rehydration and correction of electrolyte disturbances.

Administration of bicarbonate in cases where the urine pH is less than 6.5 despite fluid repletion has been advocated.

Statins should be avoided in patients with rhabdomyolysis due to myotoxicity.

In those taking statins the risk of sporadic rhabdomyolysis is 0.44 per 10,000 patients per year.

Relatively safe in these circumstances are:

- Asprin
- Oral calcium
- Paracetamol
- Inhaled salbutamol.

Statins are myotoxic and can cause rhabdomyolysis independent from trauma. They should be stopped in any patient presenting with the syndrome.

[Q: 1590] OnExamination 2012 - Nephrology

A 14-year-old boy is referred by the practice nurse for follow up with you. He was brought by his mother to see the practice nurse because of progressive hearing loss.

Examination and basic investigations revealed nothing of note, apart from haematuria detected on routine urine testing. Apparently he has an 18-year-old brother who also suffers from deafness and has mild renal impairment.

Investigations show:

- Haemoglobin 13.0 g/dl(13.5-18)
- White cell count $7.1 \times 10^9/L$ (4-10)
- Platelets $199 \times 10^9/L$ (150-400)
- Sodium 140 mmol/l (134-143)
- Potassium 4.7 mmol/l (3.5-5)
- Creatinine 110 $\mu\text{mol/l}$ (60-120)
- ESR 8 (<10)
- Urine Blood +

Which of the following is the most likely diagnosis?

- 1- Alport's syndrome
- 2- Autosomal dominant polycystic kidney disease

- 3- IgA nephropathy
- 4- Membranous nephropathy
- 5- Minimal change disease

Answer & Comments

Answer: 1- Alport's syndrome

Alport's syndrome comprises:

- Sensorineural hearing loss
- Progressive renal failure
- Haematuria
- Ocular abnormalities including cataract formation.

The condition is often associated with an X linked dominant inheritance pattern and hence males are more severely affected.

Prevalence is around 1 in 5000, and the condition occurs because of type 4 collagen mutations. Deafness usually occurs before the onset of renal failure, which is related itself to progressive nephritis.

Rigorous control of hypertension may delay the onset of end stage renal failure, which is seen in 90% of patients with Alport's by the age of 40 years.

[Q: 1591] OnExamination 2012 - Nephrology

A 39-year-old female presents with polyuria and is passing 4 litres of urine per day. She was recently started on a new medication.

Results show:

- Serum Sodium 144 mmol/L(137-144)
- Plasma osmolality 299 mosmol/L(275-290)
- Urine osmolality 210 mosmol/L(350-1000)

Which of the following drugs was prescribed?

- 1- Aspirin
- 2- Fluoxetine
- 3- Glibenclamide
- 4- Lithium

5- Metoprolol

Answer & Comments

Answer: 4- Lithium

This lady has eunatraemia, hypertonicity (high serum osmolality) and inappropriately dilute urine which is consistent with diabetes insipidus.

Of the drugs listed lithium would be the most likely to cause a nephrogenic DI.

[Q: 1592] OnExamination 2012 - Nephrology

A 36-year-old male is referred with chronic renal dysfunction and is discovered to have adult polycystic kidney disease.

Which of the following proteins is associated with the development of APKD?

- 1- Cyst specific binding protein
- 2- Matrix metalloproteinase
- 3- Polycystin-1
- 4- Progesterone binding cyst-protein
- 5- Type 1 collagen

Answer & Comments

Answer: 3- Polycystin-1

Autosomal dominant APKD-1 is a relatively common disorder accounting for approximately 8% of cases of end-stage renal disease (ESRD).

Eighty five percent of cases are due to the defect in PKD-1 locus on chromosome 16p13.3.

PKD-1 encodes a large protein, polycystin, which seems to be involved in cell to cell matrix interaction.

[Q: 1593] OnExamination 2012 - Nephrology

A 28-year-old man presented with hypertension.

On examination he had palpable kidneys and abdominal ultrasound shows bilaterally enlarged cystic kidneys.

Which one of the following conditions is most likely to be present in this patient?

- 1- Mitral stenosis
- 2- Nail dystrophy
- 3- Polycythaemia
- 4- Short stature
- 5- Testicular atrophy

Answer & Comments

Answer: 3- Polycythaemia

The most likely diagnosis here is adult polycystic kidney disease, which is associated with valvular heart abnormalities, incompetence and aneurysms of the cerebral circulation.

However, it is also associated with excessive erythropoietin production and polycythaemia.

[Q: 1594] OnExamination 2012 - Nephrology

A 14-year-old old boy presents with a sore throat and macroscopic haematuria.

What would light microscopy of a kidney biopsy most likely show?

- 1- Collapsed glomeruli
- 2- Crescentic glomerulonephritis
- 3- Mesangial hypercellularity
- 4- Normal tissue
- 5- Segmental sclerosis

Answer & Comments

Answer: 3- Mesangial hypercellularity

The most common cause of macroscopic haematuria in a child is IgA nephritis.

This usually develops one to two days after a sore throat. It is most common in the second and third decades of life and is three times more common in males.

The urine may be frankly bloody or may be the colour of cola. There are no clots in the urine and the haematuria is generally painless although some patients complain of mild loin pain.

It tends to settle spontaneously within five days although the episodes may be recurrent lasting for one to two years.

Renal biopsy will show mesangial IgA deposition on immunofluorescence and light microscopy will show mesangial hypercellularity and matrix expansion.

[Q: 1595] OnExamination 2012 - Nephrology

Which of the following is least true regarding IgA nephropathy?

- 1- Commonly follows a sore throat
- 2- Is the most common glomerulonephritis in the world
- 3- Light chains may be found in the urine
- 4- May be associated with a rash and arthritis
- 5- Predominantly affects young men

Answer & Comments

Answer: 3- Light chains may be found in the urine

IgA nephropathy (Berger's disease) is the most common glomerulonephritis worldwide and characteristically affects young males, presenting with frank haematuria after an episode of pharyngitis.

However it may also present with proteinuria, microscopic haematuria, renal failure or hypertension.

It is probably part of a spectrum of disease with Henoch-Schönlein purpura, which presents with arthritis, rash, abdominal pain and nephritis. In both there are mesangial IgA deposits in the kidney.

[Q: 1596] OnExamination 2012 - Nephrology

A 70-year-old man is admitted to hospital complaining of a twelve day history of loin pain, fevers and occasional rigors. On examination, his temperature is 37.9°C. The renal function is normal.

Urinalysis of a mid stream urine shows:

White cell count >100/mm³

Red cell count >50/mm³

No organisms seen, with no growth.

Which would be your first investigation of choice?

- 1- CT abdomen and pelvis
- 2- Intravenous urogram (IVU)
- 3- Prostatic specific antigen (PSA) measurement
- 4- Transthoracic echocardiogram
- 5- Ultrasound scan renal tract

Answer & Comments

Answer: 5- Ultrasound scan renal tract

Renal cell carcinomas may present in a variety of ways, with only a minority being diagnosed with the classical triad of:

Haematuria

Loin pain

A palpable mass.

Relatively common presentations include:

Anaemia

Hypertension

Pyrexia of unknown origin

Fatigue

Increased plasma viscosity.

Less common presentations include:

Hypercalcaemia

Polycythaemia

Liver dysfunction

Enteropathy

Myopathy.

Urinalysis may show sterile pyuria, as here.

Other causes of sterile pyuria are:

Partially treated urinary tract infections

Tuberculosis of the renal tract

Urethritis and sexually transmitted diseases

Acute glomerulonephritis

Tubulo-interstitial diseases

Adult polycystic kidney disease

Renal stones.

Ultrasound scan of the renal tract would be the first investigation of choice, as it is able to pick up 95% of renal cell carcinomas greater than 1 cm in diameter. It would also exclude infective or inflammatory collections within the renal tract.

If required a computerised tomography (CT) +/- guided biopsy could be obtained to prove the diagnosis.

An intravenous urogram (IVU) was considered the investigation of choice before the advent of ultrasound.

A chest x ray and bone scan would be required to complete the basic investigations.

[Q: 1597] OnExamination 2012 - Nephrology

A 25-year-old man developed bilateral loin pain and frank haematuria.

His symptoms had started 24 hours after developing a sore throat. His blood pressure was 138/88 mmHg. Urinalysis was positive for blood (4+) and protein (2+).

What is the most likely diagnosis?

1- IgA nephropathy

2- Microscopic polyangiitis

3- Nephrolithiasis

4- Post-streptococcal glomerulonephritis

5- Septicaemia

Answer & Comments

Answer: 1- IgA nephropathy

The acute onset of the disease is suggestive of IgA nephropathy which characteristically occurs in young males in their 20s and 30s.

Haematuria occurs within 12-24 hours of pharyngitis, accompanied also by loin pain, muscle pain and fever. Prognosis is usually good especially in children. In adults, between 25-50% may develop end-stage renal failure. No specific treatment is available.

Classically, the patient has streptococcal infection one to three weeks before the onset of acute nephritic syndrome (post-strep GN).

There is a long prodromal systemic illness lasting months or years in microscopic polyangiitis which differs from Wegener's granulomatosis in its absence of respiratory tract granulomatous inflammation.

[Q: 1598] OnExamination 2012 - Nephrology

Acute renal failure may be distinguished from chronic renal failure by which of the following?

1- An increased urinary Na excretion

2- Hyperkalaemia

3- Hypophosphataemia

4- Left ventricular hypertrophy (LVH) on the ECG

5- Renal size on ultrasound scan (USS)

Answer & Comments

Answer: 5- Renal size on ultrasound scan (USS)

Small kidneys on USS suggest chronic renal failure but the following causes of chronic renal failure can present with normal/enlarged kidneys:

- Amyloidosis
- Polycystic kidney disease
- Diabetic glomerulosclerosis
- Scleroderma
- Rapidly progressive glomerulonephritis.

Decreased fractional Na clearance, hyperphosphataemia and hyperkalaemia are features of acute or chronic renal failure.

LVH is probably more likely to be seen in chronic renal failure but is not reliable.

[Q: 1599] OnExamination 2012 - Nephrology

Which of the following is a feature of pseudohypoparathyroidism?

- 1- Increased urinary phosphate and cAMP with PTH infusion
- 2- Low serum calcium and high serum phosphate
- 3- Low serum calcium and low serum phosphate
- 4- Low serum PTH
- 5- Shortened second and third metacarpals

Answer & Comments

Answer: 2- Low serum calcium and high serum phosphate

The biochemistry shows a hypocalcaemia with hyperphosphataemia being usual but elevated parathyroid hormone (PTH) due to resistance to PTH.

This is due to mutation of the PTH receptor with abnormality of the G α subunit with reduced cyclic adenosine monophosphate (cAMP) production following a PTH infusion.

There are associated phenotypic signs including short stature, low IQ and shortened fourth and fifth metacarpals.

[Q: 1600] OnExamination 2012 - Nephrology

A 55-year-old male is admitted to hospital with a four week history of breathlessness and dry cough.

He has a medical history of longstanding asthma and intermittent tension headaches for which he takes simple analgesia.

On clinical examination he appears pale and unwell. His blood pressure is 170/95 mmHg. Heart sounds are normal and the chest is clear. A few non-blanching skin lesions less than 5 mm in size are found on lower limbs.

Investigations show:

Hb 8 g/dl (13.0 - 18.0 g/dL)

WCC $10 \times 10^9/L$ (4 - $11 \times 10^9/L$)

Neutrophils $7 \times 10^9/L$ ($1.5 - 7 \times 10^9/L$)

Lymphocytes $1.8 \times 10^9/L$ ($1.5 - 4 \times 10^9/L$)

Eosinophils $1.2 \times 10^9/L$ ($0.04 - 0.4 \times 10^9/L$)

ESR 55mm/hr (0 - 15 mm/1st hr)

CRP 45mg/L (< 10 mg/L)

Sodium 134mmol/l (137 - 144 mmol/L)

Potassium 4.7mmol/l (3.5 - 4.9 mmol/L)

Creatinine 650mmol/l (60 - 110 μ mol/L)

Urine dipstick shows blood ++ and protein +++.

Renal ultrasound: both kidneys normal in size, no evidence of urinary obstruction.

What is the most likely diagnosis?

- 1- Analgesic nephropathy
- 2- Churg-Strauss syndrome
- 3- IgA nephritis
- 4- Rapidly progressive glomerulonephritis
- 5- Renal amyloidosis

Answer & Comments

Answer: 2- Churg-Strauss syndrome

A. Analgesic nephropathy: incorrect.

This may cause insidious onset of renal failure but is not associated with elevated inflammatory markers, eosinophilia, or asthma.

B. Churg-Strauss syndrome: correct.

Acute presentation with glomerulonephritis, eosinophilia, skin vasculitis, and elevated inflammatory markers on a background of longstanding asthma makes Churg-Strauss the most likely diagnosis.

C. IgA nephritis: incorrect.

IgA nephropathy can be associated with glomerulonephritis but does not explain the skin changes or the asthma.

D. Rapidly progressive glomerulonephritis: incorrect.

Rapidly progressive glomerulonephritis can cause acute presentation with renal failure and rarely with eosinophilia. However, the asthma and skin vasculitis make Churg-Strauss a more likely diagnosis in this scenario.

E. Renal amyloidosis: incorrect.

The presentation in amyloidosis is usually chronic rather than acute and the renal ultrasound scan does not support amyloidosis which is usually associated with enlarged kidneys.

[Q: 1601] OnExamination 2012 - Nephrology

The following are complications of nephrotic syndrome with the exception of which?

- 1- Accelerated hypertension
- 2- Acute renal failure
- 3- Hypocalcaemia
- 4- Pneumococcal infection

5- Venous thrombosis

Answer & Comments

Answer: 1- Accelerated hypertension

Complications also include hyperlipidaemia, protein malnutrition and loss of binding proteins in urine.

Nephrotic syndrome is likely to be associated with hypocalcaemia (vitamin D binding protein and vitamin D lost in nephrotic urine) and hypovolaemia (low blood pressure).

[Q: 1602] OnExamination 2012 - Nephrology

A 22-year-old woman presents with features of nephrotic syndrome and a renal biopsy is performed.

What would you expect to see on light and electron microscopy if you were expecting a diagnosis of minimal change disease?

- 1- Fusion of foot processes of podocytes is seen on light microscopy
- 2- In advanced disease there is hyalinisation of glomeruli seen on light microscopy
- 3- The glomerular basement membrane is normal on electron microscopy
- 4- Tubules may show calcification in lining cells on light microscopy
- 5- Wire-loop lesions are seen on light microscopy

Answer & Comments

Answer: 3- The glomerular basement membrane is normal on electron microscopy

Minimal change disease is typically seen in children less than 6-years-old and in a minority of adults with nephrotic syndrome.

There is no glomerular abnormality on light microscopy.

Electron microscopy shows fusion of foot processes of podocytes and a normal basement membrane.

Treatment is with steroids; disease remission occurs within two weeks although relapse may occur.

A. Fusion of foot processes of podocytes is seen on electron microscopy, not light microscopy.

B. There is no hyalinisation; this is an abnormality seen in other renal diseases, such as amyloidosis.

C. The glomerular basement membrane is normal on electron microscopy, though there is abnormality of podocytes with fusion of foot processes.

D. Tubules may show accumulation of lipid in lining cells on light microscopy, but not calcification.

E. Light microscopy reveals no glomerular abnormalities. Wire-loop lesions are seen in post-infectious glomerulonephritis and lupus nephritis.

[Q: 1603] OnExamination 2012 - Nephrology

During the evaluation of a patient who developed hyperkalaemia, you went through the drug chart.

Which of the following items can be continued without the worry of worsening hyperkalaemia?

- 1- Cyclosporine.
- 2- Digoxin
- 3- Ibuprofen
- 4- Spironolactone
- 5- Thyroxine

Answer & Comments

Answer: 5- Thyroxine

Thyroxine does not cause or exacerbate hyperkalaemia.

Translocation of potassium from the cells into the extracellular space can occur from digoxin overdose due to its dose-dependent Na-K-ATPase pump inhibition.

Other common mechanisms include impaired urinary potassium excretion, notably hypoaldosteronism.

[Q: 1604] OnExamination 2012 - Nephrology

A 74-year-old gentleman with dementia is admitted from the nursing staff, with worsening confusion and inability to eat and drink.

He is clinically dehydrated and his serum sodium laboratory value is measured at 168 mmol/litre.

Assuming the normal serum sodium value is 140 mmol/litre, and his total body water is 40 litres, calculate the free water deficit.

- 1- 1 litre
- 2- 5 litres
- 3- 8 litres
- 4- 15 litres
- 5- 20 litres

Answer & Comments

Answer: 3- 8 litres

The free water calculation is as follows:

(Serum sodium-140)/ 140) x total body water = free water deficit in litres.

$(168-140/140) = 0.2$

$0.2 \times 40 = 8 \text{ litres.}$

The calculation for free water deficit is demonstrated above. 1 litre and 5 litres are underestimates of the free water deficit and so these should not be selected. 15 litres and

20 litres are overestimates and these should not be selected.

[Q: 1605] OnExamination 2012 - Nephrology

A 65-year-old with type 2 diabetes mellitus and a heavy smoking history is started on an angiotensin-converting enzyme inhibitor (ACEI) for high blood pressure.

His creatinine subsequently doubles from 100 $\mu\text{mol/l}$ to 200 $\mu\text{mol/l}$. His general practitioner is concerned about the possibility of renal artery stenosis.

Which of the following investigations would give the highest diagnostic yield for this condition?

- 1- CT abdomen
- 2- CT abdomen with contrast
- 3- Duplex ultrasonography
- 4- Magnetic resonance angiogram (MRA)
- 5- Plasma renin levels

Answer & Comments

Answer: 4- Magnetic resonance angiogram (MRA)

Renal artery stenosis is an important cause of hypertension to recognise.

A rise in creatinine of 15% from baseline is expected with commencement of an ACE-inhibitor.

In this vignette, the large rise in creatinine should warrant a search for renal artery stenosis given the likelihood of vascular disease.

Of the investigations listed, CT abdomen and CT abdomen with contrast should not be selected as CT imaging should be directed towards the aorta and not the abdomen.

Plasma renin levels can be measured but lack specificity.

Duplex ultrasonography is a common first line investigation but may not be diagnostic due to technical difficulties (obese patients, overlying bowel gas).

This leaves MRA as the top choice for investigating renal artery stenosis.

Reference:

Dworkin L, Cooper C. Renal-artery stenosis. *N Engl J Med.* 12 Nov 2009;361(20):1972-8 (log-in required).

[Q: 1606] OnExamination 2012 - Nephrology

A 30-year-old gentleman with a history of heavy alcohol intake presents with macroscopic haematuria.

He reports having an upper respiratory tract infection in the last two days. His renal function continues to decline and he is evaluated in the renal unit. His serum C3 is normal.

What is a biopsy of his kidneys most likely to show?

- 1- C4d staining positive
- 2- Effacement of podocytes on electron microscopy
- 3- Humps in the subepithelial space on electron microscopy
- 4- IgA deposition in the mesangium
- 5- Tram track pattern on light microscopy

Answer & Comments

Answer: 4- IgA deposition in the mesangium

The history of alcohol excess and macroscopic haematuria soon after an upper respiratory tract infection should point the candidate towards IgA nephropathy. This is further confirmed by the normal C3 level.

C4d staining positive is incorrect as this refers to detection of BK virus by the C4d stain.

Podocyte effacement is incorrect as this is diagnostic of minimal change disease.

The hump-like appearance in subepithelial space is characteristic of post-streptococcal glomerulonephritis.

The tram track appearance on light microscopy represents membranoproliferative glomerulonephritis and therefore should not be selected.

[Q: 1607] OnExamination 2012 - Nephrology

The healthy adult kidney excretes 5400 mg per week of phosphate.

What is the maximum amount of phosphate that can be removed by dialysis per week in a patient with anuric renal failure who is dialysis dependent?

- 1- 200 mg
- 2- 500 mg
- 3- 800 mg
- 4- 2700 mg
- 5- 5000 mg

Answer & Comments

Answer: 4- 2700 mg

This question illustrates the the problem with phosphate clearance in patients with renal failure.

Dialysis is able to remove only about half of the phosphate that the healthy kidney would be able to do.

2700 mg is correct and the other answers are incorrect. In such patients, strict dietary control and the use of phosphate binders are necessary to prevent accumulation of phosphate.

Reference:

Tonelli M, Pannu N, Manns B. Oral phosphate binders in patients with kidney failure. N Engl J Med. 8 Apr 2010;362(14):1312-24.

[Q: 1608] OnExamination 2012 - Nephrology

According to the National Kidney Foundation, which of the following glomerular filtration rate (GFR) ranges in ml/min/1.73m² is representative of stage III chronic kidney disease (CKD)?

- 1- 0 - 10
- 2- < 15
- 3- 15- 29
- 4- 30-59
- 5- 60-80

Answer & Comments

Answer: 4- 30-59

This question tests knowledge of the classification of chronic kidney disease.

The table below lists stages of CKD and corresponding GFRs.

Options A, B, C and E are not reflective of stage III chronic kidney disease and are therefore incorrect.

Stage	GFR ml/min/1.73m ²	Description
1	>90	Normal or increased GFR with other evidence of renal damage
2	60-89	Slight decrease in GFR, with other evidence of renal damage
3	30-59	Moderate decrease in GFR, with or without other evidence of renal damage
4	15-29	Severe decrease in GFR, with or without other evidence of renal damage
5	<15	Established renal failure

[Q: 1609] OnExamination 2012 - Nephrology

Which of the following diuretics acts as a carbonic anhydrase inhibitor?

- 1- Acetazolamide
- 2- Bumetanide
- 3- Furosemide
- 4- Metolazone
- 5- Spironolactone

Answer & Comments

Answer: 1- Acetazolamide

Furosemide (option C) is wrong as it acts on the ascending limb of the loop of Henle and prevents active water reabsorption in the kidney by blocking the sodium, potassium, chloride co-transport channel.

Bumetanide (option B) has a similar action.

Metolazone (option D) blocks sodium reabsorption in the distal convoluted channel.

Spironolactone (option E) is an aldosterone receptor antagonist at the cortical collecting duct.

[Q: 1610] OnExamination 2012 - Nephrology

A 28-year-old gentleman presents to hospital feeling unwell with a few days history of diarrhoea and abdominal pain. He reports having eaten at a 'burger van' a few days ago.

He has no previous hospitalisations. His initial laboratory tests show new onset renal impairment, anaemia and low platelets. His clotting is normal.

Which of the following pathogens is most likely to be responsible for this presentation?

- 1- Clostridium difficile
- 2- Escherichia coli
- 3- Enterococcus faecalis

- 4- Methicillin resistant D. Staphylococcus aureus (MRSA)
- 5- Streptococcus viridans

Answer & Comments

Answer: 2- Escherichia coli

Haemolytic uraemic syndrome is a syndrome composing of the triad of:

Microangiopathic haemolytic anaemia
Low platelets and
Renal failure.

A number of pathogens are implicated including Escherichia coli.

This presentation is not classical of C. difficile as we are given no risk factors for this in the question stem so option A is incorrect.

Enterococcus faecalis is a bowel commensal which is unlikely to cause the degree of pathology described in this case so option C is incorrect.

There is no reason to suspect this gentleman is MRSA positive so option D is incorrect.

Streptococcus viridans is an upper respiratory tract and throat bacteria. This patient's presentation does not involve that organ system so option E is incorrect.

[Q: 1611] OnExamination 2012 - Nephrology

Which of the following immune complex glomerulonephritides is associated with a normal complement C3?

- 1- Cryoglobulinaemia
- 2- Endocarditis
- 3- IgA nephropathy
- 4- Membranoproliferative GN
- 5- Post-streptococcal GN

Answer & Comments

Answer: 3- IgA nephropathy

Immune complex glomerulonephritides can be classified based on normal or decreased C3.

Of the answers above IgA nephropathy should be selected as this is associated with normal C3.

Cryoglobulinaemia is associated with reduced C3 and C4.

Infective endocarditis is associated with a decrease in complement (C3 and C4).

Both membranoproliferative GN and post-streptococcal GN are associated with reduced C3.

[Q: 1612] OnExamination 2012 - Nephrology

A 28-year-old gentleman presents with haematuria, progressive renal impairment and hearing problems.

Of note there is a strong family history of renal problems with family members requiring dialysis. Further work up of this gentleman leads to a diagnosis of Alport's syndrome.

What is the characteristic otological problem associated with this condition?

- 1- Conductive deafness
- 2- Mastoiditis
- 3- Perforated ear drum
- 4- Recurrent otitis media
- 5- Sensorineural deafness

Answer & Comments

Answer: 5- Sensorineural deafness

Alport's syndrome is associated with sensorineural hearing loss (due to impaired adhesion of the organ of Corti which contains the auditory sensory cells) so option E should be selected.

It is not associated with conductive deafness so option A is incorrect.

There is no increased association with ear infections such as otitis media (option D), mastoiditis (option B) and perforated ear drum (option C). Hence these answers should not be selected.

[Q: 1613] OnExamination 2012 - Nephrology

Inappropriately high parathyroid hormone secretion (PTH) in renal patients can lead to significant bone reabsorption and premature fractures.

Which one of the following is known to stimulate parathyroid hormone production?

- 1- Calcium acetate tablets
- 2- Hypercalcaemia
- 3- Hyperphosphataemia
- 4- Hypophosphataemia
- 5- Serum alkaline phosphatase

Answer & Comments

Answer: 3- Hyperphosphataemia

Hyperphosphataemia (option C) is known directly to stimulate the parathyroid gland to produce PTH.

Hypercalcaemia (option B) and hypophosphataemia (option D) should suppress PTH production via negative feedback pathways. Hence options B and D are incorrect.

Phosphate binders such as calcium acetate (option A) are used to reduce phosphate in the serum and hence lower PTH production.

Serum alkaline phosphatase has no bearing on PTH production but may rise in hyperparathyroid states due to increased bone turnover.

Options A and E are therefore incorrect.

[Q: 1614] OnExamination 2012 -
Nephrology

A 16-year-old boy presents with periorbital and peripheral oedema which has developed over the past few weeks. He had a previous episode some two years earlier but this responded over the course of a few weeks to a course of prednisolone.

On examination he has a BP of 141/80 mmHg, with pulse of 68. His chest is clear but he has bilateral pitting oedema.

Investigations show:

Haemoglobin 12.9 g/dl(13.5-8)

White cell count $6.1 \times 10^9/L$ (4-10)

Platelets $209 \times 10^9/L$ (150-400)

Sodium 139 mmol/l (134-143)

Potassium 4.8 mmol/l (3.5-5)

Creatinine 110 $\mu\text{mol/l}$ (60-120)

Albumin 24 g/l (30-50)

Urine Protein ++

Which of the following represents the most appropriate management plan for him?

- 1- Oral combination corticosteroids and cyclophosphamide
- 2- Oral corticosteroids
- 3- Oral cyclophosphamide
- 4- Oral methotrexate
- 5- Renal biopsy

Answer & Comments

Answer: 2- Oral corticosteroids

The age of this patient and his previous response to corticosteroids is suggestive of an underlying diagnosis of minimal change nephropathy. As such, a further course of corticosteroids is the treatment of choice.

Given the inherent but low risks associated with renal biopsy, it is usually only attempted

when three or more episodes of oedema have occurred.

Very few patients with minimal change disease actually progress to end stage renal disease, and only around 10% of children with the disease suffer from hypertension.

[Q: 1615] OnExamination 2012 -
Nephrology

A 57-year-old woman who has been receiving haemodialysis for the past five years is found dead in bed by her husband. She had a long history of type 1 diabetes for over 20 years and in her later years suffered from neuropathy and retinopathy as well as chronic renal failure. Most recently she was under investigation for angina.

Which of the following is the most likely cause of death in this patient?

- 1- Hyperkalaemia
- 2- Hypoglycaemia
- 3- Myocardial infarction
- 4- Pulmonary embolus
- 5- Stroke

Answer & Comments

Answer: 3- Myocardial infarction

Patients who undergo long term haemodialysis suffer from increasing arterial calcification, which is associated with both increased risk of myocardial infarction and stroke, but the greatest absolute increase is in MI rates.

Interestingly, trials of high dose statins have proved disappointing in the dialysis population, suggesting that calcification drives much of the increased risk.

Whilst both hypoglycaemia and hyperkalaemia are alternative possibilities as causes of death, myocardial infarction is more likely than both to have been responsible.

[Q: 1616] OnExamination 2012 -
Nephrology

Which is the predominant site of effect of thiazide diuretics?

- 1- Cortical collecting duct
- 2- Early distal tubule
- 3- Late distal tubule
- 4- Proximal tubule
- 5- Thick ascending limb, loop of Henle

Answer & Comments

Answer: 2- Early distal tubule

Thiazide diuretics act on the cortical diluting segment of the nephron, predominantly in the early distal tubule.

Loop diuretics mainly act on the thick ascending limb of the loop of Henle.

Potassium sparing diuretics, for example amiloride, act on the distal nephron.

[Q: 1617] OnExamination 2012 -
Nephrology

A 63-year-old female with a 12 year history of hypertension and diabetes has been treated with metformin 1g bd, gliclazide 80 mg bd, rosuvastatin 10 mg daily, ramipril 10 mg daily, aspirin 75 mg daily and amlodipine 10 mg daily for the last two years.

At annual review her blood pressure is 138/82 mmHg, fundi reveal background diabetic retinopathy, foot pulses are normal but she has evidence of a peripheral sensory loss to the ankles in both feet.

Her results show:

HbA1c 7.2%(3.8-6.4)

Urea 12.5 mmol/L(2.5-7.5)

Creatinine 176 µmol/L(60-110)

Cholesterol 4.8 mmol/L(<5.2)

Which of the following drugs should be withdrawn?

- 1- Aspirin
- 2- Gliclazide
- 3- Metformin
- 4- Ramipril
- 5- Rosuvastatin

Answer & Comments

Answer: 3- Metformin

This patient has evidence of chronic renal impairment with elevated creatinine and urea. Guidelines currently suggest that metformin should be stopped if creatinine is above 150 µmol/L.

The estimated prevalence of life-threatening lactic acidosis is one to five cases per 100 000, with mortality in reported cases up to 50%. Traditionally this complication has been thought of as secondary to an accumulation of the drug.

Metformin is excreted unchanged in the urine with the half life prolonged and renal clearance decreased in proportion to any decrease in creatinine clearance. This may occur chronically in chronic renal impairment, or acutely with dehydration, shock, and intravascular administration of iodinated contrast agents, all of which have the potential to alter renal function.

Tissue hypoxia also has a significant role, and acute or chronic conditions that may predispose to this condition, such as sepsis, acute myocardial infarction, pulmonary embolism, cardiac failure and chronic liver disease, may act as triggers.

As the patient appears to have chronic renal impairment and as she has been on ramipril for a considerable period it is unlikely that she has renal artery stenosis requiring the withdrawal of the angiotensin-converting enzyme inhibitor (ACEi).

[Q: 1618] OnExamination 2012 -
Nephrology

A 70-year-old man was referred by his GP with difficulty in treating hypertension.

He had longstanding hypertension which had been well controlled over many years but recently he was found to have a blood pressure of 190/110 mmHg which proved resistant to additional treatment.

He was generally asymptomatic and complied with medication. Investigations showed normal U+Es.

Which one of the following is the most likely cause?

- 1- Chronic pyelonephritis
- 2- Conn's syndrome (primary hyperaldosteronism)
- 3- Pheochromocytoma
- 4- Polycystic kidney disease
- 5- Renovascular disease

Answer & Comments

Answer: 5- Renovascular disease

Primary hyperaldosteronism (Conn's syndrome) typically has hypokalaemic alkalosis.

One should also suspect Conn's with patients resistant to conventional antihypertensive treatment and with the electrolytes in the direction of Conn's without necessarily being outside the normal range (plasma Na > 140 and K < 4).

However, in this patient's case he has longstanding hypertension but has deteriorated. Therefore the most likely cause is renovascular disease related to his hypertension.

[Q: 1619] OnExamination 2012 -
Nephrology

A 63-year-old woman presents following a

visit to the well woman clinic where she is noted to be hypertensive.

She has a history of hip osteoarthritis for which she has taken regular paracetamol.

On examination she is obese with a BMI of 35 (<25), has a blood pressure of 180/100 mmHg and glycosuria is noted.

Her investigations show:

Fasting plasma glucose 18.3 mmol/L (3.0-6.0)

Serum urea 9.8 mmol/L (2.5-7.5)

Serum Creatinine 129 µmol/L (60-110)

24 hour urine protein concentration 1.8 g/d (<0.2)

Normal ultrasonic appearances of both kidneys

Which of the following is the most likely diagnosis?

- 1- Analgesic nephropathy
- 2- Chronic glomerulonephritis
- 3- Diabetic nephropathy
- 4- Hypertensive nephropathy
- 5- Ischaemic nephropathy

Answer & Comments

Answer: 3- Diabetic nephropathy

This patient is diabetic and has proteinuria.

Although diabetic nephropathy usually takes five or more years to evolve, this patient is likely to have had the condition for many years prior to it now being diagnosed.

Ischaemic nephropathy due to renal artery stenosis is unlikely in the presence of a normal renal ultrasound.

Analgesic nephropathy would be a consequence of non-steroidal anti-inflammatory drugs (NSAIDs) not paracetamol.

Hypertensive nephropathy is a possibility but is less likely in the context of her proteinuria and moderately elevated BP.

[Q: 1620] OnExamination 2012 -
Nephrology

A 68-year-old male diagnosed with nephrotic syndrome receives steroid therapy without benefit.

His investigations show an albumin of 20 g/L (37-49), total cholesterol of 12 mmol/L (<5.2), dipstick urinalysis reveals +++ protein and a renal biopsy shows focal segmental glomerulosclerosis.

Which one of the following is most likely to preserve renal function?

- 1- Dietary salt restriction
- 2- Low dietary protein intake
- 3- Ramipril
- 4- Simvastatin
- 5- Warfarin

Answer & Comments

Answer: 3- Ramipril

Approximately 50% of subjects with focal segmental glomerulosclerosis (FSGS) do not respond to steroid therapy but angiotensin-converting enzyme (ACE) inhibitors are a recognised strategy to slow the progression of renal disease.

This patient is clearly at high risk of cardiovascular disease with a very high cholesterol but the question specifically asks about renal disease.

[Q: 1621] OnExamination 2012 -
Nephrology

A 40-year-old man presents with acute weakness and palpitations.

Investigations reveal:

- Sodium 143 mmol/l (137-144)
Potassium 8.0 mmol/l (3.5-4.9)
Urea 35 mmol/l (2.5-7.5)
Creatinine 450 µmol/l (60-110)

Bicarbonate 5 mmol/l (20-28)

What is the best immediate therapy?

- 1- Intravenous calcium gluconate
- 2- Intravenous dextrose and insulin
- 3- Intravenous sodium bicarbonate
- 4- Nebulised salbutamol
- 5- Rectal calcium resonium

Answer & Comments

Answer: 1- Intravenous calcium gluconate

This patient appears to have acute renal failure with severe acidosis, hyperkalaemia and palpitations.

The patient should be rehydrated, treated with insulin and given bicarbonate, but the immediate treatment particularly in the context of a life threatening arrhythmia would be calcium gluconate.

[Q: 1622] OnExamination 2012 -
Nephrology

A 35-year-old presents to the infectious disease team following a new diagnosis of HIV.

Her CD4 count is 150 cells/ mm³ and a viral load is 10,000. She is commenced on anti-retrovirals.

At a follow up appointment four weeks later she has routine blood tests, of which her creatinine is shown below. She is euvolaemic and has not taken any additional medications over the counter.

On presentation her results showed:

Serum creatinine 80 µmol/l (60-90)

and four weeks later:

Serum Creatinine 220 µmol/l (60-90).

Which of the following answers is most likely to be responsible for her acute renal impairment?

- 1- Efavirenz

- 2- HIV associated nephropathy
- 3- Lamivudine
- 4- Non-compliance with medications
- 5- Tenofovir

Answer & Comments

Answer: 5- Tenofovir

This question requires knowledge of the side effects of anti-retroviral medications.

Non-compliance (option D) should not be selected as there is no reason why this would specifically affect renal function. This would be assessed with repeat viral loads and CD4 counts to which we do not have access.

Option B, HIV associated nephropathy, is incorrect given the speed of deterioration in renal function.

Of the anti-retroviral medications, tenofovir is associated with acute renal dysfunction (option E) more than efavirenz (option A) and lamivudine (option C).

[Q: 1623] OnExamination 2012 - Nephrology

Which of the following is a known risk factor for the development of chronic rejection of kidney transplantation?

- 1- Age
- 2- Anti-smooth muscle antibodies
- 3- Presence of anti-HLA antibodies
- 4- Smoking
- 5- Toxoplasma infection

Answer & Comments

Answer: 3- Presence of anti-HLA antibodies

Chronic rejection is characterised by fibrosis of normal organ structures.

The pathogenesis of chronic rejection is not clear - some prefer the term "chronic allograft

dysfunction" since both immunological (antigen-dependent and antigen-independent) and non-immunological factors have been identified.

Cell-mediated and humoral immune mechanisms have been implicated in this form of graft rejection.

It has also been suggested that rejection is a response to chronic ischaemia caused by injury to endothelial cells.

Proliferation of intimal smooth muscle is observed leading to vascular occlusion.

The fact that chronic rejection is rare in transplants between human leukocyte antigen (HLA)-identical siblings suggests that HLA-antigen dependent immunological factors are important.

Risk factors include:

- Number of previous acute rejection episodes
- Presence of anti-HLA antibodies
- Anti-endothelial antibodies
- Cytomegalovirus infection
- Dyslipidaemia
- Hypertension
- Functional mass of the donor kidney and
- Delayed graft function (a clinical manifestation of ischaemia/reperfusion injury).

[Q: 1624] OnExamination 2012 - Nephrology

You are auditing the nephrology department's rates of peritoneal dialysis peritonitis, observing the proportion of cases that are culture positive and the associated organism.

In the United Kingdom, what is the most common causative organism in peritoneal dialysis peritonitis?

- 1- Coagulase negative Staphylococcus

- 2- Enterococcus spp.
- 3- Escherichia coli
- 4- Pseudomonas spp.
- 5- Staphylococcus aureus

Answer & Comments

Answer: 1- Coagulase negative Staphylococcus

Ten percent to 30% of cases are culture negative.

At 20-25% overall, coagulase negative Staphylococcus is the most commonly cultured organism.

With improved hygiene and technique, rates of staphylococcal infection are falling.

Intra-abdominal pathology (such as a ruptured viscus) should be considered if more than one organism is grown, especially if Gram negative or anaerobic.

Repeated treatment increases the risk of resistant organisms. This may require loss of catheter and switch to haemodialysis.

Coagulase negative Staphylococcus is the most commonly cultured organism in peritoneal dialysis peritonitis. It represents 20-25% of cases. It is a skin commensal that opportunistically causes infection through the catheter site.

Enterococcus represents 1-5% of cases and occurs less frequently than coagulase negative Staphylococcus.

Escherichia coli is less common.

Overall, Gram negative organisms represent 10-15% of cases.

Pseudomonas represents 5% of cases and occurs less frequently than coagulase negative Staphylococcus.

Staphylococcus aureus represents 10-15% of cases and occurs less frequently than coagulase negative Staphylococcus.

[Q: 1625] OnExamination 2012 - Nephrology

A 60-year-old man presents to nephrology clinic with fatigue. He has a history of stage four chronic kidney disease, secondary to hypertension.

A full blood count reveals a normocytic anaemia with a haemoglobin concentration of 9.7 g/dl. White cell count and platelets are within normal limits.

You are considering commencing treatment for his anaemia.

What is the most appropriate investigation to help guide treatment?

- 1- Peripheral blood film
- 2- Serum erythropoietin
- 3- Serum ferritin
- 4- Serum lactate dehydrogenase
- 5- Urinary 24 hour creatinine clearance

Answer & Comments

Answer: 3- Serum ferritin

Although endogenous erythropoietin deficiency is a common cause of anaemia, iron deficiency may co-exist and is easily treatable.

Iron deficiency contributes to a poor response to erythropoiesis-stimulating agents.

In patients with haemoglobin less than 11 g/dl or who are symptomatic, the following baseline investigations are required:

Full blood count

Serum ferritin to assess iron status (plus further evaluation of iron stores if indicated)

Serum C reactive protein (CRP) to assess inflammation.

Further investigations may be warranted, such as vitamin B₁₂, folate, reticulocyte count, serum/urine protein electrophoresis and tests for haemolysis.

Measurement of serum erythropoietin adds no benefit when diagnosing and managing anaemia in chronic kidney disease due to unreliability of the test.

With a normal white cell and platelet count, a peripheral blood film is not indicated as an initial investigation.

Iron deficiency is common in patients with chronic kidney disease and is easily treatable. It may be present despite a normal mean corpuscular volume and normal mean corpuscular haemoglobin, which do not fall until iron deficiency is long standing.

If exogenous erythropoietin therapy were to be commenced, limited or no benefit would be noted in patients with iron deficiency. Therefore serum ferritin should be measured in all patients with anaemia in the context of chronic kidney disease.

Serum lactate dehydrogenase is not indicated as there is no indication of haemolysis from the history.

Urinary 24 hour creatinine clearance may be useful in the assessment of renal disease but will not aid further evaluation of anaemia in this case.

[Q: 1626] OnExamination 2012 - Nephrology

Creatinine has a number of limitations as an estimate of glomerular filtration rate (GFR), including variation with muscle mass and age.

Which of the following answers represents a novel marker of estimating GFR?

- 1- Alpha amyloid protein
- 2- Cystatin c
- 3- Inulin
- 4- Insulin-like growth factor 1 (IGF-1)
- 5- Nystatin

Answer & Comments

Answer: 2- Cystatin c

This question demonstrates knowledge of markers of glomerular filtration rate.

Serum creatinine has limitations as a marker of GFR.

Nystatin is an antifungal agent and not a marker of GFR.

Inulin is a valid marker of renal function and was used experimentally in the past for many years.

Alpha amyloid protein and IGF-1 have no role in estimating renal function.

[Q: 1627] OnExamination 2012 - Nephrology

Which of the following is the best description of the drug cinacalcet?

- 1- Binding phosphate in the gut lumen
- 2- Calcimimetic
- 3- Increasing absorption of calcium from the gut
- 4- Preventing ADH action at the distal collecting duct
- 5- Preventing osteoclast action

Answer & Comments

Answer: 2- Calcimimetic

Cinacalcet is a calcimimetic.

Binding phosphate in the gut lumen is incorrect; this represents the action of phosphate binders.

Increasing absorption of calcium from the gut is incorrect as it represents the action of vitamin D.

Cinacalcet does not have an action of antidiuretic hormone (ADH) and so preventing ADH action at the distal collecting duct is incorrect.

Neither does it affect osteoclasts directly; preventing osteoclast action is wrong as this represents the action of bisphosphonates.

[Q: 1628] OnExamination 2012 - Nephrology

A 60-year-old female is referred to the medical intake with serum potassium of 6.5 mmol/L.

She has a history of type 2 diabetes mellitus, chronic obstructive pulmonary disease (COPD), previous myocardial infarction and osteoarthritis.

Which of the following medications are most likely to contribute to her hyperkalaemia?

- 1- Aspirin
- 2- Clopidogrel
- 3- Insulin glargine
- 4- Lisinopril
- 5- Salbutamol inhaler

Answer & Comments

Answer: 4- Lisinopril

This question requires basic knowledge of medications that can contribute to hyperkalaemia.

Anti-platelet agents themselves are not associated with potassium changes and so options A and B are incorrect.

Insulin (option C) and salbutamol (option E) cause potassium to shift from extra to intracellular compartments and so would not cause a rise in serum potassium.

[Q: 1629] OnExamination 2012 - Nephrology

A 60-year-old female presents with cough, haemoptysis and haematuria.

Her laboratory tests show impaired renal function. After a thorough work up, anti-glomerular basement membrane (anti-GBM)

antibody is positive, diagnosing Goodpasture's syndrome.

Which class of antibody is the anti-GBM most likely to be?

- 1- IgA
- 2- IgD
- 3- IgE
- 4- IgG
- 5- IgM

Answer & Comments

Answer: 4- IgG

Anti-GBM in the Goodpasture's syndrome are rarely due to IgA (option A) and IgM (option E); they are less frequent than IgG.

Hence options A and E are incorrect.

IgD and IgE are not implicated as anti-GBM so both options B and C are incorrect.

[Q: 1630] OnExamination 2012 - Nephrology

Which of the following diabetic medications increases the risk of contrast induced nephropathy?

- 1- Acarbose
- 2- Exenatide
- 3- Gliclazide
- 4- Insulin
- 5- Metformin

Answer & Comments

Answer: 5- Metformin

Contrast induced nephropathy is a complication of intravenous contrast given during some radiological procedures. Existing renal impairment, dehydration and the use of metformin increase the risk of this.

Metformin is usually withheld for 48 hours after the use of contrast.

Option A, acarbose, should not be selected because it is a post-prandial glucose regulator and has no relation to contrast induced nephropathy.

Likewise, options B, C and D are safe to use after the administration of intravenous contrast and do not increase the risk of contrast induced nephropathy.

Reference:

Barrett BJ, Parfrey PS. *Clinical practice. Preventing nephropathy induced by contrast medium. N Engl J Med.* 2006 Jan 26;354(4):379-86

[Q: 1631] OnExamination 2012 - Nephrology

A patient who was recently admitted to the medical receiving unit with general malaise has been found to have deranged renal function. Your registrar asks you to arrange 'an urgent scan' to exclude obstruction of the kidneys.

Which of the following is most appropriate?

- 1- CT KUB (kidneys, ureters and bladder)
- 2- MR angiography of renal tract
- 3- MRI kidneys
- 4- Plain abdominal x ray
- 5- Ultrasound renal tract

Answer & Comments

Answer: 5- Ultrasound renal tract

Acute imaging of the kidneys is intended primarily to exclude obstructive uropathy, which would be demonstrated on ultrasound imaging. Ultrasound imaging is a safe, non-invasive means rapidly to exclude a correctable cause of renal impairment. It is readily available in most hospitals and can be performed by a sonographer or radiologist.

A CT KUB is indicated when the USS (and clinical history) is suggestive of the presence of renal calculi, whether or not they are causing obstruction.

MR imaging of the kidneys can help determine the nature of a lesion seen on ultrasound imaging. It is expensive, time-consuming, and not available in all locations. Furthermore many patients with magnetic materials inserted, for example, pacemakers, defibrillators are precluded from entering the strong magnetic field. These factors preclude its use as a first-line approach to excluding acute obstruction of the kidney.

MR angiography is helpful to exclude renal artery stenosis. This will not confirm or refute the presence of post-renal obstruction.

A plain abdominal x ray will occasionally demonstrate the presence of radio-opaque renal calculi, but cannot confirm or refute the presence of post-renal obstruction. It should not be done routinely in all patients with acute renal impairment unless there is a strong clinical suspicion of renal calculi (in which case most patients will proceed to having a CT KUB examination).

[Q: 1632] OnExamination 2012 - Nephrology

A 44-year-old woman with type 1 diabetes mellitus has not attended the diabetic clinic for five years.

Examination shows no abnormalities.

Investigations show:

Haemoglobin 9 g/dL (11.5-16.5)

MCV 94 fL (80-96)

Haematocrit 28%

HbA1c 10.1% (3.8-6.4)

A blood smear shows normochromic, normocytic anaemia.

Which of the following is the most likely cause?

- 1- Acute blood loss
- 2- Chronic lymphocytic leukaemia (CLL)
- 3- Erythropoietin deficiency
- 4- Microangiopathic haemolysis
- 5- Sideroblastic anaemia

Answer & Comments

Answer: 3- Erythropoietin deficiency

The most likely cause is progressive renal failure which leads to reduced release of erythropoietin from the kidneys.

Sideroblastic anaemia (myelodysplasia) is seen in older age groups.

CLL or microangiopathic haemolysis are possible causes but unlikely.

[Q: 1633] OnExamination 2012 - Nephrology

Patients with end stage renal failure on haemodialysis may have anaemia secondary to multiple causes.

One important cause is erythropoietin (EPO) deficiency. EPO injections can be given intravenously or subcutaneously and are effective, providing that iron stores are replete.

Which of the following blood tests in conjunction with serum ferritin is the recommended test for iron status in patients with anaemia?

- 1- C reactive protein (CRP)
- 2- Erythrocyte sedimentation rate (ESR)
- 3- Mean cell volume
- 4- Serum iron
- 5- Transferrin saturation

Answer & Comments

Answer: 5- Transferrin saturation

According to NICE guidelines, ferritin in conjunction with either transferrin saturation or percentage hypochromic red cells is used to assess anaemia.

Low mean cell volume (option C) can be indicative of iron deficiency but may also be attributable to other causes and so this is incorrect.

Option D, although a marker of iron status is not a recommended test, is incorrect.

Options A and B are inflammatory markers and have no bearing on the management of iron status in anaemia in chronic kidney disease. Hence these are incorrect.

Reference:

Anaemia Management in People with Chronic Kidney Disease. NICE Quick Reference Guide February 2011

[Q: 1634] OnExamination 2012 - Nephrology

A 30-year-old woman receives a cadaveric renal transplantation after having had renal failure, with a neuropathic bladder for which she performed intermittent self-catheterisation.

Six months after transplantation she presents with acute pain in the region of the transplanted kidney.

Which one of the following is the most likely reason for the pain?

- 1- Acute retention of urine
- 2- Allograft rejection
- 3- Pyelonephritis
- 4- Renal calculi
- 5- Renal infarction

Answer & Comments

Answer: 3- Pyelonephritis

Acute urinary retention would not cause pain overlying a transplanted kidney, and as this

lady self-catheterises, it would be an unlikely occurrence.

Due to the elapsed time between the transplant and this episode, allograft rejection can be discounted. This is because chronic rejection (more than three months post transplant) is a painless process, with difficult to control hypertension, proteinuria and slowly rising serum creatinine.

Accelerated rejection (one to five days post transplant) can present with fever, an acutely tender swollen graft, and rapidly rising serum creatinine.

Acute rejection (five days to three months) is clinically silent in the majority, but can present with a swollen, tender kidney.

Renal infarction can also be discounted. This can be a surgical complication of renal transplantation, but it presents early with a calyceal fistula and urinary leak.

Renal stones could cause acute pain in the region of a transplanted kidney, but would be less likely in this patient than acute retention of urine.

The answer in this case is acute pyelonephritis.

This patient is in the intermediate stage of the post-transplantation immunosuppression, when the patient is most immunocompromised (three to six months post-transplant).

She is at high risk of an acute episode of pyelonephritis in the transplanted kidney, due to the immunosuppression, the neuropathic bladder and self-catheterisation. This would present like an acute rejection episode, with a tender swollen graft, low-grade pyrexia, and deteriorating graft function.

This would be commonly associated with septicaemia in this patient, and requires parenteral antibiotics.

If this lady were to be managed as a transplant rejection, with high dose intravenous steroids, the result could be catastrophic.

[Q: 1635] OnExamination 2012 - Nephrology

A 22-year-old woman presents with right loin pain, oliguria and coke-coloured urine.

Blood pressure is increased at 160/70 mmHg and urinary dipstick shows protein ++++ and blood +++. Microscopy is awaited.

Blood tests reveal:

Hb 12.6 (11.5 - 16.5 g/dL)

WCC 8.4 (4 - 11 x 10⁹/L)

Platelets 412 (150 - 400 x 10⁹/L)

Na 137 (137 - 144 mmol/L)

K 5.7 (3.5 - 4.9 mmol/L)

Creatinine 263 (60 - 110 µmol/L)

Urea 25.2 (2.5 - 7.5 mmol/L)

What is the most appropriate next investigation of this patient?

- 1- Renal angiography
- 2- DMSA scan
- 3- Plain abdominal KUB
- 4- Renal biopsy
- 5- Renal ultrasound scan

Answer & Comments

Answer: 5- Renal ultrasound scan

Although this patient has features of nephritic syndrome and may warrant biopsy in the future, a renal ultrasound scan is the best next investigation.

Renal ultrasound allows one to assess kidney size, the presence of hydronephrosis, cysts or tumours and any developmental abnormalities. Doppler traces also allow renal blood flow to be assessed.

If a clear identifiable precipitant is identified as the cause of the acute kidney injury an ultrasound may not be appropriate.

If a patient is in acute urinary retention and their creatinine falls spontaneously with insertion of a catheter, they do not necessarily need an ultrasound.

If a patient has had an insult such as profound hypotension, or has AKI in the context of sepsis with a previously normal creatinine, an ultrasound will not add much to the diagnosis unless they fail to recover with time.

However, the above patient warrants ultrasound imaging.

- A. Angiography is not indicated for this patient.
- B. A DMSA scan is not indicated for this patient.
- C. A plain abdominal KUB is less frequently used compared to a CT KUB for stone disease, however this patient has nephritis.
- D. A renal biopsy may be indicated in the future, but an ultrasound should be performed first.
- E. A renal ultrasound scan should be performed in all patients with acute kidney injury, unless a clear treatable cause is identified.

[Q: 1636] OnExamination 2012 - Nephrology

A 66-year-old gentleman is admitted with an exacerbation of chronic congestive heart failure and is treated with intravenous diuretics.

His serum potassium results are shown below.

Admission:

Serum Potassium 4 mmol/L(3.5 - 5.0)

Day 3 of admission:

Serum Potassium 3 mmol/L(3.5 - 5.0)

Which is the best estimate of the total body potassium loss of this patient since admission?

- 1- 1 mmol
- 2- 10 mmol
- 3- 50 mmol
- 4- 75 mmol
- 5- 200 mmol

Answer & Comments

Answer: 5- 200 mmol

This question highlights the importance of potassium distribution within the body. It is a predominantly intracellular ion.

Small reductions in serum potassium are associated with relatively large reductions in total body potassium.

Options A to D are under-estimates of total body potassium and therefore are incorrect and should not be selected.

There is no exact formula to derive the 200mmol. The candidates should recognise that potassium is mainly an intracellular ion (about 95% is intracellular). An approximation for total body loss for potassium is that a drop in 1mmol/L K⁺ of serum potassium is approximately equivalent to a 200mmol K⁺ total body loss. Can I stress that this is an approximation. Given that 200mmol is an approximate calculation, the other options are deliberately chosen to be clearly incorrect (the next highest value being 75 mmol). This question should correlate with clinical experience. It is rare that a large drop in potassium can be corrected with a few tablets with oral potassium and often intravenous replacement at higher doses are required.

Reference:

Gennari FJ. Hypokalaemia. *N Engl J Med.* 1998 Aug 13;339(7):451-8.

[Q: 1637] OnExamination 2012 -
Nephrology

A 50-year-old lady is referred to the renal team with progressive renal impairment and for consideration of renal replacement therapy in the future.

She has a history of type 1 diabetes mellitus (DM) since her teens. Her ultrasound scan shows normally sized kidneys and her urine dip is positive for protein. A renal biopsy is undertaken.

Which of the following findings would be diagnostic of diabetic related kidney injury?

- 1- C4d stain positive
- 2- Congo red stain positive
- 3- Kimmelstiel-Wilson lesion
- 4- Owl's eyes inclusion
- 5- Ring sideroblasts

Answer & Comments

Answer: 3- Kimmelstiel-Wilson lesion

Option C should be selected as it is the only biopsy finding that is specific to diabetic related kidney disease.

Option A is wrong as C4d staining is used for detection of BK virus after renal transplantation.

Congo red stain (option B) should not be selected as this is used to detect amyloidosis.

Option D depicts the biopsy appearance of the Reed-Sternberg cell in Hodgkin's lymphoma or cytomegalovirus (CMV) infection so this is incorrect.

Ring sideroblasts (option E) are peripheral blood film findings in lead toxicity so this is incorrect.

[Q: 1638] OnExamination 2012 -
Nephrology

A 34-year-old man presents with worsening

shortness of breath, wheeze, lethargy and nausea. He has a history of asthma which has been managed by one of your partners with salbutamol and a twice daily combination of a long acting beta-2 agonist and an inhaled steroid inhaler.

On examination his BP is 150/92 mmHg, his pulse is 80 and regular. He has extensive wheeze throughout both lung fields.

Investigations show

Haemoglobin 11.8 g/dl(13.5-18)

White cell count $10.1 \times 10^9/L$

(Eosinophils 30%) (4-10)

Platelets $190 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (134-143)

Potassium 4.9 mmol/l (3.5-5)

Creatinine 189 $\mu\text{mol/l}$ (60-120)

ESR 62 (<10)

Urine Blood++

Protein ++

Which of the following is the most likely diagnosis?

- 1- Alport's syndrome
- 2- Churg-Strauss syndrome
- 3- IgA nephropathy
- 4- Post-streptococcal glomerulonephritis
- 5- Wegener's granulomatosis

Answer & Comments

Answer: 2- Churg-Strauss syndrome

[Q: 1639] OnExamination 2012 -
Nephrology

A 52-year-old man has been referred to the outpatient clinic due to deteriorating renal function.

A diagnosis of adult polycystic kidney disease (APKD) is made.

His family history reveals that his mother died of a stroke at the age of 50, and that his father is still alive. He is concerned regarding the inheritance of the disorder.

What is the probability that his son will inherit it?

- 1- 0%
- 2- 25%
- 3- 50%
- 4- 75%
- 5- 100%

Answer & Comments

Answer: 3- 50%

APKD is an autosomal dominant condition and typically presents between the ages of 30-50.

Patients develop deteriorating renal function and associated hypertension.

As well as renal cysts, they may also have hepatic and berry aneurysms (maternal history may be highly relevant here).

The chance of passing this condition to his son is 50%.

[Q: 1640] OnExamination 2012 - Nephrology

A 30-year-old male presents with oedema and proteinuria.

On examination his blood pressure was 120/70 mmHg.

Investigations reveal:

Creatinine 88 µmol/L (60-110)

Albumin 25 g/L (37-49)

Urinalysis No blood

Protein++++

Urinary protein excretion 7g/24hr (<0.2)

Ultrasound of renal tract: normal right kidney, absent left kidney.

Which is the most appropriate course of action for this patient?

- 1- Albumin transfusion
- 2- Angiotensin converting enzyme (ACE) inhibitor therapy
- 3- High protein diet
- 4- Renal biopsy
- 5- Trial of steroid therapy

Answer & Comments

Answer: 5- Trial of steroid therapy

This patient has nephrotic syndrome, which is a combination of:

Proteinuria (usually > 3g/24 hrs)

Hypoalbuminaemia (<35g/L)

Oedema

Hyperlipidaemia.

The most appropriate course of action here would be to undergo a trial of steroid therapy.

Ideally a renal biopsy would be indicated to determine the cause of the nephrotic syndrome, however as this patient only has one kidney then this would be considered a relative contraindication for such a procedure.

A high protein diet / albumin transfusion would be of little to no benefit - and the latter would need to be salt poor.

ACE inhibitors reduce proteinuria and slow deterioration in glomerular filtration rate (GFR).

In this case given the patient's age he may well have minimal change glomerulonephritis (GN) (commonest in children), which is normally steroid responsive.

In the young adult histological diagnoses are in general: minimal change > mesangiocapillary > FSGS > lupus > membranous > diabetes.

In general steroids are tried first and then second line agents such as cyclosporin and cyclophosphamide are introduced if needed.

[Q: 1641] OnExamination 2012 - Nephrology

A 50-year-old female presents with acute chest pain and dyspnoea.

Examination reveals bilateral ankle oedema with 24 hour urine protein assessment showing 8g/d (<0.2).

Which is the most likely explanation for these findings?

- 1- Factor V Leiden
- 2- Reduced antithrombin III activity
- 3- Reduced concentration of von Willebrand's factor
- 4- Reduced factor VIII
- 5- Reduced fibrinogen concentration

Answer & Comments

Answer: 2- Reduced antithrombin III activity

This patient has developed nephrotic syndrome and appears to have had a thromboembolic event.

The suggestion is that she has had nephritic syndrome before developing the thromboembolism.

Deranged coagulation associated with nephrotic syndrome is a consequence of AT III deficiency, increased fibrinogen and increased factor VIIIc.

[Q: 1642] OnExamination 2012 - Nephrology

Which of the following is a recognised cause of acute renal failure in childhood?

- 1- Alport syndrome
- 2- Burns
- 3- Dermatomyocytis

- 4- Duchenne muscular dystrophy
- 5- Hypothyroidism

Answer & Comments

Answer: 2- Burns

Causes of acute renal failure can be divided into pre-renal, renal and post-renal.

Pre-renal:

Hypovolaemia (gastroenteritis, burns, sepsis, haemorrhage, nephrotic syndrome)

Circulatory failure.

Renal:

Vascular: HUS, vasculitis, embolus, renal vein thrombosis

Tubular: acute tubular necrosis, ischaemic, toxic, obstructive

Glomerular: glomerulonephritis

Interstitial: interstitial nephritis, pyelonephritis

Acute chronic renal failure.

Post-renal:

Obstruction, either congenital or acquired.

Although Alport syndrome is associated with end stage renal failure, this usually progresses gradually so that it occurs in adult life.

Many drugs cause interstitial nephritis.

[Q: 1643] OnExamination 2012 - Nephrology

Which of the following features would be expected in acute tubular necrosis?

- 1- Creatinine clearance would be expected to be normal one year after the initial insult
- 2- Heavy proteinuria on urinalysis
- 3- Red cell casts on urinalysis
- 4- Urine plasma osmolality ratio is more than 1:1

5- Urine sodium concentration greater than 30 mmol/l

Answer & Comments

Answer: 5- Urine sodium concentration greater than 30 mmol/l

Red cell casts suggest nephritis and normalisation of the creatinine clearance occurs in only 40% of cases one year later.

Proteinuria, usually mild, is common with granular casts found on urinalysis.

The urine sodium concentration is typically above 30 mmol/l and osmolality ratio <1:1.

[Q: 1644] OnExamination 2012 - Nephrology

In which of the following patients is an ACE inhibitor contraindicated?

- 1- A 24-year-old woman with type 1 diabetes and microalbuminuria, who wants to start a family
- 2- A 28-year-old woman with reflux nephropathy and hypertension
- 3- A 34-year-old man with essential hypertension and a BMI of 32
- 4- A 34-year-old woman with hypertension and a horseshoe kidney
- 5- A 62-year-old type 2 diabetes patient who has microalbuminuria and a stable creatinine of 210

Answer & Comments

Answer: 1- A 24-year-old woman with type 1 diabetes and microalbuminuria, who wants to start a family

ACE inhibitors are contraindicated in pregnancy. There is an increase in congenital cardiac and neurological abnormalities; and despite the fact this woman has microalbuminuria, use of an ACE inhibitor is not recommended.

In patients with elevated creatinine and microalbuminuria, use of an ACE inhibitor is still a reasonable option, as it has been proven to delay both further deterioration of creatinine and worsening albuminuria.

With respect to essential hypertension and a raised BMI, an ACE inhibitor may be appropriate; other options include a calcium antagonist.

Regarding β -blockers and thiazides, evidence suggests they may increase insulin resistance and risk of diabetes, hence you may choose to avoid them here.

Other contraindications to ACE inhibition include:

- Angio-oedema
- Breast feeding
- Significant renal artery stenosis.

Reference:

New England Journal of Medicine 2006 354:2443-2451

[Q: 1645] OnExamination 2012 - Nephrology

A 63-year-old male recently admitted with sepsis is noted to have a urine output of approximately 20 mls per hour.

The oliguria is more likely to be due to prerenal failure than intrinsic renal failure if which of the following is correct?

- 1- A blood pressure of 150/90 and good tissue perfusion.
- 2- A urine free of red blood cells or casts
- 3- A urine:plasma urea ratio <3
- 4- Urine osmolality <350 mOsm/l
- 5- Urinary sodium >10mmol/l

Answer & Comments

Answer: 2- A urine free of red blood cells or casts

Oliguria is defined as < 400 ml urine/day.

Red cell casts present in:

- Acute glomerulonephritis
- Renal vasculitis
- Accelerated hypertension
- Interstitial nephritis.

Pre-renal failure is renal dysfunction due to hypoperfusion (urinary sodium <20 , urine osmolality >500 , urine/plasma ratio >8 , and urine/plasma creatinine >40).

Acute tubular necrosis is acute renal failure due to circulatory compromise and/or nephrotoxins (urinary sodium >40 , urine osmolality <350 , urine/plasma ratio <3 , and urine/plasma creatinine <20).

[Q: 1646] OnExamination 2012 - Nephrology

A 35-year-old gentleman attends the renal clinic with weight gain and shortness of breath.

Laboratory results show a low albumin, raised cholesterol and urine dipstick shows 3+ protein.

What is the minimum value of protein:creatinine ratio that would be classed as 'nephrotic range' from the answers below?

- 1- 50 mg/mmol
- 2- 100 mg/mmol
- 3- 200 mg/mmol
- 4- 250 mg/mmol
- 5- 300 mg/mmol

Answer & Comments

Answer: 5- 300 mg/mmol

The triad of proteinuria, hypoalbuminaemia and oedema typifies the nephrotic syndrome.

The minimum threshold for proteinuria which is defined as 'nephrotic' is 300 mg/mmol. Hence options A, B, C and D which are below

this level are incorrect and should not be selected.

Reference:

Hull RP, Goldsmith DJ. Nephrotic Syndrome in adults. BMJ. 2008 May 24;336(7654):1185-9

[Q: 1647] OnExamination 2012 - Nephrology

A 17-year-old woman underwent a renal transplant. She was concerned about the effects of long-term ciclosporin treatment.

Which one of the following is a common adverse effect of this drug?

- 1- Alopecia
- 2- Bone marrow depression
- 3- Hepatotoxicity
- 4- Nephrotoxicity
- 5- Paraesthesia

Answer & Comments

Answer: 4- Nephrotoxicity

Ciclosporin causes hypertrichosis rather than alopecia and the most frequent adverse side effect of this drug is nephrotoxicity.

Post renal transplant, the two most common causes of declining renal function are graft rejection and ciclosporin toxicity.

Hepatotoxicity and paraesthesia are less common side effects of the drug.

[Q: 1648] OnExamination 2012 - Nephrology

A 32-year-old male is referred with chronic renal dysfunction and is discovered to have adult polycystic kidney disease (APKD).

His blood pressure is consistently 140-150/90 mmHg.

Which of the following antihypertensives is the most appropriate for the management of this man's blood pressure?

- 1- ACE inhibitor
- 2- Betablocker
- 3- Calcium channel blocker
- 4- Diuretic
- 5- Moxonidine

Answer & Comments

Answer: 1- ACE inhibitor

Autosomal dominant APKD-1 is a relatively common disorder accounting for approximately 8% of cases of end-stage renal disease (ESRD).

"The best drugs for this condition are ACE inhibitors (ie, captopril, enalapril, lisinopril) or angiotensin II receptor antagonist blockers (ie, telmisartan, losartan, irbesartan, candesartan). Calcium channel blockers are not encouraged to be used."

However, although widely used and recommended, there is no evidence that the renin-angiotensin system is affected in the disease.

[Q: 1649] OnExamination 2012 - Nephrology

A 28-year-old female is referred with a three month history of tiredness and weakness.

On examination, pulse is 82 bpm and blood pressure is 128/72 mmHg. No specific abnormalities are evident on examination of the cardiovascular, respiratory, abdominal or neurological systems.

Investigations reveal:

Serum Sodium 142 mmol/l (137-144)

Serum Potassium 3.0 mmol/l (3.5-4.9)

Serum urea 4.2 mmol/l (2.5-7.5)

Serum creatinine 82 µmol/l (60-110)

Serum chloride 73 mmol/l (95-107)

Plasma glucose 5.5 mmol/l (3.0-6.0)

Urinary chloride 60 mmol/l (20-350)

Which of the following is the likely diagnosis?

- 1- Bartter's syndrome
- 2- Conn's syndrome
- 3- Drug ingestion
- 4- Liddle's syndrome
- 5- Non-classical congenital adrenal hyperplasia (CAH)

Answer & Comments

Answer: 3- Drug ingestion

This young woman has hypokalaemia and hypochloraemia.

The normal blood pressure would exclude a diagnosis of Conn's, CAH, or Liddle's syndrome (apparent mineralocorticoid excess). Similarly, drug ingestion associated with hypokalaemia liquorice/carbenoxolone is associated with hypertension (and low urinary chloride less than 20 mmol/l).

Bartter's syndrome is a rare, recessive condition associated with weakness, lethargy and growth retardation and is found in youngsters. Hypokalaemic hypochloraemic alkalosis is seen in the condition but symptoms would be more apparent at a much younger age than this woman.

If Gitelman's syndrome were offered then that would be a better option.

Therefore the most likely diagnosis as the symptoms have arisen only over the last three months and no other features are apparent on examination, is diuretic abuse.

[Q: 1650] OnExamination 2012 - Nephrology

A 16-year-old female presents with ankle swelling four days after having had a sore throat. On examination she had a blood pressure of 125/80 mmHg and ankle oedema. Investigations reveal:

Creatinine 90 µmol/l (60-110)

Albumin 25 g/l (37-49)

24 hour urinary protein 9 g(<0.2)

What is the most likely diagnosis?

- 1- Idiopathic membranous nephropathy
- 2- IgA nephropathy
- 3- Membranoproliferative glomerulonephritis
- 4- Minimal change nephropathy
- 5- Post-streptococcal glomerulonephritis

Answer & Comments

Answer: 2- IgA nephropathy

Idiopathic membranous nephropathy (option A) accounts for 2-5% of cases of nephritic syndrome in children, and 20-30% of cases in adults.

The immune mechanism that leads to the development of membranous nephropathy is unknown. Histologically, it is characterised by diffuse thickening of the glomerular basement membrane (GBM) on light microscopy. On immunofluorescence, the thickening is caused by immune deposits of IgG and C3, on the subepithelial surface of the GBM.

When not idiopathic, it is associated with:

- AI diseases (SLE, rheumatoid arthritis, thyroid disease)
- drugs (gold, penicillamine, captopril)
- malignancy (bronchus, breast, stomach, colon, prostate)
- infections (hep B, syphilis, leprosy, filariasis)
- diabetes mellitus.

Membranoproliferative (or mesangiocapillary) glomerulonephritis (option C) can be classed into three types (I, II, and III) depending on which complement pathway is activated. It is associated with SLE, cryoglobulinaemia with or without hep C, chronic infections (SBE) or with neoplasms. It is not associated acutely with upper respiratory tract infections.

Minimal change nephropathy (option D) is the most common form of nephrotic syndrome in children. The histological findings on light microscopy are normal or small looking glomeruli. On electron microscopy there is effacement of the epithelial cell foot processes over the outer surface of the GBM. It tends to be steroid responsive in children, but over 60% of children will have further relapses. In adults, it is associated with Hodgkin's lymphoma, and other carcinomas.

Post streptococcal GN (option E), as the name implies, occurs 10-14 days after an acute infection. The typical case occurs following infection with group A Lancefield streptococci (β -haemolytic strep, *S. pyogenes*) either causing pharyngitis or skin infections. It is more common in the developing world. The histology shows diffuse proliferative GN, with infiltration by neutrophil polymorphs. The main treatment is eradication of the infection (10/7 course of penicillin) and symptomatic relief of the acute nephritis. The need for dialysis is uncommon, and complete recovery of renal function should occur.

The correct answer is IgA nephritis (option B). IgA nephritis is most common during the second and third decade of life. It commonly occurs within two days of an onset of an upper respiratory tract infection, or less commonly infection of other mucous membranes (e.g. GI, bladder, breast). It should be diagnosed by a renal biopsy, where IgA is seen deposited in the mesangium.

The treatment of IgA nephritis is variable. In a patient with haematuria only, the treatment is conservative. When there is nephrotic range proteinuria (>3 g/day - as in this case) an 8-12 week course of prednisolone should be prescribed. If the proteinuria is <3 g/day an ACE inhibitor can be used. In all patients, careful control of blood pressure should be achieved, by using ACE inhibitors in the first instance, and regular follow up of renal function and urinalysis.

30% of children will have a spontaneous remission within 10 years, but 25% will go on to develop ESRF within 20 years.

[Q: 1651] OnExamination 2012 - Nephrology

An 81-year-old man was admitted with renal failure due to benign prostatic hypertrophy.

His bladder was drained with an urethral catheter followed by a diuresis of more than 3L per day. After two days he became progressively drowsy.

What is the most likely cause for his reduced level of consciousness?

- 1- Hyperglycaemia
- 2- Hypocalcaemia
- 3- Hypomagnesaemia
- 4- Hyponatraemia
- 5- Metabolic acidosis

Answer & Comments

Answer: 4- Hyponatraemia

Amelioration of urinary obstruction and subsequent recovery initially results in a large electrolyte and water loss.

Osmotic cerebral changes precipitated by urinary sodium loss, the major intravascular cation, is the cause of drowsiness.

Hypocalcaemia and hypomagnesaemia may occur as tubular reabsorption is suboptimal in the early stages of recovery, but is unlikely to affect conscious level. Acid-base status should improve after relief of the obstruction.

Hyperglycaemia is not a common complication of recovery from obstructive uropathy.

[Q: 1652] OnExamination 2012 - Nephrology

A 19-year-old female developed pleural effusions, ascites and ankle swelling. Her

blood pressure was 112/76 mmHg.

Investigations revealed:

Serum alanine transferase 17 U/L (5 - 15)

Serum total bilirubin 17 umol/L (1 - 22)

Serum Albumin 21 g/L (34 - 94)

Serum total cholesterol 9.8 mmol/L (<5.2)

What is the next most appropriate investigation?

- 1- Antinuclear antibody
- 2- Pregnancy test
- 3- Prothrombin time
- 4- Serum protein electrophoresis
- 5- Urinary protein estimation

Answer & Comments

Answer: 5- Urinary protein estimation

The low albumin and elevated cholesterol would suggest nephrotic syndrome (more than 4 gram protein/24 hour urine).

Other complications of nephrotic syndrome include:

- Susceptibility to infection
- Thromboses
- Renal failure and
- Protein malnutrition.

The normal BP makes pre-eclampsia unlikely. Besides, the hypercholesterolaemia is the big clue.

[Q: 1653] OnExamination 2012 - Nephrology

A 49-year-old woman has been an inpatient for the past 10 days for treatment of a bronchopneumonia. She has developed the onset of chills, fever, and skin rash over the past two days.

A peripheral blood film reveals eosinophilia. On urinalysis she has ++ proteinuria. There is

no past history of renal disease. Her haemoglobin A1C is normal.

Which of the following diagnoses would be most strongly suggested by these findings?

- 1- Acute serum sickness
- 2- Acute tubular necrosis
- 3- Drug-induced interstitial nephritis
- 4- IgA nephropathy
- 5- Post-streptococcal glomerulonephritis (GN)

Answer & Comments

Answer: 3- Drug-induced interstitial nephritis

The findings are typical of a drug-induced acute interstitial nephritis.

Post-streptococcal GN appears weeks after the acute infection.

Berger's disease (IgA nephropathy) is characterised by haematuria and often follows a 'flu-like' illness.

Eosinophilia is not typical for serum sickness.

[Q: 1654] OnExamination 2012 - Nephrology

Which one of the following is true concerning antidiuretic hormone (ADH)?

- 1- Carbamazepine potentiates its release
- 2- Ethanol potentiates its release
- 3- It circulates in the blood bound to neurohypophysin
- 4- It is a cyclic octapeptide
- 5- It is synthesised in the posterior pituitary

Answer & Comments

Answer: 1- Carbamazepine potentiates its release

ADH is a nonapeptide manufactured in the paraventricular and supra-optic nuclei of the

hypothalamus and released from the posterior pituitary.

It acts on the collecting ducts improving water permeability and hence water retention.

Carbamazepine as well as other agents such as thiazides and selective serotonin reuptake inhibitors (SSRIs) may potentiate its release.

Ethanol usually inhibits release.

Reference:

<http://acbrown.com/kidney/Lectures/RnWatr/RnWatrAntiTrmn.htm>

[Q: 1655] OnExamination 2012 - Nephrology

A 15-year-old girl was seen by her family physician because of increasing lethargy. She had a recent history of the 'flu'.

Biochemistry tests show that she has renal impairment.

Investigations show:

Serum Sodium 140 mmol/L (137-144)

Serum Potassium 4.2 mmol/L (3.5-4.9)

Serum Urea 28 mmol/L (2.5-7.5)

Serum Creatinine 280 µmol/L (60-110)

Her condition does not improve after several weeks on corticosteroid therapy, so a renal biopsy is performed. The biopsy demonstrates the presence of segmental sclerosis of 3 of 10 glomeruli identified in the biopsy specimen.

Immunofluorescence studies and electron microscopy do not reveal evidence for immune deposits.

What is the most appropriate advice to give regarding her condition?

- 1- She has an underlying malignancy
- 2- She may require a renal transplant in 10 years
- 3- She will improve if she loses weight
- 4- She will likely develop a restrictive lung disease

- 5- She will probably improve with additional corticosteroid therapy

Answer & Comments

Answer: 2- She may require a renal transplant in 10 years

The findings in this case point to focal segmental glomerulosclerosis (FSGS). This accounts for approximately 20% of cases of nephrotic syndrome in children and 40% in adults. It is one of the most common primary glomerular disorders causing end-stage renal failure.

Proteinuria is the classic clinical feature, and is typically accompanied by hypoalbuminaemia, hypercholesterolaemia and peripheral oedema. The cardinal feature on renal biopsy is progressive glomerular scarring. Early in the disease course, glomerulosclerosis involves a minority of glomeruli (focal) and only a portion of the glomerular globe (segmental). As the disease progresses more widespread glomerulosclerosis develops. This is due to podocyte injury which leads to effacement of the podocyte foot processes.

80% of causes of FSGS are idiopathic, thought to be mediated by circulating permeability factors. Secondary forms can be familial (due to mutations in specific podocyte genes), viral (HIV-1, parovirus B19, CMV, EBV), drug-induced (heroin, IFN, lithium, pamidronate, anabolic steroids, calcineurin inhibitors), or adaptive (unilateral renal agenesis, hypertension, sickle cell anaemia, vaso-occlusion).

Treatment is aimed at preserving renal function, and inducing remission of proteinuria. Secondary causes should be excluded, as treatment should be targeted at the underlying condition in these cases. Idiopathic cases are treated with renin-angiotensin blockade and dietary sodium restriction initially. If nephrotic syndrome is present, high-dose glucocorticoid therapy

should be initiated and slowly tapered over a period of 3-6 months if a response is seen. If FSGS is glucocorticoid resistant, therapy is with a calcineurin inhibitor.

A significant number of patients with FSGS go on to end-stage renal failure (ESRF). Unfortunately, FSGS recurs in 40% of renal transplants. Risk factors for recurrence include age 6-15y, Caucasian, rapid course to ESRF (<3y), heavy proteinuria prior to transplantation and previous allograft loss. Plasmapheresis has been showed to lead to remission, if used early in the course of recurrence.

[Q: 1656] OnExamination 2012 -
Cardiology

A 55-year-old man presented to the Emergency department with sudden breathlessness.

He is sweaty and obviously short of breath. He is a smoker with a past history of hypertension. There are crackles on inspiration at both his lung bases and his CXR shows upper lobe venous diversion and perihilar shadowing.

His ECG shows sinus tachycardia only and his cardiac enzymes, when they return the next day, are normal. His symptoms resolved quickly with oxygen and furosemide.

Which of the following conditions is the most likely explanation of this presentation?

- 1- Hypertrophic obstructive cardiomyopathy
- 2- Myocardial infarction
- 3- Pheochromocytoma
- 4- Pulmonary embolism
- 5- Renal artery stenosis

Answer & Comments

Answer: 5- Renal artery stenosis

Flash pulmonary oedema in someone with a history of hypertension, especially those suspected of being arteriopathies such as smokers, should raise the possibility of renal artery stenosis.

[Q: 1657] OnExamination 2012 -
Cardiology

Which of the following lipid abnormalities are most likely to be detected in a patient with type 2 diabetes?

- 1- Elevated HDL concentrations
- 2- Elevated LDL concentrations
- 3- Large buoyant LDL molecules
- 4- Reduced triglyceride concentrations

5- Small dense LDL molecules

Answer & Comments

Answer: 5- Small dense LDL molecules

In type 2 diabetes increased cholesteryl ester transfer protein (CETP) activity results in the transfer of triglycerides from very low-density lipoprotein (VLDL) to high-density lipoprotein (HDL) and low-density lipoprotein (LDL).

This results in small dense LDL which is more atherogenic being able to be oxidised more readily and penetrate endothelium and macrophages.

LDL is not typically elevated in type 2 diabetes although there are qualitative changes as indicated above.

HDL is typically low in the patient with type 2 diabetes.

Triglycerides are often elevated with poor glycaemic control.

[Q: 1658] OnExamination 2012 -
Cardiology

A 65-year-old man is admitted to the coronary care unit with an acute inferior myocardial infarction (MI). There are no contraindications to thrombolysis and he receives streptokinase with good resolution of ECG changes.

Three days later examination is normal, with a blood pressure of 134/76 mmHg. Results reveal a total cholesterol of 4.8 mmol/l (<5.2).

Which one of the following drugs does not have good evidence for reducing future morbidity and mortality?

- 1- Aspirin
- 2- Atenolol
- 3- Nifedipine
- 4- Ramipril
- 5- Simvastatin

Answer & Comments

Answer: 3- Nifedipine

Aspirin leads to a 12% reduced risk of death and 31% reduced risk of reinfarction in evidence reviewed by the antiplatelet therapy trialists and also GISSI studies.

Several trials have demonstrated benefit from long term treatment with β -blockers, by reducing the incidence of recurrent MI, and death from all causes.

Numerous trials have shown benefit from angiotensin converting enzyme (ACE) inhibitor therapy post MI in those with and without evidence of left ventricular impairment.

The 4S (Scandinavian Simvastatin Survival Study) demonstrated a benefit from lowering cholesterol with simvastatin in patients with coronary disease.

There is no evidence to support a beneficial effect of nifedipine post- MI.

[Q: 1659] OnExamination 2012 - Cardiology

A 60-year-old man with diabetes presents to clinic for advice on prevention of a further heart attack after having sustained a myocardial infarction five years previously.

He takes metformin 500 mg tds, bendroflumethiazide 2.5 mg daily and aspirin 150 mg daily. His body mass index was 33.5 kg/m², with a pulse of 82 beats per minute regular and a blood pressure of 152/92 mmHg. His cholesterol concentration is 3.3 mmol/l (<5.5).

What is the most appropriate strategy for this patient?

- 1- 24 hour ambulatory ECG
- 2- Atorvastatin
- 3- Increase aspirin from 150 mg to 300 mg daily
- 4- Orlistat

5- Ramipril

Answer & Comments

Answer: 5- Ramipril

The most appropriate strategy for secondary prevention would involve further blood pressure reduction with an angiotensin converting enzyme inhibitor (ACEi), which would not only reduce cardiovascular (CV) risk as suggested by the HOPE study but also reduce microvascular risk as revealed by UKPDS.

The NCEP ATPIII criteria suggest a cholesterol less than 4, but this patient already has a low cholesterol and would not benefit as much from the addition of a statin.

The increase of aspirin from 150 to 300 mg would offer no added advantage.

Orlistat is used under specific criteria for weight reduction and has, as yet, not been shown to reduce CV risk in type 2 diabetes mellitus (T2DM).

There is no reason here for a 24 hour tape.

[Q: 1660] OnExamination 2012 - Cardiology

In a patient presenting with aortic stenosis (AS), *which of the following findings would be most helpful in establishing a diagnosis of congenital bicuspid valve as the aetiology?*

- 1- Age
- 2- Calcified leaflets
- 3- Commissural fusion on ECHO
- 4- Negative history for rheumatic fever
- 5- Systolic ejection click

Answer & Comments

Answer: 5- Systolic ejection click

Age and calcified aortic root suggest calcific aortic valvular disease.

Rheumatic AS results from fibrosis of the leaflets and fusion of the commissures.

An ejection click or ejection sound, best heard at the apex, implies that the site of the stenosis is mostly valvular and of congenital origin, that is, bicuspid valvular disease.

[Q: 1661] OnExamination 2012 - Cardiology

A patient presents with atrial fibrillation which later reverts to sinus rhythm.

In which of the following circumstances is the patient more likely to remain in sinus rhythm?

- 1- Age more than 75-years-old
- 2- Been commenced on warfarin
- 3- Left atrium size greater than 6 cm on ECHO
- 4- Short history of AF
- 5- Ventricular rate on presentation of 130 bpm

Answer & Comments

Answer: 4- Short history of AF

The patient with very recent onset of atrial fibrillation is more likely to stay in sinus rhythm.

Atrial fibrillation in older patients is more likely to be associated with structural heart disease.

Anticoagulation should have no effect on the risk of paroxysmal atrial fibrillation.

An enlarged left atrium is unlikely to remain in sinus rhythm.

Those presenting with a relatively slow ventricular rate and, especially if they are not on β -blockers, calcium antagonists or digoxin, are likely to have chronic atrial fibrillation.

[Q: 1662] OnExamination 2012 - Cardiology

A 52-year-old sales representative is admitted

with an inferior myocardial infarction (MI). He receives thrombolysis and makes an uneventful recovery.

He is discharged on atenolol, aspirin and atorvastatin.

He enquires how long after his MI must he wait before he is able to drive?

- 1- One week
- 2- Two weeks
- 3- Four weeks
- 4- Three months
- 5- Six months

Answer & Comments

Answer: 3- Four weeks

The DVLA is quite clear on this issue. He must wait at least four weeks after his MI before he is able to drive.

Similarly, patients undergoing surgical revascularisation must also wait four weeks.

If he was admitted with angina and underwent percutaneous transluminal coronary angioplasty (PTCA) then he should wait one week.

[Q: 1663] OnExamination 2012 - Cardiology

According to Starling's law, when the end-diastolic volume increases, resulting in myocardial stretch, *how does the heart maintain an adequate cardiac output?*

- 1- Increases capillary permeability
- 2- Increases central vasodilation to redistribute the fluid to other organs
- 3- Increases myocardial contraction
- 4- Increases peripheral vasodilation to reduce strain on the heart
- 5- Increases urine production to reduce intravascular volume

Answer & Comments

Answer: 3- Increases myocardial contraction

The cardiac output (CO) is the volume of blood being pumped by the heart in one minute, and must be maintained within a narrow range to allow normal function. It is a reflection of how well the body is being perfused, and therefore how well the body can work (perfusion enables energy production). It can be calculated from the stroke volume (SV) and heart rate (HR) as follows:

$$CO = HR \times SV$$

Stroke volume, (the amount of blood pushed out of the left ventricle on each pump of the heart), is determined by many factors which are summed up in (Frank-) Starling's law. This law states that when the myocardium stretches due to blood pooling, the force of contraction increases, to preserve the stroke volume, and thus the cardiac output.

The diagram below shows that the ideal operating point of the heart occurs when cardiac output and venous return are equal (that is, blood in equals blood out).

As end-diastolic volume increases from this point, there is greater myocardial stretch and a greater rebound contraction. The result is that cardiac output can increase but only up to a certain point. After this, cardiac output cannot increase further despite excessive end-diastolic pressure.

(Diagram of showing the physiological relationship between the Starling Law of the heart and venous return pressure and volume. Public Domain license: http://en.wikipedia.org/wiki/File:Starling_RAP_combined.svg)

This increase in rebound contraction involves the sarcomere - the basic muscle unit of the myocardium (see diagram below). When required, the sarcomere can stretch to allow more interaction between its branches (actin and myosin filaments). At 2.2 micrometers, the number of interactions is maximal. If the heart continues to stretch the sarcomeres lengthens to over 2.2 micrometers, and the number of interactions decrease. This results in less effective contractions of the heart overall which can eventually lead to heart failure.

(Sarcomere. GNU Free License. Taken from: <http://en.wikipedia.org/wiki/File:Sarcomere.svg>)

[Q: 1664] OnExamination 2012 - Cardiology

A 52-year-old housewife presents to the hypertension clinic with hypertension that has proved difficult to control.

Her general practitioner has started ramipril 1.25 mg, amlodipine 5 mg, bisoprolol 2.5 mg and bendroflumethiazide 2.5 mg. Her systolic blood pressure is 152 mmHg, and it has consistently ranged 150 - 160 mmHg.

The urine dipstick is normal. Renal function and electrolytes are normal. Her ECG showed borderline left axis deviation but is otherwise normal in rhythm and complexes, and a subsequent echocardiogram demonstrates good ejection fraction with no significant systolic or diastolic impairment.

What is the best treatment option for this patient?

- 1- Add spironolactone 2.5 mg
- 2- Add isosorbide mononitrate 25 mg BD
- 3- Increase bendroflumethiazide to 5 mg
- 4- Increase ramipril to 2.5 mg
- 5- Venesection

Answer & Comments

Answer: 4- Increase ramipril to 2.5 mg

Use of multiple antihypertensives at low doses is preferable to having fewer tablets at higher doses, in view of the synergistic effectiveness of targeting several underpinning mechanisms of hypertension.

The ramipril dose can be increased, as the renal function is normal and 1.25 mg is a modest dose.

Repeat renal function is advised following any increase in ACE inhibition.

Spironolactone is indicated in heart failure, at the higher dose of 25 mg.

Other indications include portal hypertension-induced abdominal ascites, nephrotic syndrome and hyperaldosteronism syndrome. Renal function is normal, making the possibility of hyperaldosteronism (which features a hypokalaemic alkalosis) remote.

Nitrates are indicated in angina, as an adjuvant in heart failure, but not solely for hypertension in view of tolerance to their antihypertensive action.

The echocardiogram excludes systolic and diastolic heart failure, and thus the indication for spironolactone or nitrates.

Bendroflumethiazide above the standard dose of 2.5 mg OD has no beneficial effects in blood pressure profile and runs an increased risk of side effects (exacerbating gout, diabetes, lupus and renal impairment).

Therapeutic venesection has no role in the management of chronic hypertension.

Other antihypertensive options include adding another diuretic (metolazone or bumetanide or two potent loop diuretics), alpha blocker (doxazosin) or beta blockers.

Reference:

NICE Clinical Guideline 34: Hypertension. National Institute for Health and Clinical Excellence, London (2006).

[Q: 1665] OnExamination 2012 - Cardiology

A 59-year-old office worker is diagnosed with essential hypertension, following sequential blood pressure readings in the range of 150 - 162 / 85 - 92.

She has no other medical issues, and is started on an ACE inhibitor, which is uptitrated over the following year to a dose of ramipril 5 mg OD. At her next consultation she reports a concerted effort to address lifestyle factors over the preceding year, leading to substantial weight loss. She has also given up occasional smoking since her retirement, and is currently asymptomatic.

On clinical examination the blood pressure is 126 / 78. BMI 22.4. The apex is undisplaced. Fasting blood tests are as follows:

Serum Sodium 141[132 - 144 mmol/l]

Serum Potassium 4.2[3.5 - 5.0 mmol/l]

Urea 4.7[2.5 - 7.5 mmol/l]

Creatinine 74[50 - 120 µmol/l]

Bilirubin 8[2 - 17 µmol/l]

Alanine aminotransferase 23[5 - 40 U/l]

Alkaline phosphatase 70[50 - 160 U/l]

Albumin 32[35 - 55 g/l]

Total protein 86[62 - 80 g/l]

C Reactive protein 4[10mg/l]

ECG normal sinus rhythm

What is the next step in management of this patient's blood pressure?

- 1- 24 hour urinary protein
- 2- Add aspirin 75 mg for primary prevention
- 3- Encourage continued weight loss and recheck blood pressure in a year
- 4- Myeloma screen
- 5- Reduce ramipril to 1.25 mg

Answer & Comments

Answer: 5- Reduce ramipril to 1.25 mg

The patient has closely adhered to advice on lifestyle modification with great success.

Her blood pressure has normalised in the absence of precipitating environmental factors, providing an opportune moment to trial withdrawal of pharmacotherapy. She is at low cardiovascular risk, and the dose of ACE inhibitor should be tapered with a view to stopping it altogether.

Aspirin is not advised for primary prevention of ischaemic heart disease in a low-risk population, as the risk-benefit ratio is unconvincing in this population. Continued weight loss may be beneficial to her overall health, but there is little room for improvement in her blood pressure so there is nothing against reducing her tablets now.

Note the borderline abnormalities in protein and albumin levels. A high protein level in the presence of low albumin level may indicate a surreptitious monoclonal gammopathy, and considering myeloma is advisable at this stage (though it is not part of management of blood

pressure, and therefore an incorrect answer to this question).

Serum calcium, immunoglobulins, electrophoresis and early morning urinary electrophoresis / Bence Jones protein assay complete a myeloma screen, with skeletal survey only being carried out should these be suggestive of myeloma.

A urine dipstick rather than 24 hour protein collection would be more advisable in the first instance as a negative test would exclude significant renal protein losses.

Reference:

Barnett H et al. *BMJ* 2010; 340: 920 - 1: editorial against the use of aspirin in primary prevention. NICE Clinical Guideline 34: Hypertension. National Institute for Health and Clinical Excellence, London (2006).

[Q: 1666] OnExamination 2012 - Cardiology

A 70-year-old woman has failed two previous attempted cardioversions for atrial fibrillation. She has previously been echoed which revealed left atrial enlargement and mild LV dysfunction.

She has a history of a previous myocardial infarction four years earlier, and currently takes ramipril 10 mg, furosemide 40 mg, atorvastatin 40 mg, and aspirin 75 mg.

On examination her BP is 135/70 mmHg, with a pulse of 100 in atrial fibrillation (AF). She has bibasal crackles consistent with heart failure and there is mild bilateral pitting oedema.

Investigations show:

Hb 11.9 g/dl (11.5-16.5)

WCC $6.1 \times 10^9/L$ (4-11)

PLT $221 \times 10^9/L$ (150-400)

Na 139 mmol/l (135-146)

K 4.4 mmol/l (3.5-5)

Cr 131 $\mu\text{mol/l}$ (79-118)

Which of the following would be the most appropriate agent in this patient for rate control of her AF?

- 1- Amiodarone
- 2- Amlodipine
- 3- Atenolol
- 4- Bisoprolol
- 5- Digoxin

Answer & Comments

Answer: 4- Bisoprolol

This patient has a history of ischaemic heart disease and heart failure present on clinical examination. As such, she is likely to gain a potential outcome benefit from a selective β -blocker such as bisoprolol, which has demonstrated outcomes from the CIBIS 2 study.

Digoxin would be a reasonable alternative for rate control and also has some benefit in terms of symptom relief for heart failure, but would not be the first choice, especially in view of her mild renal impairment.

Amlodipine has no significant effect with respect to rate control in AF, and amiodarone is most appropriate for chemical cardioversion.

[Q: 1667] OnExamination 2012 - Cardiology

A 24-year-old woman develops infective endocarditis involving the aortic valve.

She receives a porcine bioprosthesis because of her desire to have children and not to take anticoagulant medication.

After ten years, she must have this prosthetic valve replaced.

Which of the following pathological findings in the bioprosthesis has most likely led to the need for replacement?

- 1- Calcification with stenosis

- 2- Dehiscence
- 3- Infective endocarditis
- 4- Strut failure
- 5- Thrombosis

Answer & Comments

Answer: 1- Calcification with stenosis

The bioprosthesis has the advantage of not requiring anticoagulation, but it does not wear well with time, and typically must be replaced within five to 10 years.

[Q: 1668] OnExamination 2012 - Cardiology

A 25-year-old female who is 20 weeks pregnant with her first child is admitted with palpitations.

The ECG reveals a supraventricular tachycardia (SVT) and this self terminates 20 minutes after admission. Subsequently she has further runs of symptomatic SVT.

What would be the most appropriate treatment for this patient's paroxysmal supraventricular tachycardia?

- 1- Amiodarone
- 2- Disopyramide
- 3- Flecainide
- 4- Metoprolol
- 5- Verapamil

Answer & Comments

Answer: 4- Metoprolol

Tachyarrhythmias may increase during pregnancy although the causes are not entirely clear.

Regarding the termination of acute SVT, adenosine appears to be safe in pregnancy. In the case of the prevention of recurrent SVT then verapamil or β -blockers have data supporting their use.

Current AHA/EHA criteria for the treatment of SVTs in pregnancy do suggest using metoprolol (level of evidence 1B) rather than verapamil (C), although they recommend avoiding the former in the first trimester.

[Q: 1669] OnExamination 2012 - Cardiology

You wish to calculate a patient's ejection fraction as the patient complains of dyspnoea.

Which of the following echocardiographic measures would be mandatory?

- 1- Aortic valve peak velocity
- 2- Left ventricular end diastolic diameter
- 3- M-mode of the aortic valve
- 4- M-mode of the mitral valve
- 5- Pulse wave of mitral inflow

Answer & Comments

Answer: 2- Left ventricular end diastolic diameter

One way of measuring ejection fraction is estimated by the ratio between the M-mode readings of the left ventricular end diastolic diameter divided by the end systolic diameter.

[Q: 1670] OnExamination 2012 - Cardiology

A 62-year-old male undergoes cardioversion for idiopathic atrial fibrillation (AF). Post-procedure he was shown to be in sinus rhythm.

Medication at admission included warfarin, digoxin and atenolol, which he had been taking for the last six weeks.

Which of the following agents should he continue to take until he is seen in clinic in six weeks time?

- 1- Aspirin
- 2- Atenolol
- 3- Digoxin

- 4- Sotalol
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

This patient has undergone successful cardioversion for idiopathic AF and needs to remain on warfarin as his risk of further thromboembolism, due to the fact that his atria are now contracting, normally remains high up until six weeks after achieving sinus rhythm.

Digoxin is not required post-procedure as neither it, nor atenolol, maintains sinus rhythm.

Aspirin is not as good as warfarin in preventing thromboembolic disease.

Sotalol, like amiodarone, is good at chemical cardioversion and maintaining SR but its role post-cardioversion is uncertain.

[Q: 1671] OnExamination 2012 - Cardiology

A 78-year-old female is referred by her GP with high blood pressure. Over the last three months her blood pressure is noted to be around 180/80 mmHg. She has a body mass index of 25.5 kg/m² and is a non-smoker.

There are no features to suggest a secondary cause for her hypertension.

Which of the following is the most appropriate treatment for her blood pressure?

- 1- Alpha-blocker
- 2- Angiotensin blocker
- 3- Angiotensin converting enzyme (ACE) inhibitor
- 4- Beta-blocker
- 5- Calcium channel blocker

Answer & Comments

Answer: 5- Calcium channel blocker

This patient has isolated systolic hypertension (systolic BP >160 and diastolic BP <90 mmHg) which is the typical hypertension in the elderly population and is associated with a greater risk than combined systolic/diastolic hypertension.

Based upon studies such as SHEP and Syst-Eur, guidelines suggest treatment with either calcium antagonists or diuretics.

[Q: 1672] OnExamination 2012 - Cardiology

A 56-year-old male with left ventricular systolic dysfunction was dyspnoeic on climbing stairs but not at rest. The patient was commenced on ramipril and furosemide.

Which one of the following drugs would improve the patient's prognosis?

- 1- Amiodarone
- 2- Amlodipine
- 3- Bisoprolol
- 4- Digoxin
- 5- Nitrate therapy

Answer & Comments

Answer: 3- Bisoprolol

This patient has NYHA stage II heart failure.

Studies such as CIBIS-II and MERIT-HF reveal that β -blockers significantly reduce morbidity and mortality in heart failure.

[Q: 1673] OnExamination 2012 - Cardiology

A child is brought to the Emergency department by his parents after a three month history of blue lips and breathlessness.

You arrange urgent admission and follow up the case on your next shift. You call the

paediatric SHO to find out about the child. She tells you he underwent a transthoracic echocardiogram and it demonstrated displacement of the tricuspid valve towards the apex, a small 'atrialised' and hypoplastic RV and an ASD. You go to the ward to see the patient and look in his notes. You review his ECG.

Based on the likely diagnosis, which ECG finding is most likely to be present?

- 1- Left axis deviation
- 2- Left bundle branch block
- 3- Right bundle branch block
- 4- Type A Wolff-Parkinson-White (WPW) pattern
- 5- Type B Wolff-Parkinson-White pattern

Answer & Comments

Answer: 3- Right bundle branch block

The echo findings in this child are characteristic for Ebstein's anomaly.

This congenital heart defect predominantly affects the right heart and disrupts the right bundle branch, leading to a right bundle branch block pattern on ECG.

Type B WPW is seen in around 15% of cases.

Other ECG findings include evidence of right atrial hypertrophy.

[Q: 1674] OnExamination 2012 - Cardiology

Which ONE of the following is associated with Marfan's syndrome?

- 1- Autosomal recessive inheritance
- 2- increased upper:lower body ratio
- 3- Mental retardation
- 4- Pulmonary stenosis
- 5- Retinal detachment

Answer & Comments

Answer: 5- Retinal detachment

Marfan's syndrome is an autosomal dominant condition associated with ocular abnormalities such as upwards lens dislocation and retinal detachment.

Aortic regurgitation may be a finding and aneurysmal dilatation is a feature. Upper to lower body ratio (head to symphysis pubis : symphysis pubis to toes) is decreased in Marfan Syndrome.

[Q: 1675] OnExamination 2012 - Cardiology

A 26-year-old man is found to have hypertrophic obstructive cardiomyopathy.

A 24 hour ECG recording reveals runs of non-sustained ventricular tachycardia.

He has had three episodes of syncope in the last two years.

Which of the following is the most appropriate management plan for this man?

- 1- Amiodarone
- 2- AV node ablation
- 3- Implantable cardioverter defibrillator (ICD)
- 4- Permanent pacemaker
- 5- Sotalol

Answer & Comments

Answer: 3- Implantable cardioverter defibrillator (ICD)

When the risk level for sudden cardiac death (SCD) is judged by contemporary criteria to be unacceptably high and deserving of intervention, the ICD is the most effective and reliable treatment option available, harbouring the potential for absolute protection and altering the natural history of this disease in some patients.

[Q: 1676] OnExamination 2012 - Cardiology

A 70-year-old known hypertensive and diabetic patient presents with dyspnoea on moderate exertion.

On examination he is pale, pulse rate is 98/min regular, BP is 160/70 mmHg and there are fine basal crepitations in the lungs. ECG showed left ventricular hypertrophy and renal functions were slightly deranged.

What is the most appropriate treatment for cardiac failure in this patient?

- 1- ACE-I alone
- 2- Furosemide alone
- 3- Spironolactone, ramipril and aspirin
- 4- Spironolactone, ramipril and carvedilol
- 5- Spironolactone, ramipril and digoxin

Answer & Comments

Answer: 4- Spironolactone, ramipril and carvedilol

All patients with cardiac failure should be on an angiotensin-converting enzyme inhibitor (ACE-I) if there is no contraindication.

In this patient there will be an additional benefit for hypertension and prevention of diabetic nephropathy.

Once stable β blocker should be added. It is proven that cardioselective β blockers have important beneficial effects especially in patients with underlying coronary artery disease.

The randomised Aldactone evaluation study (RALES) trial showed 30% reduction in mortality when spironolactone (25 mg) was added to the standard therapy.

Digoxin is used in heart failure with atrial fibrillation. As it is a weak positive inotrope, its role in heart failure with sinus rhythm may be best reserved if the patient remains symptomatic despite optimal therapy.

Old people with renal impairment are at increased risk of toxicity.

[Q: 1677] OnExamination 2012 - Cardiology

A 65-year-old man has an ejection systolic murmur and narrow pulse pressure on clinical examination.

There is no history of chest pain, breathlessness or syncope.

An ECHO confirms aortic stenosis and shows an aortic valve gradient of 40 mmHg. There is good left ventricular function.

Which of the following management options is the most appropriate choice in this case?

- 1- Anticoagulation
- 2- Aortic valvuloplasty
- 3- Cardiology outpatient review
- 4- Routine aortic valve replacement
- 5- Urgent aortic valve replacement

Answer & Comments

Answer: 3- Cardiology outpatient review

Indications for surgery in aortic stenosis include a gradient of 50 mmHg or more, or associated symptoms such as syncope, breathlessness and episodes of pulmonary oedema.

This patient should be monitored in cardiology clinic so that a decision on the timing of valve surgery can be made.

[Q: 1678] OnExamination 2012 - Cardiology

A 73-year-old male is referred with palpitations.

On 24 hour ambulatory ECG monitoring he is shown to have paroxysmal atrial fibrillation and is treated with amiodarone.

Through blockade of which of the following receptors is the antiarrhythmic effect of amiodarone most attributed?

- 1- Alpha receptors
- 2- Beta receptors
- 3- Calcium channels
- 4- Potassium channels
- 5- Sodium channels

Answer & Comments

Answer: 4- Potassium channels

Amiodarone is a class III antiarrhythmic and as such is used in many supra- and ventricular arrhythmias.

Its antiarrhythmic effects are due mostly to the inhibition of the rapid component of the delayed potassium rectifier IKr channel (as with sotalol) but also an effect on the slow component.

However, it is also recognised to have mild alpha-blocking effects, beta-blocking effects and calcium channel blocking effects although these are less responsible for the antiarrhythmic effects.

[Q: 1679] OnExamination 2012 - Cardiology

A 70-year-old female is reviewed in clinic after having had an anterior MI. Her echo reveals some left ventricular impairment.

You are contemplating the addition of a beta-blocker to current therapy which consists of bendroflumethiazide, aspirin and simvastatin.

Which of the following beta-blockers should be avoided?

- 1- Bisoprolol
- 2- Carvedilol
- 3- Metoprolol
- 4- Propranolol
- 5- Sotalol

Answer & Comments

Answer: 5- Sotalol

Sotalol may prolong the QT interval and leads to a risk of ventricular arrhythmias. This can be a particular risk in individuals with hypokalaemia.

The thiazide diuretic bendroflumethiazide predisposes to hypokalaemia, due to its action on inhibiting potassium reabsorption in the distal tubules of the nephrons.

[Q: 1680] OnExamination 2012 - Cardiology

Concerning complete atrioventricular septal defects which one of the following statements is true?

- 1- Are seen frequently in patients with trisomy 21
- 2- Frequently have aortic valve (AV) insufficiency
- 3- Have a normal mitral valve structure
- 4- Include a coronary sinus atrial septal defect (ASD)
- 5- Include a perimembranous ventricular septal defect

Answer & Comments

Answer: 1- Are seen frequently in patients with trisomy 21

Partial AV canal defects or ostium primum ASDs are seen in Down syndrome.

Sinus venous defects seem to be rare in Down syndrome

Possibly 50% of children with Down syndrome have a cardiac defect.

[Q: 1681] OnExamination 2012 - Cardiology

A 21-year-old woman has a history of palpitations and light headedness. ECG shows

short PR interval and inferior Q waves.

Her symptoms improve with atenolol 25 mg/day but she has had two short episodes of similar symptoms in the previous 24 hours.

What is the long term management of choice?

- 1- Anticoagulation
- 2- Oral amiodarone
- 3- Oral digoxin
- 4- Increase the dose of atenolol
- 5- Radiofrequency ablation

Answer & Comments

Answer: 5- Radiofrequency ablation

Wolff-Parkinson-White (WPW) syndrome can be associated with negative delta waves in II, III and aVF.

The long term management of choice is ablation of the accessory pathway.

[Q: 1682] OnExamination 2012 - Cardiology

A 35-year-old woman presented with a history of intermittent light-headedness. Clinical examination and 12 lead ECG were normal.

Which of the following, if present on a 24 hour Holter ECG tracing, would be the most clinically important?

- 1- Atrial premature beats.
- 2- Profound sleep-associated bradycardia.
- 3- Supraventricular tachycardia (SVT).
- 4- Transient Mobitz type 1 atrioventricular block.
- 5- Ventricular premature beats.

Answer & Comments

Answer: 3- Supraventricular tachycardia (SVT).

SVT commonly presents with palpitations but occasionally is associated with light-headedness.

I really struggled with this question. I think it is what examiners refer to as a discriminatory question or basically one with no right answer.

The problem is that intuitively SVT is the most common arrhythmia in this age group and can be associated with light-headedness but as you know significant SVT commonly presents with palpitations - however, there is no mention of palpitations.

The word "profound", preceding sleep-associated bradycardia is confusing; are they alluding to the fact that this woman has sick sinus and significant bradycardia has only manifested itself in her sleep? Is this more than just normal sleep associated bradycardia? I do not think that is the right answer though.

Then there is D. Wenkebach is almost always asymptomatic but what is a 35-year-old doing with Mobitz type I (it is commonly seen in athletes - Dean Jenkins)?

We had a straw poll here at cardiology and decided in the end the right answer is C, which I agree with.

[Q: 1683] OnExamination 2012 - Cardiology

A 75-year-old man presents with severe central crushing chest pain. ECG shows evidence of an inferior myocardial infarction (MI). He receives primary stenting to the proximal right coronary artery

Four hours after initial presentation, he starts feeling dizzy and breathless. His pulse is 30 bpm regular, BP 70/50 mmHg. Heart sounds are soft and chest clear to auscultation. ECG shows 2:1 AV block with broad QRS and T wave inversion inferiorly. IV atropine was administered but had no effect.

What is the next most important treatment?

- 1- Emergency insertion of a permanent pacemaker

- 2- Emergency temporary transvenous pacing wire
- 3- IV dopamine
- 4- IV isoprenaline
- 5- Monitor his progress

Answer & Comments

Answer: 2- Emergency temporary transvenous pacing wire

This patient has had an inferior MI which is commonly associated with conduction abnormalities. He now develops heart block which leaves him bradycardic, symptomatic and with a low BP, so just monitoring progress is not appropriate.

Isoprenaline is contraindicated in acute MI due to its positive inotropic effects and arrhythmogenic potential. IV dopamine is an inotrope which will not treat conduction block.

A temporary wire would deal with the situation until the inferior MI has fully resolved. Conduction block can recover in the next few days so a permanent pacemaker may not be required

[Q: 1684] OnExamination 2012 - Cardiology

Which of the following is not a component of the cardiac electrical conduction pathway?

- 1- Atrioventricular node
- 2- Bundle of His
- 3- Purkinje fibres
- 4- Sarcomere
- 5- Sinoatrial node

Answer & Comments

Answer: 4- Sarcomere

To enable the circulation of blood through the heart, and through the body, the heart

requires coordinated muscular contraction. This is made possible because of the electrical conduction pathway of the heart. An understanding of the anatomy and physiology of the conducting system is important to allow the interpretation of ECGs and the diagnosis of arrhythmias.

The electrical signal starts off at the sinoatrial node (SAN); it then passes to the atrioventricular node (AVN) depolarising the left and right atrium whilst it passes through (thus enabling contraction).

At the atrioventricular node, a short delay occurs, allowing the atrium to start relaxing, before the impulse travels down the bundle of His, and divides along the left and right bundle branches, where it causes depolarisation of the right and left ventricles, and thus ventricular contraction.

Once the atrium and ventricle have repolarised, the cycle starts anew.

1. Sinoatrial node
2. Atrioventricular node
3. Bundle of His
4. Left bundle branch

5. Left posterior fascicle
6. Left anterior fascicle
7. Left ventricle.
8. Ventricular Septum
9. Right Ventricle
10. Right Bundle Branch

Reference:

J. Heuser. *Electrical Conduction of the Heart*. Creative Commons license. Taken from http://en.wikipedia.org/wiki/File:RLS_12blauLeg.png

[Q: 1685] OnExamination 2012 - Cardiology

A 24-year-old man is admitted from a soccer match by ambulance. He collapsed during the game. Medical staff who attended the scene found him to be in VT and he was shocked by the automated defibrillator which was at the stadium.

By the time he reaches the emergency department he is beginning to regain consciousness and is complaining of a sore chest from where he was shocked. On examination his blood pressure is elevated at 145/82 mmHg. He has a double apical impulse and a mid systolic murmur.

Investigations show

Haemoglobin 13.4 g/dl (13.5-18)

White cell count $5.6 \times 10^9/L$ (4-10)

Platelets $201 \times 10^9/L$ (150-400)

Sodium 141 mmol/l (134-143)

Potassium 4.8 mmol/l (3.5-5)

Creatinine 105 $\mu\text{mol/l}$ (60-120)

ECG LVH with anterior Q waves

Which of the following is the most likely diagnosis?

- 1- Brugada syndrome
- 2- HOCM
- 3- Long QT

- 4- Post viral cardiomyopathy
5- Wolff-Parkinson-White syndrome

Answer & Comments

Answer: 2- HOCM

The double apical impulse, mid systolic murmur and ECG appearance is typical of that seen with hypertrophic obstructive cardiomyopathy (HOCM). It is the commonest cause of genetic cardiac disease, affecting 1 in 500 to 1 in 1000 adults.

Patients present with symptoms of dyspnoea, angina and syncope due to outflow obstruction, although sudden cardiac death is usually related to fatal ventricular arrhythmia.

Implantable defibrillators are now the treatment of choice in patients who suffer ventricular arrhythmias.

Patients with Brugada syndrome present with ventricular arrhythmias, but have structurally normal hearts.

[Q: 1686] OnExamination 2012 - Cardiology

Which of the following regarding the anatomy of the heart is true?

- 1- The aortic valve is tricuspid
- 2- The ascending aorta is entirely outside the pericardial sac
- 3- The left atrial appendage is identified readily by transthoracic echocardiography
- 4- The right atrium is posterior to the left atrium
- 5- The right branch of the pulmonary artery lies anterior to the ascending aorta

Answer & Comments

Answer: 1- The aortic valve is tricuspid

The right branch of the pulmonary artery lies posterior to the ascending aorta.

The ascending aorta lies completely within the pericardium as does the pulmonary trunk.

The left atrium is the most posterior chamber of the heart; the right atrium is just anterior and to the right of the left atrium.

The left atrial appendage is not readily seen on transthoracic echocardiography and requires transoesophageal echocardiography.

[Q: 1687] OnExamination 2012 - Cardiology

A 36-year-old patient with hypertension presents following an unplanned pregnancy.

Her blood pressure has been modestly controlled on amlodipine 5 mg and ramipril 2.5 mg over the past five years, with the diagnosis of essential hypertension following a thorough screen for secondary causes. She wishes to proceed with the pregnancy. Her current blood pressure is 135/85 mmHg.

What next step would you take?

- 1- 24 hour urine collection for protein
- 2- ECG to screen for evidence of end organ damage
- 3- Stop amlodipine
- 4- Stop ramipril
- 5- Switch to methyldopa

Answer & Comments

Answer: 4- Stop ramipril

Ramipril, other ACE inhibitors and angiotensin II receptor blockers have an increased risk of congenital abnormalities in pregnancy. The priority is to stop either of these drugs early in pregnancy, overriding any need to screen for end organ damage with an ECG.

Little information is available on the effects of amlodipine on the fetus, and its use may continue if the blood pressure mandates it.

Methyldopa is a drug used in pre-eclampsia.

Proteinuria is an important finding in pregnancy, though the screening tool of urine dipstick is often followed by a urinary protein/creatinine ratio rather than a formal 24 hour collection.

Target blood pressures in chronic maternal hypertension are 150/100 mmHg, or 140/90 mmHg in the context of end organ damage.

Reference:

NICE Clinical Guideline 107: Hypertension in pregnancy. National Institute for Health and Clinical Excellence, London (2010).

[Q: 1688] OnExamination 2012 - Cardiology

A 29-year-old female attends the emergency department complaining of acute onset of palpitations. She is attached to a cardiac monitor and her pulse rate is 180 bpm.

She is warm and well perfused, her BP is 135/80 mmHg, respiratory rate 20/min, oxygen saturation 100% on air and on auscultation her chest is clear with no evidence of cardiac failure.

ECG shows a narrow complex tachycardia. Carotid massage and Valsalva manoeuvre have failed to attenuate the rhythm disturbance.

What is the appropriate initial management?

- 1- DC cardioversion
- 2- IV adenosine
- 3- IV amiodarone
- 4- IV digoxin
- 5- IV magnesium

Answer & Comments

Answer: 2- IV adenosine

This patient has a narrow complex supraventricular tachycardia.

From history and examination she is not haemodynamically compromised and,

therefore, initial management would be intravenous adenosine in the absence of contraindication (for example, asthma) in order to create a transient conduction delay.

This may terminate the tachycardia, or cause a slowing in rate to allow identification of the underlying rhythm, to guide optimal anti-arrhythmic therapy.

If the patient had chest pain, hypotension, systolic blood pressure (SBP) less than 90 mmHg, or evidence of cardiac failure, then DC cardioversion would be indicated.

[Q: 1689] OnExamination 2012 - Cardiology

A 63-year-old male is admitted with a 30 minute history of central chest pain associated with nausea and sweating.

His ECG reveals ST elevation in leads II, III and aVF.

Which of the following coronary arteries is most likely to be occluded?

- 1- Circumflex artery
- 2- Left anterior descending artery
- 3- Obtuse marginal artery
- 4- Posterolateral artery
- 5- Right coronary artery

Answer & Comments

Answer: 5- Right coronary artery

The patient has had an inferior myocardial infarction (MI) and this is most likely due to occlusion of the right coronary artery.

Left anterior descending artery (LAD) occlusion results in anterior infarction; circumflex or lateral branch of the LAD results in lateral infarction.

Right coronary artery (RCA) occlusion may also cause posterior infarction.

[Q: 1690] OnExamination 2012 -
Cardiology

A 35-year-old shop worker presents with pain in her calves which develops after 50 yards of walking. The pain settles with rest.

On examination she has yellow discolouration of her palmar creases.

Her fasting lipid profile reveals:

Cholesterol 9.6 mmol/l (<5)

Triglycerides 7.3 mmol/l (<2)

What is the likely diagnosis?

- 1- Chylomicronaemia
- 2- Familial hypercholesterolaemia
- 3- Hypoalphalipoproteinaemia
- 4- Type III hyperlipidaemia
- 5- Type IV hyperlipidaemia

Answer & Comments

Answer: 4- Type III hyperlipidaemia

Remnant hyperlipidaemia (type III hyperlipidaemia) is associated with:

Hypercholesterolaemia, typically 8-12 mmol/l

Hypertriglyceridaemia, typically 5-20 mmol/l

Normal ApoB concentration

Palmar xanthomata - orange discoloration of skin creases

Tuberoeruptive xanthomata - elbows and knees

Early onset of cardiovascular disease

Early onset of peripheral vascular disease.

Remnant hyperlipidaemia is due to abnormal function of the ApoE receptor, which is normally required for clearance of chylomicron remnants and IDL from the circulation.

The receptor defect causes levels of chylomicron remnants and IDL to be higher than normal in the blood stream. The receptor

defect is an autosomal recessive mutation or polymorphism. The genotype of the homozygous condition is apo E-2/E-2 and occurs with a frequency of 1:100.

Hypoalphalipoproteinaemia is a rare, familial condition and is associated with low HDL.

Chylomicronaemia is associated particularly with hypertriglyceridaemia and not with large elevations in cholesterol.

Familial hypercholesterolaemia is due to LDL-receptor deficiency, and is not associated with elevated triglyceride levels.

[Q: 1691] OnExamination 2012 -
Cardiology

Which of the following is not associated with left atrial myxoma?

- 1- A mid-systolic click
- 2- Adrenal hyperplasia
- 3- Left atrial dilatation
- 4- Sudden death
- 5- Systemic emboli

Answer & Comments

Answer: 1- A mid-systolic click

Atrial myxomas in the heart make up 50% of primary cardiac tumours.

They are most common in the left atrium arising from a pedicle on the fossa ovalis. One third present with emboli, a third with systemic inflammation (erythrocyte sedimentation rate [ESR] elevated in 1/3) and a third are asymptomatic when detected.

They can intermittently flop through the mitral valve and cause a mid-diastolic click (tumour plop) when they stop moving.

Elevated left atrial pressures cause dilatation. Syncope can occur due to obstruction. They are more common in women.

Carney's complex is a familial multiple neoplasia and lentiginosis syndrome, associated with:

- Primary adrenal hypercortisolism
- Lentigines and naevi of the skin
- Various tumours including myxoma.

[Q: 1692] OnExamination 2012 - Cardiology

A 76-year-old woman presented with an acute myocardial infarction. The ECG showed ST segment elevation in leads II, III and aVF.

Which coronary artery is most likely to be occluded?

- 1- Circumflex artery
- 2- Diagonal branch of the left anterior descending artery
- 3- Left anterior descending artery
- 4- Left coronary artery
- 5- Right coronary artery

Answer & Comments

Answer: 5- Right coronary artery

This patient has an inferior myocardial infarction which is usually due to occlusion of the right coronary artery.

Less commonly, circumflex occlusion may be responsible.

[Q: 1693] OnExamination 2012 - Cardiology

Which of the following is true regarding the coronary circulation?

- 1- Adenosine is an important mediator of metabolic vasodilatation
- 2- Coronary blood flow is independent of myocardial oxygen consumption due to autoregulation

- 3- Coronary blood flow within a normal range of blood pressure is primarily determined by perfusion pressure
- 4- Increased myocardial O₂ demand is met primarily by increasing O₂ extraction
- 5- The vasodilatory reserve of the epicardium and endocardium is equivalent under normal physiologic conditions

Answer & Comments

Answer: 1- Adenosine is an important mediator of metabolic vasodilatation

Adenosine has a particularly short half life, acts on specific adenosine cell surface receptors (A₁ and A₂) and is inactivated by adenosine deaminase. It results in coronary vasodilatation and depression of sinus node automaticity and AVN conduction.

Coronary blood flow is dependent on myocardial oxygen consumption and is pretty independently maintained throughout the ranges of blood pressure.

Increasing O₂ demands are met by increased blood supply facilitated by vasodilatation brought about by adenosine production.

[Q: 1694] OnExamination 2012 - Cardiology

A 60-year-old man had a myocardial infarction (MI) six weeks ago.

He is taking aspirin 75 mg/day and metoprolol 50 mg 2/day.

During a routine follow up exercise test he has a 20 beat run of non-sustained VT. He achieved stage 4 of the Bruce protocol and 92% of his target heart rate. The non-sustained VT occurred halfway through stage 2. ST segments were normal during the study.

What is the definitive investigation?

- 1- 24 hour Holter monitor
- 2- Coronary angiography

- 3- Echocardiogram
- 4- Electrophysiological study (EPS)
- 5- Thallium exercise scan

Answer & Comments

Answer: 4- Electrophysiological study (EPS)

Post MI ventricular tachycardia (VT) is most commonly due to scar tissue. It may also be related to ischaemia, but no signs of ischaemia were induced.

The definitive investigation would be EPS due to the fact that if this were scar-related VT the site could be localised and even possibly ablated. If not, then an implantable cardio-defibrillator (ICD) implantation may be warranted on MADIT criteria, if left ventricular (LV) dysfunction exists.

Angiography plus thallium may inform us of significant coronary artery disease (CAD) but not offer us a solution to the problem.

An echocardiogram would not be of much use apart from assessing LV function, although in this patient one might assume that LV function is pretty good achieving stage 4 of Bruce protocol, thus an echocardiogram, although required, would not be the definitive test and would be down on the selection list.

There is no need for Holter as the VT has already been recorded.

Reference:

The reference for MADIT is AmJCardiol 1997;79 (suppl 6A):16-7. It was stopped early in 1996 by the steering committee due to extremely positive results in the ICD group. As a consequence it was only published in abstract form. However, MADIT-2 published in the NEJM (Ref: N Engl J Med 2002; 346:877-883, Mar 21, 2002) showed a 5.6% 20 month absolute survival benefit in patients with LV dysfunction (EF<30%), post MI, treated prophylactically with an ICD.

[Q: 1695] OnExamination 2012 - Cardiology

You are working as part of the on-call medical team and a GP calls for some advice about a 62-year-old male patient.

He is a heavy smoker and has a long and extensive history of peripheral vascular disease. He has had two recent admissions under the vascular surgeons, both occasions requiring embolectomy surgery. His GP is unsure which medication to start to reduce his risk of an occlusive vascular event. Unfortunately, the patient is intolerant of aspirin with documented severe allergy. There is no history of stroke or TIA. The patient is in sinus rhythm.

Based on this information and with regard to current NICE guidance, which management option listed is recommended to reduce occlusive vascular events in this patient?

- 1- Clopidogrel
- 2- Dabigatran
- 3- Dipyridamole modified release
- 4- Dipyridamole modified release with clopidogrel
- 5- Warfarin

Answer & Comments

Answer: 1- Clopidogrel

In 2010 NICE released a technology appraisal on the use of clopidogrel and modified release dipyridamole in the prevention of occlusive vascular events. It relates to patients who have had an occlusive vascular event or have established peripheral artery disease (PAD), as with this patient.

Clopidogrel is the first line option for those who have PAD but cannot tolerate aspirin.

Dipyridamole MR is an option for patients who have had a stroke or a TIA but not primary prevention. In combination with aspirin, dipyridamole can be used if the patient has

had a TIA or if they have had a stroke and cannot tolerate clopidogrel. It is an option used alone if they have had a stroke and aspirin/clopidogrel are not tolerated or if they have suffered a TIA and aspirin is not tolerated.

Warfarin is not indicated if they are in sinus rhythm.

Dipyridamole is not indicated in combination with clopidogrel.

Dabigatran is indicated for thromboembolic events post orthopaedic surgery or AF.

Therefore for primary prevention of occlusive vascular events in patients with established PAD but who have not had a stroke/TIA, clopidogrel is the most appropriate choice.

[Q: 1696] OnExamination 2012 - Cardiology

On physical examination a 65-year-old man is found to have pulsus alternans where there is regular alternation of the force of his radial pulse.

Which of the following conditions is the most likely diagnosis?

- 1- Aortic stenosis
- 2- Cardiac tamponade
- 3- Hypertrophic obstructive cardiomyopathy
- 4- Mixed aortic valve disease
- 5- Severe left ventricular failure

Answer & Comments

Answer: 5- Severe left ventricular failure

Pulsus alternans is a physical finding characterised by a regular alternation of the force of the arterial pulse.

It almost invariably indicates the presence of severe left ventricular systolic dysfunction.

NEJM 1996;334(13):834

[Q: 1697] OnExamination 2012 - Cardiology

A 17-year-old male presented with episodes of low back pain.

On clinical examination he is tall and has features of Marfan syndrome. You refer him for echocardiography and he asks why it is needed.

Which of the following is the most common abnormality seen in people with Marfan syndrome?

- 1- Bicuspid aortic valve
- 2- Coarctation of the aorta
- 3- Dilation of the aortic sinuses
- 4- Mitral valve prolapse
- 5- Primum atrial septal defect

Answer & Comments

Answer: 3- Dilation of the aortic sinuses

"The normal aorta has three gentle bulges, the aortic sinuses, just distal to the semilunar attachments of the three leaflets of the aortic valve. The cross sectional diameter of the aorta at the nadir of the leaflet attachment where the aorta and ventricular muscle meet, and at the upper limit of the attachment at the sinutubular junction, are very similar, with the leaflets supported with a spatial relation as if to the sides of a cylinder. The diameter of the more distal circle at the sinutubular junction is, if anything, slightly smaller than the left ventricular outflow. This relation is lost in the Marfan syndrome. The aortic root becomes bulbous and the attachments of the leaflets are splayed out."

Reference:
Heart 2000;84:674-678

[Q: 1698] OnExamination 2012 - Cardiology

A 55-year-old man presents with severe dyspnoea with tachycardia and clinical

examination raises the possibility that pericardial disease may be the cause.

Which of the following clinical features would favour cardiac tamponade rather than constrictive pericarditis?

- 1- Hypotension
- 2- Kussmaul's sign
- 3- Muffled heart sounds
- 4- Pulsus paradoxus
- 5- Raised JVP

Answer & Comments

Answer: 4- Pulsus paradoxus

In cardiac tamponade there is pulsus paradoxus (a greater than 10 mmHg fall in systolic BP on inspiration) but this is less commonly seen in constrictive pericarditis.

Kussmaul's sign (a rise in the jugular venous pressure [JVP] on inspiration) is more likely to be seen in constrictive pericarditis than cardiac tamponade.

[Q: 1699] OnExamination 2012 - Cardiology

A 38-year-old woman with a 10 year history of type 1 diabetes attends for annual review.

She has background diabetic retinopathy, microalbuminuria with a urine albumin:creatinine ratio of 4.8 mg/dl (<3). Currently, she takes basal bolus insulin four times daily and lisinopril.

She is a non-smoker, has a BMI of 30 kg/m² and a blood pressure of 124/70 mm/hg.

Investigations reveal:

- HbA1c 7.3% (3.8-6.4)
- Total cholesterol 5.2 mmol/l (<5.2)
- Triglyceride 1.9 mmol/l (0.45-1.69)
- LDL cholesterol 3.3 mmol/l (<3.36)
- HDL cholesterol 1.3 mmol/l (>1.55)

Which would be the most appropriate treatment for this patient's lipid profile?

- 1- Ezetimibe
- 2- Fenofibrate
- 3- No treatment required
- 4- Omega-3 fatty acids
- 5- Simvastatin

Answer & Comments

Answer: 5- Simvastatin

Type 1 diabetes after a duration of 10 years is associated with a 2% annual coronary heart disease (CHD) event rate, while the risk of cardiovascular events is increased in people with type 1 diabetes by factors such as co-existing microvascular complications, in particular nephropathy.

Furthermore female gender is associated with an approximate twofold increase in relative cardiovascular disease (CVD) risk in type 1 diabetes, while other factors associated with increased CVD risk in type 1 diabetes include:

degree of glycaemia

duration of diabetes

as well as classically recognised factors such as

hypertension

dyslipidaemia.

The most recent CVD treatment guidelines JBS-2 advocate that treatment targets for low density lipoprotein-cholesterol (LDL-C) and total cholesterol (TC) of <2 and <4 mmol/l in all people with diabetes over the age of 40 years, and in those under 40 where there are co-existing risk factors, for example:

Poor glycaemic control (HbA1c >9%)

Co-existing microvascular complications

Presence of another CVD risk factor or

Features of the metabolic syndrome (NCEP ATP III).

Therefore in this case simvastatin would be the most appropriate treatment choice, aiming for a treatment TC <4 mmol/l.

Statins are however not licensed for use in pregnancy, and women of child bearing age need to be counselled regarding pregnancy issues when initiating statin therapy.

Repeat lipid profile is recommended eight weeks following initiation of therapy to enable any therapeutic adjustments to be made.

[Q: 1700] OnExamination 2012 - Cardiology

A 24-year-old female is admitted with palpitations. Her pulse is 160 beats/min, blood pressure 70/50 mmHg and she has a respiratory rate 32/min.

She is awake, alert and oriented but dyspnoeic. Her electrocardiogram shows a regular rhythm with QRS complex width of 0.11s.

What is the most appropriate therapy for this patient?

- 1- Adenosine 6 mg/6 mg/12 mg
- 2- Amiodarone 300 mg
- 3- Atenolol 50 mg
- 4- Direct current cardioversion
- 5- Verapamil 10 mg

Answer & Comments

Answer: 4- Direct current cardioversion

This is highly likely to be a narrow complex tachycardia.

Strictly speaking, as this patient is showing signs of haemodynamic compromise (that is, systolic blood pressure less than 90) she should be immediately DC cardioverted under sedation/anaesthesia.

In practice, most people would try adenosine first whilst organising a cardioversion.

[Q: 1701] OnExamination 2012 - Cardiology

A 16-year-old girl was incidentally found to have delta wave on ECG suggestive of Wolff-Parkinson-White syndrome. There was no tachycardia and she was asymptomatic.

What is the next step in management?

- 1- Beta-blocker therapy
- 2- Electrophysiological study and provocation of arrhythmia
- 3- Radiofrequency catheter ablation of the bypass tract
- 4- Reassurance
- 5- Repeat ECG

Answer & Comments

Answer: 4- Reassurance

The electrocardiogram (ECG) appearances of a delta wave occur in approximately 1.5 per 1000 of the population, but many individuals never experience paroxysmal tachycardias.

The degree of pre-excitation during sinus rhythm is variable: it may be intermittent if the refractory period of the accessory pathway is close to the sinus cycle length, or unapparent if the delta wave is obscured due to rapid AV nodal conduction.

Radiofrequency catheter ablation of bypass tracts is possible in more than 90% of patients and is the treatment of choice in patients with symptomatic arrhythmias.

[Q: 1702] OnExamination 2012 - Cardiology

A 65-year-old woman undergoes temporary pacing due to complete heart block following acute myocardial infarction.

Which coronary artery is most likely to have been occluded?

- 1- Anterior descending

- 2- Circumflex
- 3- Left main coronary
- 4- Obtuse marginal
- 5- Right coronary

Answer & Comments

Answer: 5- Right coronary

Myocardial infarction complicated by bradycardia is most commonly seen in inferior wall myocardial infarction. This area of the heart is supplied by the right coronary artery.

The right coronary artery gives off branches to the sinus node and AV node, therefore disease within this vessel can cause damage to the cardiac conducting system and can thus lead to bradyarrhythmias.

[Q: 1703] OnExamination 2012 - Cardiology

A 65-year-old male attends clinic complaining of breathlessness. He has end stage cardiac failure due to dilated cardiomyopathy. Currently he takes furosemide, lisinopril and carvedilol.

Which one of the following drugs should be added to his current therapy?

- 1- Diltiazem
- 2- Isosorbide mononitrate
- 3- Nicorandil
- 4- Spironolactone
- 5- Vitamin C

Answer & Comments

Answer: 4- Spironolactone

Spironolactone (aldosterone receptor antagonist) is the optimal add on medication for advanced heart failure symptoms.

[Q: 1704] OnExamination 2012 - Cardiology

A 68-year-old woman with atrial fibrillation (AF) is admitted for DC cardioversion.

The procedure resulted in successful restoration of sinus rhythm.

Which one of the following drugs would be most likely to maintain sinus rhythm following this procedure?

- 1- Amiodarone
- 2- Digoxin
- 3- Diltiazem
- 4- Sotalol
- 5- Verapamil

Answer & Comments

Answer: 1- Amiodarone

Amiodarone has been shown to be superior in maintaining sinus rhythm following DC cardioversion of AF, however, it is associated with more toxic side effects than the other agents mentioned.

Neither verapamil, diltiazem nor digoxin would be expected to maintain sinus rhythm to any significant extent.

Sotalol may be considered as a possible therapy but is less effective than amiodarone.

[Q: 1705] OnExamination 2012 - Cardiology

A 40-year-old man attending a routine screening has a blood pressure of 166/100 mmHg. Two weeks later his blood pressure was 150/90 mmHg.

He does not smoke. He drinks 35 units alcohol/week. His body mass index (BMI) is 31.5 kg/m² (20-25).

What is the best management strategy?

- 1- Amlodipine
- 2- Atenolol

- 3- Bendroflumethiazide
- 4- Enalapril
- 5- Lifestyle advice

Answer & Comments

Answer: 5- Lifestyle advice

This 40-year-old man has grade 1 obesity as evidenced by his body mass index.

Grade 1 = 30 - 34.9

Grade 2 = 35 - 39.9

Grade 3 = >40.

Hypertension in this individual is most likely due to obesity-related hypertension or due to pseudo-Cushing's syndrome in view of his high alcohol intake and increased BMI.

Heightened sympathetic nervous system activity

Hyperinsulinaemia, insulin resistance

Hyperleptinaemia

contribute to obesity-related hypertension.

He needs lifestyle advice about reducing his alcohol intake and compatible dietary advice to reduce his weight.

[Q: 1706] OnExamination 2012 - Cardiology

You are helping out the consultant in the afternoon care of the elderly clinic.

Your next patient is a 92-year-old man with a history of aortic stenosis. He has annual transthoracic echocardiograms and his pressure gradient across the valve is stable. He is asymptomatic currently. After the clinic your consultant asks you to discuss each case with her. While discussing this patient, your consultant asks you to explain the pathophysiological mechanisms which occur in aortic stenosis.

From the list, select the pathophysiological response in aortic stenosis.

- 1- Concentric left ventricular hypertrophy
- 2- Eccentric left ventricular hypertrophy
- 3- Increase in myocyte calcium
- 4- Reduced collagen
- 5- Significant fibrosis

Answer & Comments

Answer: 1- Concentric left ventricular hypertrophy

Aortic stenosis (AS) is the most common valve problem in the United Kingdom.

There are a number of compensatory mechanisms to maintain perfusion pressure. However, as time goes on and the valve becomes more narrow, these mechanisms result in the known-later complications of AS.

The LV hypertrophies increase (in the size of myocytes) in a concentric - rather than an eccentric (asymmetric) - manner in response to the increase in afterload.

There is also an increase in interstitial collagen and little fibrosis (hence D and E are incorrect).

There is no change in myocyte calcium.

[Q: 1707] OnExamination 2012 - Cardiology

A 51-year-old traffic warden presents to primary care with incidental asymptomatic hypertension (152 / 84 mmHg). She has no comorbidities. Subsequent serial blood pressure readings are similar.

Which of the following would comprise screening for cardiovascular risk in this patient?

- 1- 24 hour urine collection
- 2- Electrocardiogram
- 3- HbA1C

4- Random lipid level

5- Retinal imaging

Answer & Comments

Answer: 2- Electrocardiogram

Any patient with hypertension should prompt a search for markers of end organ damage and risk factors for cardiovascular disease, from history-taking (headache, epistaxis, visual disturbance), through clinical examination (fundoscopy, site and character of apex beat) to screening investigations. The above incorrect responses all look for micro- and macrovascular complications, yet are not the most rational to use for screening purposes.

A urine dipstick is the first step in identifying proteinuria. Though a positive dip may be a non-specific false positive result, prompting a 24 hour urine collection, a negative dip is reassuring.

Fasting rather than random lipid levels (of total cholesterol and HDL) are of more relevance. Though HbA1C has been suggested by some as a screen for diabetes, fasting glucose remains the currently advocated standard for diagnosing diabetes and impaired glucose tolerance.

Fundoscopy, seeking the arterial changes, cotton wool spots, flame haemorrhages and papilloedema of hypertensive retinopathy, is sufficient to identify ocular complications.

Electrocardiogram screens for hypertensive left ventricular hypertrophy (Sokolow-Lyon criteria: $S1 + V5$ or $V6 > 3.5$ mV).

Renal function tests are also recommended.

Reference:

NICE Clinical Guideline 34: Hypertension. National Institute for Health and Clinical Excellence, London (2006).

[Q: 1708] OnExamination 2012 - Cardiology

A 56-year-old woman presents to the cardiology clinic with increasing attacks of syncope and pre-syncope over the past few months. She is worried that she may have an underlying cardiac defect. She has a 72 hour ECG recording.

Which of the following would be the most significant finding on 72 hour tape?

- 1- 1,000 atrial ectopics recorded over the 72 hours
- 2- 1,000 ventricular ectopics recorded over the 72 hours
- 3- Bradycardia of 40 BPM whilst asleep
- 4- Mobitz type 1 heart block with right bundle branch block (RBBB) whilst feeling light-headed
- 5- Runs of four to six beats of SVT without symptoms

Answer & Comments

Answer: 4- Mobitz type 1 heart block with right bundle branch block (RBBB) whilst feeling light-headed

Second degree heart block with RBBB implies that this patient has a significantly increased risk of complete heart block.

Runs of four to six beats of SVT, and atrial and ventricular ectopics at this rate would be seen as insignificant.

Ultimately, prior to committing to pace maker insertion, repeat tape is the most likely next step, with an electronic patient diary to see if the recorded arrhythmia corresponds to her symptoms.

[Q: 1709] OnExamination 2012 - Cardiology

A 35-year-old lady at 14 weeks' gestation is found to have a blood pressure of 160/100

mmHg. Her father is known to have hypertension.

Electrocardiogram (ECG) demonstrates features of left ventricular hypertrophy (LVH).

What is the most likely diagnosis?

- 1- Eclampsia
- 2- Essential hypertension
- 3- Pre-eclampsia
- 4- Pregnancy-induced hypertension
- 5- Renal hypertension

Answer & Comments

Answer: 2- Essential hypertension

ECG feature of LVH is the key, telling that her hypertension is not of recent onset, ruling out pregnancy-related causes.

Of all types of hypertension, essential hypertension is the most prevalent.

Her family history also supports the diagnosis.

[Q: 1710] OnExamination 2012 - Cardiology

A 60-year-old man presented with a rash over his forearms, shins and face when he visited cardiology clinic in the summer.

Which of the following medications is the most likely to be associated with this photosensitive rash?

- 1- Atenolol
- 2- Bendroflumethiazide
- 3- Clopidogrel
- 4- Digoxin
- 5- Ezetimibe

Answer & Comments

Answer: 2- Bendroflumethiazide

Photosensitivity is a common adverse effect and the cardiology drugs affected include amiodarone and thiazide diuretics.

Angiotensin-converting enzyme (ACE) inhibitors and angiotensin 2 receptor blockers (A2RBs) commonly cause rashes some of which appear to be photosensitive.

[Q: 1711] OnExamination 2012 - Cardiology

Closure of the tricuspid valve is marked by which of the following features of the jugular venous waveform?

- 1- "a" wave
- 2- "c" wave
- 3- "v" wave
- 4- "x" descent
- 5- "y" descent

Answer & Comments

Answer: 2- "c" wave

The "c" wave of the jugular venous waveform is associated with the closure of the tricuspid valve.

[Q: 1712] OnExamination 2012 - Cardiology

A 60-year-old female presents with a four week history of low grade fever, dyspnoea and fatigue.

Two months ago she received a prosthetic valve replacement for mitral regurgitation.

On examination she has a temperature of 37.7°C.

At transoesophageal echocardiography vegetations are seen.

A clinical diagnosis of prosthetic valve endocarditis is made.

Which of the following is the most likely causative organism?

- 1- Actinomycosis
- 2- Candida albicans
- 3- Enterococci
- 4- Staphylococcus epidermidis
- 5- Streptococcus viridans

Answer & Comments

Answer: 4- Staphylococcus epidermidis

Generally there are two identifiable modes of prosthetic valve endocarditis.

The first occurs within the first year after surgery affecting 0.7-3% of cases and is often due to Staphylococci.

Late endocarditis observed after two years post surgery is found in 0.5 - 1% of cases and is typically due to Streptococci - typically alpha haemolytic otherwise known as Strep. viridans.

[Q: 1713] OnExamination 2012 - Cardiology

A 59-year-old male presents with a one hour history of central crushing chest pain. He is known to be diabetic, hypertensive and is a non-smoker.

On examination his pulse rate is 90 beats/min, blood pressure 130/85 mmHg, S1 S2 are audible with no murmurs. There is no evidence of cardiac failure.

An electrocardiogram (ECG) is performed.

Which of the following would be an indication for thrombolysis?

- 1- Atrial fibrillation greater than 150 min-1
- 2- Right bundle branch block
- 3- ST depression of 2 mm in leads II, III, avF
- 4- ST elevation of 2 mm in V4-V6
- 5- Supraventricular tachycardia

Answer & Comments

Answer: 4- ST elevation of 2 mm in V4-V6

This patient is having an acute myocardial infarction (MI); the ECG changes of ST elevation of 2 mm in V4-V6 suggest an anterolateral MI.

Given this history and ECG changes, he should be given thrombolytic treatment, along with aspirin, heparin, beta-blockade, statin therapy and subsequent angiotensin-converting enzyme (ACE) inhibition.

ECG criteria for thrombolysis include:

- ST elevation of more than 1 mm in standard limb leads
- ST elevation more than 2 mm in anterior chest leads
- New left bundle branch block within 24 hours of typical pain.

Evidence beyond 12 hours of pain is equivocal thrombolysis at this time; it tends to be used if there is clinical deterioration or persistent pain.

[Q: 1714] OnExamination 2012 - Cardiology

A 70-year-old woman with established aortic stenosis (AS) attends for annual review.

Which one of the following factors is the most important in deciding the timing of surgery?

- 1- Aortic valve gradient of 50 mmHg
- 2- Left ventricular hypertrophy (LVH)
- 3- The intensity of the murmur
- 4- The patient's symptomatology
- 5- Valvular calcification

Answer & Comments

Answer: 4- The patient's symptomatology

The patient's symptomatology is probably the most important determinant in terms of the decision to operate.

Dyspnoea, chest pain and syncope are all features of aortic stenosis, and when present suggest a poor prognosis if left.

A gradient of 50 mmHg would be regarded as moderate to severe aortic stenosis but if asymptomatic nothing would be done.

LVH is a common feature of AS and does not influence the decision for surgery.

Calcific aortic disease is not of itself important and the gradient should be considered.

[Q: 1715] OnExamination 2012 - Cardiology

Which of the following concerning the use of intravenous bicarbonate in cardiorespiratory arrest is correct?

- 1- Exacerbates intracellular acidosis
- 2- Has a positive inotropic effect on ischaemic myocardium
- 3- Improves oxygen release to the tissues
- 4- Increases cerebral blood flow
- 5- Reduces pre-existent hyperkalaemia

Answer & Comments

Answer: 1- Exacerbates intracellular acidosis

Bicarbonate therapy can increase extracellular pH only if the carbon dioxide (CO₂) produced can be removed by adequate ventilation.

Indeed, if hypercapnia occurs then as CO₂ crosses cell membranes easily, intracellular pH may decrease even further with further deterioration of cellular function.

Bicarbonate has a negative inotropic effect, reducing cerebral blood flow; it shifts the oxygen dissociation curve to the left, inhibiting oxygen release to tissues.

[Q: 1716] OnExamination 2012 - Cardiology

Which of the following antiarrhythmic drugs may be used in the treatment of long QT syndrome?

- 1- Amiodarone
- 2- Atenolol
- 3- Flecainide
- 4- Propafenone
- 5- Sotalol

Answer & Comments

Answer: 2- Atenolol

B-blockers are the mainstay of treatment in long QT syndrome.

The most commonly used drugs are propranolol and nadolol, but metoprolol and atenolol are also used.

Implantable cardioverter-defibrillators are the most effective treatment in high risk cases.

The others drugs may produce a prolongation of the QT interval, exacerbating risk of polymorphic ventricular tachycardia (VT) and torsades de pointes.

[Q: 1717] OnExamination 2012 - Cardiology

A 29-year-old woman with a history of depression is admitted by ambulance after being found unconscious by her boyfriend. Apparently an empty bottle of amitriptyline tablets was found at the scene.

On examination her GCS is 10, her BP is 110/70 mmHg, pulse is 90 and regular. There are no other abnormal findings apart from some scars consistent with deliberate self harm.

Investigations show:

Haemoglobin 13.0 g/dl(11.5-16.0)

White cell count $6.1 \times 10^9/L$ (4-11)

Platelets $152 \times 10^9/L$ (150-400)

Sodium 137 mmol/l (135-146)

Potassium 4.0 mmol/l (3.5-5)

Creatinine 132 micromol/l (79-118)

Bicarbonate 12 mmol/l (22-30)

pH 7.18 (7.35-7.45)

The nurses call you over whilst you are writing up her file as she is having more prolonged runs of VT on the monitor.

What is the next best step?

- 1- Give amiodarone
- 2- Give lidocaine
- 3- Give phenytoin
- 4- Give sodium bicarbonate
- 5- Observe her

Answer & Comments

Answer: 4- Give sodium bicarbonate

This is a rare occasion where sodium bicarbonate is recommended as first line therapy, here for VT / QRS widening in tricyclic poisoning. It provides exogenous sodium to overcome the competitive fast sodium channel blockade produced by tricyclics, and produces an alkalaemia (or reverses acidaemia) that mitigates the fast sodium channel blockade by the tricyclic ingested.

Lidocaine is the second line choice for management of arrhythmias in this situation. It may exacerbate hypotension, so as such is not an appropriate first line choice.

Phenytoin, as well as being an anticonvulsant, may also have a role in suppressing ventricular tachycardia.

Amiodarone or observations alone are not recommended.

[Q: 1718] OnExamination 2012 - Cardiology

A 61-year-old Caucasian patient presents to the gastroenterology clinic following a three month history of malaise with no other specific symptoms.

She had a hysterectomy in her 40s for symptomatic fibroids following completion of her family, and developed pre-eclampsia in both of her pregnancies. She is a current and lifelong smoker, takes no alcohol and previously worked as a secretary.

Present medication consists of Premarin 300 mcg OD, salbutamol PRN, Seretide BD and amlodipine 5 mg OD.

On examination the patient is pale with normal capillary refill time. The heart rate is 72, sinus rhythm. Blood pressure is 145 / 90 mmHg. Chest auscultation revealed neither crackles nor wheeze. Examination is otherwise unremarkable, with normal fundoscopy, urine dip and ECG. Iron deficiency anaemia is seen on full blood count, and outpatient endoscopy is organised.

Other than investigating her present ailment, which additional strategy would be advisable with respect to her hypertension?

- 1- Increase amlodipine to 10 mg
- 2- Prescribe ramipril 10 mg
- 3- Prescribe spironolactone 25 mg
- 4- Repeat blood pressure later
- 5- Screen for pheochromocytoma

Answer & Comments

Answer: 4- Repeat blood pressure later

The incidental abnormality seen in the stressful situation of an outpatient clinic requires observation. Current guidelines advocate rechecking blood pressure should a reading exceeding 140 / 90 mmHg be obtained, primarily at the end of the current consultation.

Those without a prior diagnosis of hypertension merit two further checks a month apart before starting pharmacotherapy, with advice to modify lifestyle factors [dietary, exercise, alcohol and caffeine intake, smoking] in the interim.

Her endoscopy procedure and subsequent consultation to be told of results offer two opportune moments to recheck the blood pressure prior to changing her tablets.

Calcium channel blockers or thiazide diuretics are presently recommended as first-line treatment in those over 55, or all patients of African or Caribbean descent.

Those under 55 with hypertension are advised to start on an ACE inhibitor at first (or ARB blocker should they be intolerant). The starting dose of ramipril is lower than that given in option B (1.25 mg rather than 10 mg), which is uptitrated in the absence of hypotension depending on satisfactory renal function.

Though polypharmacy is in general to be avoided, in a patient with recognised hypertension adding in a second drug is more effective than increasing doses of a first drug. She presently takes a calcium channel blocker, and the next step is addition of an ACE / ARB.

Thiazide diuretics are favoured over potassium-sparing diuretics for blood pressure control.

Screening for pheochromocytoma through assaying a 24 hour urine collection is advocated in patients with more convincing signs of the disease, such as labile blood pressures exceeding 180 /110 mmHg symptoms including headache and palpitations, and signs of end organ involvement including papilloedema, haematuria and left ventricular hypertrophy.

Reference:

NICE 2011 Hypertension guidelines

[Q: 1719] OnExamination 2012 - Cardiology

A 54-year-old man is found to have a prolonged corrected QT interval on his ECG.

Which of the following drugs is the most likely cause?

- 1- Cefaclor
- 2- Digoxin
- 3- Moxonidine
- 4- Sotalol
- 5- Telmisartan

Answer & Comments

Answer: 4- Sotalol

The following are causes of drug-induced long QT:

- Sotalol
- Amiodarone
- Class 1a antiarrhythmic drugs
- Tricyclic antidepressants
- Chloroquine and
- Terfenadine.

[Q: 1720] OnExamination 2012 - Cardiology

A 16-year-old male is brought to emergency admissions with alcohol intoxication.

An initial electrocardiogram (ECG) reveals atrial fibrillation (AF) but a repeat ECG after 12 hours when he has sobered up, shows sinus rhythm. An echocardiogram is normal.

What is the most appropriate management for this patient?

- 1- Aspirin for three months
- 2- Bisoprolol for three months
- 3- Lifestyle advice
- 4- Sotalol for one month
- 5- Warfarin for one month

Answer & Comments

Answer: 3- Lifestyle advice

Excessive alcohol is a recognised cause for atrial fibrillation and is the likely cause here as the rhythm has reverted to sinus after 12 hours. There is also no evidence of structural heart disease as the echocardiogram was normal.

Therefore this patient needs advice regarding moderation of alcohol consumption and needs to be warned of the toxic effects that alcohol can have on the heart and other organs.

There is no indication for short term aspirin.

Atenolol provides rate control, which is not an issue.

Sotalol/amiodarone and flecainide can be used in paroxysmal AF.

Short term warfarin is used for four to six weeks prior to elective cardioversion to protect against embolic complications.

[Q: 1721] OnExamination 2012 - Cardiology

A 67-year-old woman is admitted with blackouts.

Her electrocardiogram shows ventricular escape with complete heart block. As you are standing there she blacks out once more. Her rhythm strip shows P wave asystole.

Which of the following would be the initial immediate treatment here after airway and breathing?

- 1- Adenosine 6 mg
- 2- Adrenaline 1 mg
- 3- Atropine 0.6 mg
- 4- Transcutaneous pacing
- 5- Transvenous pacing

Answer & Comments

Answer: 4- Transcutaneous pacing

Occasionally, atrial electrical activity continues in the absence of ventricular impulses. This is referred to as P-wave asystole and may respond to electrical pacing. This can be achieved by transvenous, transcutaneous or manual techniques. Transvenous pacing takes longer to instigate, and transcutaneous pacing is therefore the initial choice here. Manual pacing is an effective holding measure before more definitive pacing is instituted.

Atropine can also be used, as can adrenaline, for sustained P wave asystole but pacing is the initial treatment of choice. All crash trollies within UK hospitals contain the equipment required to externally pace patients.

Adenosine can induce asystole, and is only indicated in the treatment of supraventricular tachycardias.

[Q: 1722] OnExamination 2012 - Cardiology

A 75-year-old man with atrial fibrillation is successfully cardioverted having had six weeks of anticoagulation.

Which one of the following drugs would be most likely to maintain sinus rhythm following this procedure?

- 1- Amiodarone
- 2- Digoxin
- 3- Nebivolol
- 4- Sotalol
- 5- Verapamil

Answer & Comments

Answer: 1- Amiodarone

Amiodarone is a class 3 anti-arrhythmic and has the best membrane stabilising properties of the above drugs, and is most likely to maintain sinus rhythm (SR).

Sotalol is another class 3 anti-arrhythmic with an ability to maintain SR but is less effective than amiodarone.

[Q: 1723] OnExamination 2012 - Cardiology

A 17-year-old boy whose brother had hypertrophic cardiomyopathy was referred for a cardiological assessment.

His echocardiogram confirmed the condition.

Which one of the following echocardiographic features is the most important risk factor for sudden cardiac death?

- 1- A gradient of 10 mmHg across the left ventricular outflow tract
- 2- An enlarged left atrium
- 3- Significant thickening of the interventricular septum
- 4- Systolic anterior motion of the mitral valve
- 5- The presence of mitral regurgitation

Answer & Comments

Answer: 3- Significant thickening of the interventricular septum

In hypertrophic obstructive cardiomyopathy the cause of death is usually ventricular tachycardia or ventricular fibrillation.

Therefore the thicker the muscle the more abnormal the cardiac architecture and the higher the risk of arrhythmia and sudden death.

[Q: 1724] OnExamination 2012 - Cardiology

Angina due to an imbalance between O₂ supply and demand without atherosclerosis would most likely be seen in which of the following circumstances?

- 1- Aortic regurgitation
- 2- Cardiac tamponade

- 3- Pulmonary regurgitation
- 4- Right heart failure
- 5- Tricuspid regurgitation

Answer & Comments

Answer: 1- Aortic regurgitation

Non-atherosclerotic angina would be associated with conditions such as:

- Thyrotoxicosis
- Aortic regurgitation
- Aortic stenosis
- Hypertrophic cardiomyopathy
- Anaemia

[Q: 1725] OnExamination 2012 - Cardiology

A 72-year-old man presents with an episode of sudden collapse.

He has had two similar episodes recently, each lasting about one minute. Four years ago he suffered an anterior myocardial infarction.

On examination he was orientated and symptom-free with a regular pulse rate of 80 bpm, BP 140/80 mmHg and the apex beat was displaced to the left. There was an apical systolic murmur.

There were no signs of trauma. ECG showed sinus rhythm, Q waves and ST segment elevation anteriorly without reciprocal depression.

What is the diagnosis?

- 1- Acute anterior myocardial infarction
- 2- Cerebrovascular accident
- 3- Epileptic seizure
- 4- Pulmonary embolism
- 5- Ventricular tachycardia

Answer & Comments

Answer: 5- Ventricular tachycardia

The electrocardiogram is suggestive of a left ventricular (LV) aneurysm, which has a tendency for both a malignant arrhythmogenic focus and also for left ventricular thrombus.

The brief episode of loss of consciousness with no residual neurology makes the diagnosis for cerebral embolism unlikely.

The story is more suggestive of a ventricular tachycardia (VT) and would suggest further investigations. Prolonged heart rhythm monitoring and an echo are recommended.

If VT is proven then he should be on amiodarone and the indication for an automated implantable cardioverter/defibrillator strongly considered if the overall LV function is reduced.

[Q: 1726] OnExamination 2012 - Cardiology

Which one of the following statements is true about the Austin Flint murmur?

- 1- It can be distinguished from the murmur of mitral stenosis by absence of presystolic accentuation
- 2- It does not occur in aortic incompetence secondary to an aortitis
- 3- It is an early sign of aortic regurgitation (AR)
- 4- It is associated with a loud first heart sound.
- 5- It is a low frequency mid/late diastolic murmur

Answer & Comments

Answer: 5- It is a low frequency mid/late diastolic murmur

The Austin Flint murmur is a low frequency mid/late diastolic murmur which may show pre-systolic accentuation and is virtually indistinguishable from that of mitral stenosis.

It is due to partial closure of the anterior leaflet of the mitral valve by the regurgitant jet.

There is no correlation between the presence of murmur and severity of AR, or aetiology.

The first heart sound is normal but in severe cases it may be absent.

[Q: 1727] OnExamination 2012 - Cardiology

Which of the following statements concerning the treatment of acute myocardial infarction (MI) is correct?

- 1- A pansystolic murmur developing within the first 24 hours does not require further investigation
- 2- Dipyridamole therapy reduces reinfarction within the first year
- 3- Heparin is beneficial if given with streptokinase
- 4- Prophylactic lidocaine given in the first 48 hours is effective in preventing ventricular fibrillation
- 5- Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality

Answer & Comments

Answer: 5- Treatment with a dihydropyridine calcium antagonist is associated with increased cardiovascular mortality

GISSI II revealed no survival advantage of heparin plus streptokinase in acute MI compared with streptokinase alone.

ISIS II revealed that dihydropyridine calcium antagonists were associated with increased cardiovascular risk after MI.

Dipyridamole does not reduce risk.

A newly discovered pansystolic murmur may signify acquired mitral regurgitation (MR) or ventricular septal defect (VSD).

[Q: 1728] OnExamination 2012 -
Cardiology

You are in a cardiology clinic. A 48-year-old woman has been referred to the cardiology clinic with chest pain. She has been sent for some investigations and has returned to see you for the results.

Investigations have ruled out coronary artery disease but her cholesterol is high. After recording a blood pressure of 150/100 mmHg (for the second time) your CVD risk calculator suggests she should be started on a statin for primary prevention of cardiovascular disease. She has already been given lifestyle advice and is keen to start treatment to reduce her risk further.

You counsel her about starting simvastatin 40 mg once a day. She asks you about her target cholesterol.

What is your response?

- 1- No target cholesterol
- 2- Total cholesterol 5, LDL 3
- 3- Total cholesterol 4, LDL 2
- 4- Total cholesterol 3, LDL 1
- 5- None of the above

Answer & Comments

Answer: 1- No target cholesterol

For primary prevention of cardiovascular disease, there is no target total or low-density lipoprotein (LDL) cholesterol.

Patients with diabetes are considered high risk and are managed in the same way as those with established cardiovascular disease. The target for these patients is: total cholesterol 4; LDL 2.

In these patients there is therefore no need to repeat lipid profile unless patient preference.

[Q: 1729] OnExamination 2012 -
Cardiology

A 65-year-old man presented with chest pain and was found to have ST elevation in leads II, III and aVF.

He was thrombolysed and has been stable on coronary care. On the third day of admission he becomes confused and agitated, and on reviewing the history it becomes apparent that he was a heavy alcohol drinker before admission taking 80 units of alcohol per week.

Which of the following management options would be most helpful in this situation?

- 1- CT brain scan
- 2- Diazepam
- 3- Haloperidol
- 4- Psychiatric referral
- 5- Thiamine

Answer & Comments

Answer: 2- Diazepam

This man is withdrawing from alcohol and this is associated with anxiety and tachycardia which is the last thing that someone who has just had a myocardial infarction (MI) should suffer from. Also there is a risk of seizure.

Benzodiazepines are the first line of treatment for withdrawal.

Thiamine is also indicated in chronic alcoholism but is not as immediately important as diazepam.

A psychiatric referral may be necessary if his symptoms prove difficult to control but usually the psychiatry team would not be keen to intervene in what is really a medical emergency; they often advise on other strategies for sedation however.

This is unlikely to be an intracerebral bleed from thrombolysis on the third day but a computerised tomography (CT) scan may be indicated if there are focal neurological signs.

Haloperidol is best avoided because of the risk of causing hypotension.

[Q: 1730] OnExamination 2012 - Cardiology

A 24-year-old girl with Down's syndrome is found to have a systolic murmur on clinical examination.

What is the most common cardiac defect seen in patients with Down's syndrome that may explain this murmur?

- 1- Endocardial cushion defect
- 2- Mitral regurgitation
- 3- Patent ductus arteriosus
- 4- Secundum atrial septal defect
- 5- Ventricular septal defect

Answer & Comments

Answer: 1- Endocardial cushion defect

Endocardial cushion defects, more commonly known as atrioventricular (AV) canal or septal defects, include a range of defects characterised by involvement of the atrial septum, the ventricular septum, and one or both of the AV valves. (eMedicine)

[Q: 1731] OnExamination 2012 - Cardiology

A 16-year-old boy is admitted after a blackout at the dentist.

His mother describes how he blacked out as the dentist began performing a filling and that he jerked his arms a few times and was then incontinent. He awoke after a minute or so and was oriented but nauseous. There were no similar episodes in the past and he is totally unaware of what happened.

Examination was normal and his ECG was normal.

Which one of the following is the most likely diagnosis?

- 1- Complex partial seizure
- 2- Pseudoseizure
- 3- Stokes-Adams attack
- 4- Tonic-clonic seizure
- 5- Vasovagal syncope

Answer & Comments

Answer: 5- Vasovagal syncope

Vasovagal syncope is common during dental procedures, mainly induced by pain (as the dentist started drilling). The fact that he recovered very quickly supports the diagnosis of syncope. It is common to have jerking of limbs due to brain hypoxia.

Electrocardiogram (ECG) is always normal. Incontinence of urine can occur, but not biting of the tongue.

[Q: 1732] OnExamination 2012 - Cardiology

A 59-year-old man is admitted with chest pain of eight hours duration and has ST elevation in the inferior leads on his admission ECG.

An electrocardiogram from a previous clinic visit shows sinus rhythm two months ago. He has insulin-dependent diabetes mellitus and chronic renal failure.

Investigations reveal:

Fasting plasma glucose 7.4 mmol/l (3.0-6.0)

Sodium 137 mmol/l (137-144)

Potassium 4.4 mmol/l (3.5-4.9)

Urea 10 mmol/l (2.5-7.5)

Creatinine 200 µmol/l (60-110)

Which of the following which represent an absolute contraindication to the use of thrombolysis?

- 1- Allergy to penicillin
- 2- Gastrointestinal bleeding in last three months

- 3- History of haemorrhagic stroke
- 4- Ischaemic stroke 12 months ago
- 5- On warfarin therapy

Answer & Comments

Answer: 3- History of haemorrhagic stroke

Absolute contraindications to thrombolysis include:

Previous haemorrhagic stroke

Ischaemic stroke in last six months

Central nervous system damage or neoplasm

Within three weeks of major surgery, head injury or major trauma

Active internal bleeding (menses excluded) or gastrointestinal bleeding within the past month

Known or suspected aortic dissection

Known bleeding disorder

Proliferative diabetic retinopathy.

Allergy and oral anticoagulants are relative contraindications.

[Q: 1733] OnExamination 2012 - Cardiology

A 65-year-old man presents with a six month history of deteriorating breathlessness.

He is found to have aortic stenosis.

Which one of the following physical signs provides the best clinical marker of the severity of the valvular disease?

- 1- Character of the apex beat
- 2- Character of the carotid pulse
- 3- Character of the second heart sound
- 4- Intensity of the murmur
- 5- Length of the murmur

Answer & Comments

Answer: 5- Length of the murmur

The apex beat in aortic stenosis is not displaced but has a heaving character, the pulse is characteristically of small volume and slow rising, the second heart sound maybe inaudible or paradoxically split.

The murmur tends to become longer as the disease is more severe because of the longer ejection time needed.

The intensity of the murmur is not a good guide to severity as this will become less as the cardiac output is reduced with more severe disease.

[Q: 1734] OnExamination 2012 - Cardiology

A paper describes a new diagnostic test for myocardial infarction (MI).

You want to know what proportion of patients who are classified as not having had a myocardial infarction by the test will actually not have had a myocardial infarction.

Which one of the following measurements would indicate this?

- 1- Accuracy
- 2- Negative predictive value
- 3- Positive predictive value
- 4- Sensitivity
- 5- Specificity

Answer & Comments

Answer: 2- Negative predictive value

The proportion of 'true negatives' not having had a MI correctly identified by this test is called the negative predictive value and refers to the number accurately identified to not have MI by the new test over the number without MI identified by the test + those wrongly identified as not having had an MI.

Specificity is the number without MI accurately identified.

Sensitivity refers to the number correctly identified with MI by the new test.

A positive predictive value refers to the number accurately identified with MI by the test over the number accurately identified with MI + those wrongly identified with MI.

Candidates are often confused about the differences between sensitivity/specificity and positive/negative predictive values. We have had a lot of queries from candidates, asking us why the answer is negative predictive value and not specificity, since the definition of both seems to be similar. There is, however a difference and you may wish to read further into this if you are having similar difficulties. If you consider the example of a condition, for which there is a test - essentially, a knowledge of the sensitivity/specificity is based on the disease state itself, whereas predictive values are based on the test result

[Q: 1735] OnExamination 2012 - Cardiology

A 59-year-old man who was active all his life develops sudden severe anterior chest pain that radiates to his back. Within minutes, he is unconscious.

He has a history of hypertension, but a recent treadmill test had revealed no evidence for cardiac disease.

Which of the following is the most likely diagnosis?

- 1- Acute myocardial infarction (MI)
- 2- Group A streptococcal infection
- 3- Pulmonary embolus
- 4- Right middle cerebral artery embolus
- 5- Tear in the aortic intima

Answer & Comments

Answer: 5- Tear in the aortic intima

The history is typical of aortic dissection.

All the others could cause sudden collapse but not with acute chest pain radiating to the back in the presence of a recent normal exercise test.

Acute MI is possible but not the most likely.

[Q: 1736] OnExamination 2012 - Cardiology

During auscultation of the heart you discover a wide fixed splitting of the second heart sound.

In which of the following conditions does this occur?

- 1- An uncomplicated ASD
- 2- Aortic stenosis
- 3- Constrictive pericarditis
- 4- Fallot's tetralogy
- 5- Right bundle branch block (RBBB)

Answer & Comments

Answer: 1- An uncomplicated ASD

There is a single sound in Fallot's because of an absent P2.

Aortic stenosis leads to reversed splitting (also seen with left bundle branch block [LBBB] and ventricular pacemaker).

In RBBB there is wide splitting of S2 but it is not fixed.

[Q: 1737] OnExamination 2012 - Cardiology

On auscultation of the heart of a 30-year-old female a loud first heart sound is heard.

Which of the following may be responsible for this auscultatory feature?

- 1- A long preceding diastolic interval
- 2- Atrial premature beat
- 3- Increased pulmonary arterial pressure

- 4- Increased systemic arterial pressure
- 5- Rupture of a papillary muscle

Answer & Comments

Answer: 2- Atrial premature beat

A loud first heart sound is due to abrupt closure of the mitral valve against a high left atrial pressure and may occur with shortened diastole, mitral stenosis or left-right shunts.

It can also be heard with atrial premature beats.

Mitral regurgitation occurs with papillary muscle rupture and thereby the first heart sound is soft. A2 and P2 are loud in systemic hypertension and pulmonary hypertension respectively.

[Q: 1738] OnExamination 2012 - Cardiology

A 70-year-old man with dilated cardiomyopathy remains symptomatic in NYHA class 2 due to chronic heart failure.

On examination his pulse is 90 regular, BP 140/90 mmHg, heart sounds normal, chest auscultation did not reveal any abnormalities.

He is currently taking lisinopril 30 mg OD and furosemide 80 mg OD.

What is the best treatment option?

- 1- Amiodarone
- 2- Carvedilol
- 3- Digoxin
- 4- Spironolactone
- 5- Valsartan

Answer & Comments

Answer: 2- Carvedilol

Beta blockers improve mortality and quality of life (QOL) in chronic heart failure (COPERNICUS, MERIT, CIBIS trials).

They should be initiated once patients are stable and can be used in all classes of heart failure though they can cause an acute deterioration in patients who have very severe symptoms. They should be avoided in the acute setting.

Spironolactone improves outcome and symptoms in severe (Class 3-4) chronic heart failure (RALES).

Valsartan does not affect outcome as add-on treatment (VALHEFT).

Digoxin may reduce hospitalisation and improves QOL but has a neutral benefit to mortality (DIG study).

Amiodarone in the absence of arrhythmias does not affect outcome.

[Q: 1739] OnExamination 2012 - Cardiology

A 47-year-old obese lady presents to the Emergency department with a two hour history of central chest pain. This is associated with sweating and breathlessness.

The patient has a history of hypertension and diabetes. Her resting 12 lead ECGs demonstrate significant ST depression in the lateral leads. She has been given 300 mg aspirin by the paramedics. You call the cardiology registrar on-call to discuss the case. There is an on-site cardiac intervention laboratory equipped to manage unstable patients.

In discussion with the cardiology registrar, he asks your opinion on the patient's bleeding risk.

From the list, which of these features is associated with a higher bleeding risk?

- 1- Diabetes
- 2- Low body weight
- 3- Obesity
- 4- Use of proton-pump inhibitors
- 5- Younger age

Answer & Comments

Answer: 2- Low body weight

The early management of unstable angina depends on the use of antiplatelet and anti-thrombotic treatments alongside reperfusion therapy. There are a number of different anti-thrombotic agents and the choice (and dose) varies between centres.

The choice of agent also depends on patient factors, one being the patient's risk of bleeding.

Risk factors for bleeding are:

- Advancing age
- Renal impairment
- Low body weight and
- Known bleeding problems.
- PPIs do not interact in this way.

[Q: 1740] OnExamination 2012 - Cardiology

An elderly lady is admitted to the Emergency department with an episode of syncope. She has a history of high blood pressure on bendroflumethiazide.

On examination her GCS is 15/15. Blood pressure is 135/78 mmHg. Pulse is 60 regular. Cardiovascular and respiratory examination is normal. A focussed neurological examination is also normal. A 12 lead ECG demonstrates sinus rhythm with a normal axis. The corrected QT interval is 540 ms.

You are concerned this patient has had a ventricular arrhythmia leading to syncope. You send bloods urgently for electrolyte estimation.

Which of the following biochemical abnormalities can lead to this problem?

- 1- Hypercalcaemia
- 2- Hyperkalaemia
- 3- Hypoglycaemia
- 4- Hypomagnesaemia

5- Low TSH

Answer & Comments

Answer: 4- Hypomagnesaemia

This question is about acquired long QT syndrome.

Long QT can lead to torsades de pointes and syncope and sudden death. Long QT can be classified as either congenital or acquired.

There are a huge number of acquired causes including drug, biochemical and metabolic causes.

Common biochemical abnormalities include hypocalcaemia, hypokalaemia and hypomagnesaemia.

Hypoglycaemia is not a cause.

Hypothyroidism (and therefore high TSH) can lead to long QT via severe bradycardia.

[Q: 1741] OnExamination 2012 - Cardiology

A 67-year-old man presents to the Emergency department with uncontrolled nausea and vomiting.

He has a long history of COPD for which he takes high dose Seretide and theophylline tablets and has recently been prescribed some antibiotics by his GP for an exacerbation.

On examination his BP is 142/72 mmHg, his pulse is 92 and regular. Auscultation of the chest reveals wheeze and coarse crackles.

Investigations reveal:

Haemoglobin 13.4 g/dl (13.5-17.7)

White cell count $7.1 \times 10^9/L$ (4-11)

Platelets $172 \times 10^9/L$ (150-400)

Sodium 137 mmol/l (135-146)

Potassium 3.0 mmol/l (3.5-5)

Creatinine 115 micromol/l (79-118)

Which of the following antibiotics is he most likely to have been prescribed?

- 1- Amoxicillin
- 2- Azithromycin
- 3- Cefuroxime
- 4- Clarithromycin
- 5- Doxycycline

Answer & Comments

Answer: 4- Clarithromycin

This patient is showing symptoms of theophylline toxicity, and the most likely cause of toxicity is co-prescription of a CYP3A4 inhibitor. Of the options listed, only clarithromycin is a potent 3A4 inhibitor. Azole antibiotics, amiodarone, fluoxetine and cimetidine are other examples.

Azithromycin is a macrolide but is not a significant inhibitor of 3A4. Whilst case reports exist of azithromycin precipitating drug accumulation it is much less likely to do so than clarithromycin or erythromycin.

Amoxicillin, doxycycline and cephalosporins should not lead to theophylline accumulation.

[Q: 1742] OnExamination 2012 - Cardiology

A 69-year-old woman presented with an ulcer over the left ankle, which had developed over the previous nine months. She had a history of right deep vein thrombosis (DVT) five years previously.

On examination she had a superficial slough-based ulcer, 6 cm in diameter, over the medial malleolus with no evidence of cellulitis.

Which one of the following is the most appropriate next investigation?

- 1- Ankle-brachial pressure index
- 2- Bacteriological swab of the ulcer
- 3- Bilateral lower limb arteriogram

- 4- Right leg venogram
- 5- Venous duplex ultrasound scan

Answer & Comments

Answer: 1- Ankle-brachial pressure index

It has been reported that venous ulcerations are the most common type of ulcer affecting the lower extremities. The probable underlying cause of venous congestion, which may promote ulceration, is venous insufficiency.

The treatment of venous ulceration is control of oedema, treating any infection, and compression. However, compressive dressings or devices should not be applied if the arterial circulation is impaired.

It is thus important to identify any arterial disease, and ankle-brachial pressure index is a simple way of doing this. One may then progress to lower limb arteriogram if indicated.

There is no clinical sign of infection, and although a bacterial swab would help to rule out pathogens within the ulcer, arterial insufficiency is the more important issue.

If there is a clinical suspicion of DVT then duplex (or rarely a venogram) is indicated to decide on the indication for warfarin.

[Q: 1743] OnExamination 2012 - Cardiology

A 65-year-old African man with a known history of hypertension presents with ankle oedema after taking an antihypertensive prescribed by his general practitioner. He is now found to have a blood pressure of 180/100 mmHg.

Which of the following would be the preferred drug for this patient?

- 1- Amlodipine
- 2- Atenolol

- 3- Bendroflumethiazide
- 4- Ramipril
- 5- Verapamil

Answer & Comments

Answer: 3- Bendroflumethiazide

The patient has ankle oedema which is usually due to vasodilatation by calcium channel blockers.

The optimal antihypertensive therapy for black Afro-caribbean patients (if a CCB is not suitable, for example because of oedema) will be a thiazide- like diuretic according to current NICE guidance, 2011.

Angiotensin converting enzyme (ACE) inhibitors are preferred for those patients with heart failure or diabetic nephropathy.

β-blockers are preferred for post-myocardial infarction and ischaemic heart disease.

[Q: 1744] OnExamination 2012 - Cardiology

Which of the following is first to rise following myocardial infarction (MI)?

- 1- CK-MB
- 2- Creatine phosphokinase
- 3- Lactate dehydrogenase
- 4- Myoglobin
- 5- Troponin I

Answer & Comments

Answer: 4- Myoglobin

Myoglobin, is a sensitive indicator of muscle injury and is first to rise following MI within two hours but is non-specific.

Troponin and CK-MB both begin to rise approximately three hours after MI. Both are far more specific of myocardial injury.

Lactate dehydrogenase (LDH) begins to rise approximately 12 hours after MI.

[Q: 1745] OnExamination 2012 - Cardiology

A 55-year-old man attends for an insurance medical review.

He has a family history of ischaemic heart disease and has been feeling tired of late.

Investigations reveal:

Total cholesterol 6.8 mmol/L (<5.2)

HDL cholesterol 0.9 mmol/L (>1.55)

Triglycerides 2.2 mmol/L (0.45-1.69)

Free thyroxine 10 pmol/L (10-22)

TSH 22.5 mU/L (0.4-5)

What is the most appropriate treatment for this man's dyslipidaemia?

- 1- 3-Omega fish oils
- 2- Atorvastatin
- 3- Ezetimibe
- 4- Gemfibrozil
- 5- Thyroxine

Answer & Comments

Answer: 5- Thyroxine

This man has subclinical hypothyroidism with a normal thyroxine (T4) but elevated thyroid-stimulating hormone (TSH).

Thyroid hormone is known to play a role in regulating the synthesis, metabolism, and mobilisation of lipids.

It is recognised that the lipid abnormalities tend to resolve following treatment with thyroxine.

[Q: 1746] OnExamination 2012 -
Cardiology

A 72-year-old woman presented with acute severe chest pain with an ECG revealing ST segment elevation in leads II, III and aVF.

She was treated with thrombolysis but two days later became acutely unwell.

Examination revealed a loud systolic murmur at the apex which radiated into the axilla with associated pulmonary oedema.

What is the most likely diagnosis?

- 1- Acute left ventricular failure
- 2- Cardiogenic shock
- 3- Pericarditis
- 4- Ruptured papillary muscle
- 5- Ventricular septal defect

Answer & Comments

Answer: 4- Ruptured papillary muscle

The most likely explanation in this patient with a prior inferior myocardial infarct is mitral valve prolapse due to papillary muscle rupture.

[Q: 1747] OnExamination 2012 -
Cardiology

Which one of the following is a contraindication to thrombolysis?

- 1- Age over 75 years
- 2- Asthma
- 3- Background diabetic retinopathy
- 4- Pregnancy
- 5- The presence of atrial fibrillation

Answer & Comments

Answer: 4- Pregnancy

Those over 75 years benefit from thrombolysis as much or more than younger patients with myocardial infarction (MI).

Proliferative diabetic retinopathy is a relative contraindication.

Important contraindications to thrombolysis include:

- Pregnancy
- Gastrointestinal (GI) bleeding
- Heavy vaginal bleeding
- Recent stroke or surgery
- Uncontrolled severe hypertension
- GI malignancy
- Prolonged cardiopulmonary resuscitation (CPR) (more than half an hour).

[Q: 1748] OnExamination 2012 -
Cardiology

A 70-year-old man is referred by his GP for management of recently diagnosed congestive heart failure. The patient has a history of poorly controlled hypertension.

Over the last three months he has been aware of deteriorating shortness of breath, fatigue, and orthopnoea. Over the last month he had been commenced on digoxin (62.5 µg daily), furosemide (80 mg daily), and amiloride 10 mg.

On examination he has a pulse of 96 bpm regular, a blood pressure of 132/88 mmHg. His JVP was not raised, he had some scattered bibasal crackles on auscultation with a displaced apex beat in the anterior axillary line, sixth intercostal space.

Auscultation of the heart revealed no murmurs and he had peripheral oedema to the mid tibia.

Investigations showed:

Serum Sodium 144 mmol/L(137-144)

Serum Potassium 3.5 mmol/L(3.5-4.9)

Serum Urea 8 mmol/L(2.5-7.5)

Serum Creatinine 135 µmol/L(60-110)

Serum digoxin 0.7 ng/mL(1.0-2.0)

One month previously his urea had been 6 mmol/L and creatinine 110 μ mol/L. An ECG reveals left ventricular hypertrophy and chest x ray shows cardiomegaly and calcified aorta.

What is the most appropriate next step in management?

- 1- Add an ACE inhibitor to the current regimen
- 2- Add atenolol at a dose of 25 mg daily
- 3- Increase digoxin to 0.25 mg daily
- 4- Increase furosemide to 80 mg twice daily
- 5- Maintain on current therapy

Answer & Comments

Answer: 1- Add an ACE inhibitor to the current regimen

This patient would probably be classified as NYHA grade III heart failure (dyspnoeic on mild exertion).

With the persisting symptoms despite 80 mg of furosemide, guidelines would initially suggest the addition of an angiotensin-converting enzyme (ACE) inhibitor.

Although there has been a mild decline in his urea and electrolytes (U+Es) since the introduction of therapy this would not be a contraindication to the use of ACEis. However, it is essential closely to monitor U+Es in this patient following introduction of ACEi.

There is no evidence that increasing the dose of digoxin above 62.5 micrograms in a patient in sinus rhythm would have any added benefit.

B-blockers like carvedilol, metoprolol or bisoprolol in a small dose and gradually uptitrated would be of benefit, however, atenolol has no evidence of clinical benefit in heart failure.

[Q: 1749] OnExamination 2012 - Cardiology

A 17-year-old girl was found collapsed and

drowsy.

Her 12-lead ECG showed a sinus tachycardia of 120 beats per minute with a corrected QT interval of 500 ms (normal <470).

Which of the following drugs is the most likely cause of her presentation?

- 1- Amphetamine
- 2- Diphenhydramine
- 3- Glue sniffing
- 4- Methadone
- 5- Methanol

Answer & Comments

Answer: 2- Diphenhydramine

You are given here the option of choosing between two drugs that can possibly cause prolongation of QT - diphenhydramine and methadone.

However, bearing in mind that she has collapsed and is drowsy with a tachycardia, the most likely option is diphenhydramine as the tachycardia is more typical.

Many drugs can cause a prolonged QT interval.

[Q: 1750] OnExamination 2012 - Cardiology

A 30-year-old pregnant patient is referred to the cardiology clinic with a history of regular fast palpitations. The gestational age is 27 weeks. There is no history of collapse and the patient is usually fit and well.

You examine the patient. Pulse is 105 and regular and the blood pressure is 105/80 mmHg. Venous pressure is not elevated. Heart sounds are normal and a resting 12 lead ECG shows sinus rhythm only.

Regarding the normal pregnancy, which from the list below is an expected physiological change?

- 1- Bradycardia

- 2- Elevated JVP
- 3- Hypertension
- 4- Reduced stroke volume
- 5- Tachycardia

Answer & Comments

Answer: 5- Tachycardia

There are a number of physiological changes which occur during pregnancy.

The heart rate increases by 10-20 bpm, stroke volume and cardiac output increase but venous pressure should remain the same due to a 25% reduction in systemic and pulmonary vascular resistance.

Blood pressure should drop in the first and second trimester and then climb to pre-pregnancy levels by the third trimester.

[Q: 1751] OnExamination 2012 - Cardiology

A 40-year-old man has a hygienist appointment with his dentist for scaling. He is known to have a congenital bicuspid aortic valve.

Which of the following is the most appropriate form of prophylaxis against endocarditis?

- 1- Amoxicillin 1 g IV + gentamicin 120 mg IV pre-procedure
- 2- Amoxicillin 3 g PO pre-procedure
- 3- Gentamicin 120 mg IM pre-procedure
- 4- Metronidazole 1 g PO pre-procedure
- 5- No antibiotics required

Answer & Comments

Answer: 5- No antibiotics required

Although often asymptomatic and affecting 1-2% of the population, bicuspid aortic valve is a risk factor for endocarditis and later development of aortic valve disease.

However, latest NICE guidance (2008) suggests that no prophylaxis is required.

The guideline differs from other advice given by the British Society for Antimicrobial Therapy and the American Heart Association.

It may be prudent still to offer prophylaxis to those at high risk (for example, ventricular septal defect [VSD] or previous infective endocarditis).

[Q: 1752] OnExamination 2012 - Cardiology

A 75-year-old man is admitted to hospital with acute coronary syndrome and is diagnosed with a myocardial infarction (MI).

Four days later he develops a further episode of chest pain with non-specific ST-T wave changes on the ECG.

Which of the following cardiac enzymes would be the most appropriate for deciding if this second episode was a further MI?

- 1- AST
- 2- CK-MB
- 3- LDH
- 4- Troponin I
- 5- Troponin T

Answer & Comments

Answer: 2- CK-MB

Troponin T remains elevated for 10 days following an MI so a second episode of chest pain within that time, suspicious of MI, needs to be evaluated with creatine kinase (CK)-myoglobin (MB) which rises over three days to form a diagnostic profile.

[Q: 1753] OnExamination 2012 - Cardiology

A 68-year-old man has been very ill for months following the onset of chronic liver disease with hepatitis C infection.

He experiences a sudden loss of consciousness and then exhibits hemiplegia on the right. A cerebral angiogram reveals lack of perfusion in the left middle cerebral artery distribution.

What is the most likely cardiac lesion to be associated with this finding?

- 1- Acute rheumatic fever
- 2- Left atrial myxoma
- 3- Libman-Sacks endocarditis
- 4- Non-bacterial thrombotic endocarditis
- 5- Paradoxical thromboembolus

Answer & Comments

Answer: 4- Non-bacterial thrombotic endocarditis

Non-bacterial thrombotic endocarditis (marantic endocarditis) is due to platelet-fibrin thrombi that are prone to embolising.

This form of non-infective endocarditis can be seen in persons who are very debilitated or who have a hypercoagulable state.

The deposition of fibrin on valve leaflets causes sterile vegetations that can embolise.

[Q: 1754] OnExamination 2012 - Cardiology

A 32-year-old female who is 14 weeks pregnant in her third pregnancy is found to have a blood pressure of 152/88 mmHg. There are no other abnormalities of note on examination.

She has a BMI of 33.3 kg/m² and urinalysis is otherwise normal. An ECG reveals left ventricular hypertrophy (LVH).

What is the most likely aetiology of her elevated blood pressure?

- 1- Essential hypertension
- 2- Pre-eclampsia
- 3- Pregnancy-induced hypertension
- 4- Secondary hypertension

- 5- White coat (factitious) hypertension

Answer & Comments

Answer: 1- Essential hypertension

This woman has hypertension which is discovered in her pregnancy but has evidence of LVH on her ECG suggesting that this is long standing.

Often, it takes at least two years of sustained hypertension to develop LVH, and although her pregnancy may have contributed to any deterioration, the LVH suggests that it was pre-existent.

The cause for her hypertension may be secondary but her high BMI is suggestive of it being essential.

[Q: 1755] OnExamination 2012 - Cardiology

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention of ischaemic heart disease in a diabetic population.

1000 patients were randomised to receive the new therapy and 1000 allocated to placebo. The study was completed over a five year period.

In the placebo group there were 150 myocardial infarcts and in the group treated with the new statin there were 100 infarcts.

What is the relative risk reduction of MI afforded by statin therapy?

- 1- 15%
- 2- 25%
- 3- 33%
- 4- 40%
- 5- 50%

Answer & Comments

Answer: 3- 33%

There are 50 fewer MIs in the treated group than the placebo treated group, hence $50/150=33\%$.

The relative risk reduction provides information regarding the efficacy of a therapy and what reduction in risk may be expected when treating subjects rather than just having data relating to the significance of the data.

[Q: 1756] OnExamination 2012 - Cardiology

A publication reports the outcome of a new statin therapy in a placebo controlled primary prevention study of ischaemic heart disease in a diabetic population.

1000 patients were randomised to receive the new therapy and 1000 allocated to placebo.

The study was completed over a five year period.

In the placebo group there were 150 myocardial infarcts (MI) and in the group treated with the new statin there were 100 infarcts.

What is the annual percentage of myocardial infarction in the diabetic population treated with placebo?

- 1- 1%
- 2- 3%
- 3- 5%
- 4- 7%
- 5- 10%

Answer & Comments

Answer: 2- 3%

This study shows that there are 150 MIs in 1000 diabetic patients treated over a five year period in the placebo group.

Hence the rate of infarction in this group is $150/1000=15\%$, divided by five years to give the annual MI rate of 3%.

[Q: 1757] OnExamination 2012 - Cardiology

Which of the following is the most likely mechanism by which aspirin exerts its beneficial effects in patients with coronary artery disease?

- 1- Anti-inflammatory action
- 2- Cyclo-oxygenase (COX) inhibition
- 3- Glycoprotein IIB/IIIA receptor inhibition
- 4- Inhibition of binding of adenosine diphosphate (ADP) to its platelet receptor
- 5- Structural changes in platelets

Answer & Comments

Answer: 2- Cyclo-oxygenase (COX) inhibition

It inhibits platelet aggregation through inhibition on both COX I and II.

Clopidogrel inhibits ADP binding to platelet receptors.

[Q: 1758] OnExamination 2012 - Cardiology

A 70-year-old man is admitted with an acute Q wave inferior myocardial infarction (MI).

On day five, he suddenly develops pulmonary oedema and a loud systolic murmur.

Which of the following would be the most useful in establishing a diagnosis?

- 1- Chest x ray
- 2- Coronary arteriography
- 3- ECG
- 4- Right heart catheterisation and oximetry
- 5- Serum cardiac enzymes

Answer & Comments

Answer: 4- Right heart catheterisation and oximetry

This patient has developed acute left ventricular failure (LVF) five days after an inferior MI.

Things to think about include mitral valve (MV) prolapse, ventricular septal defect (VSD) or acute pericardial effusion/haemorrhage.

Right heart studies would provide information on left atrium (LA) pressures and suggestive information on the most likely diagnosis: MV prolapse.

[Q: 1759] OnExamination 2012 - Cardiology

A 44-year-old man has had no major medical problems throughout his life, except for arthritis pain involving all extremities for the past couple of years.

He has had worsening orthopnoea and ankle oedema in the past six months. He is afebrile. There is no chest pain. A chest x ray shows cardiomegaly with both enlarged left and right heart borders, along with pulmonary oedema.

Laboratory test findings include:

Sodium 139 mmol/l (137-144)

Potassium 4.3 mmol/l (3.5-4.9)

Urea 7 mmol/l (2.5-7.5)

Creatinine 95 µmol/l (60-110)

Glucose 8.6 mmol/l (3.0-6.0)

Which of the following additional laboratory test findings is he most likely to have?

- 1- Anti-centromere antibody titre of 1:320
- 2- Erythrocyte sedimentation rate of 79 mm/hr
- 3- Haemoglobin of 10.7 g/dl with MCV of 72 fl
- 4- Serum ferritin of 3400 pmol/l
- 5- Spherocytes in his peripheral blood smear

Answer & Comments

Answer: 4- Serum ferritin of 3400 pmol/l

He has findings of a cardiomyopathy with right and left heart failure. Hereditary haemochromatosis (HHC) is suspected with a serum ferritin greater than 1000 and confirmed by genetic testing.

Hereditary haemochromatosis is characterised by diabetes, congestive cardiac failure (CCF), pseudogout and slate-grey skin.

"HHC is an autosomal recessive condition and in 90% of cases in the United Kingdom (UK) the condition is owing to homozygosity for the C282Y mutation in the HFE gene. A second mutation in the HFE gene, H63D, can cause the disease when in the presence of a single C282Y mutation (the so-called 'compound heterozygote' state). These mutations are common in people of Northern European origin with a carrier frequency of the C282Y mutation of one in 10-17, in the UK, suggesting a prevalence of people homozygous for the C282Y mutation of between one in 100 and one in 280.

"If HHC becomes symptomatic by mid-life, a general practitioner (GP) with a list size of 2,000 patients should have approximately four cases. In our experience most GPs claim to have never seen a case. Herein lies the conundrum: is HHC far more common than is currently recorded in clinical records and death registers because it is not being diagnosed, or does significant disease not develop in a large proportion of C282Y homozygotes and compound heterozygotes?"

[Q: 1760] OnExamination 2012 - Cardiology

A 21-year-old man with hypertrophic cardiomyopathy presents in clinic with dizzy spells but has not had any syncopal episodes.

Which of the following, if present, would indicate an increased risk of sudden cardiac death?

- 1- Asymmetric septal hypertrophy with maximum wall thickness of 2.1 cm

- 2- Blood pressure drop of 20 mmHg during peak exercise tolerance testing
- 3- Left ventricular outflow tract gradient of 80 mmHg
- 4- Systolic anterior movement of the mitral valve on echocardiography
- 5- Worsening exertional angina

Answer & Comments

Answer: 2- Blood pressure drop of 20 mmHg during peak exercise tolerance testing

Patients with hypertrophic cardiomyopathy (HCM) are at increased risk of sudden cardiac death due to ventricular fibrillation/tachycardia (VF/VT).

The five poor prognostic markers which are predictive of sudden cardiac death are:

Syncope

Family history of HCM and sudden cardiac death

Maximum left ventricular wall thickness greater than 3 cm

Blood pressure drop during peak exercise on stress testing

Documented runs of non-sustained VT on 24 hour tape.

Left ventricular outflow tract (LVOT) obstruction causes symptoms and can lead to deterioration of LV function but does not predict sudden cardiac death.

Asymmetric septal hypertrophy is a feature of HCM; in order to assess the risk for sudden cardiac death a detailed echocardiogram with measurements of the maximum left ventricular wall thickness is required.

Systolic anterior movement of the mitral valve is often seen on echocardiogram and is thought to be the mechanism behind the left ventricular outflow tract obstruction.

[Q: 1761] OnExamination 2012 - Cardiology

Your next patient in the care of the elderly clinic is a 79-year-old lady who you initially saw two months ago with a history of palpitations. She has a history of stable coronary artery disease (CAD) and controlled hypertension on bendroflumethiazide. She remains active and lives alone independently.

When you saw her last you sent her for an echo. This demonstrates good LV function, mild concentric LVH and a dilated LA (AP diameter 5.7 cm). A 24 hour ECG has shown AF throughout, maximal rate 135. On questioning during this consultation she has noted a few episodes of palpitations lasting a few hours. Today her ECG confirms AF.

What is the most appropriate initial management of her arrhythmia?

- 1- Arrange DC cardioversion
- 2- Start amiodarone
- 3- Start bisoprolol
- 4- Start digoxin
- 5- Start sotalol

Answer & Comments

Answer: 3- Start bisoprolol

This question tests knowledge of the recommended initial strategy for patients with AF (that is, rhythm or rate control). The decision to start either strategy is based on symptoms and other clinical features.

This patient should be offered rate control in the first instance because she is older (>65), has a history of CAD and has a large left atrium (>5.5cm) which makes cardioversion less likely to be successful.

Initial treatment for a rate control strategy is either a standard β -blocker (that is, bisoprolol) or calcium channel blocker. Digoxin should only be used first line for patients who are predominantly sedentary or hypotensive.

Therefore the correct choice is start bisoprolol. The patient should also be considered for anti-coagulation based on her CHADS₂ score.

Reference:

NICE guideline 36 (2006): Atrial fibrillation

[Q: 1762] OnExamination 2012 - Cardiology

An 83-year-old man is referred to the cardiology clinic with a history of palpitations.

He presented to his GP after two days of fast, irregular palpitations. The GP noted an irregular pulse and a 12 lead ECG confirmed atrial fibrillation. He has been referred to you for assessment. In clinic today he is in sinus rhythm. His usual state of health is good; he lives independently with this wife and suffers from controlled hypertension.

He has read in the newspaper about stroke risk associated with AF and asks if he needs any medication to reduce his risk.

From the list, select the most appropriate response.

- 1- Aspirin 75 mg once a day
- 2- Aspirin 300 mg once a day
- 3- Clopidogrel 75 mg once a day
- 4- No anticoagulation necessary
- 5- Warfarin, dose adjusted to INR

Answer & Comments

Answer: 5- Warfarin, dose adjusted to INR

This patient is diagnosed with paroxysmal AF, and is in sinus rhythm when you review him.

2006 NICE guidelines (CG 36) state the decision to offer antithrombotic therapy is dependent on the patient's risk rather than if they are in paroxysmal, persistent or permanent AF.

As this patient is above 75 and is hypertensive the guidelines suggest warfarin, hence warfarin, dose adjusted to INR, is correct.

Useful clinic tools to decide on appropriate therapy are the CHADS₂ and CHADS₂-vasc scores.

Clopidogrel and aspirin 300 mg OD are not recommended for this indication.

[Q: 1763] OnExamination 2012 - Cardiology

A 55-year-old non-smoker presents to the acute medical take with a one month history of chest pain on exertion. There has been no rest pain or deterioration in symptoms.

You perform a full assessment in the Emergency department including a resting 12 lead ECG, which is normal. He is normotensive. His total cholesterol is 5.2. He is not diabetic.

Based on your assessment you feel that he does not need admission. On the post-take ward round your consultant (who is a cardiologist) agrees but asks you to recommend the next investigation based on current NICE guidelines.

From the list below, select the most appropriate response to your consultant's question.

- 1- Cardiac CT with calcium scoring
- 2- Cardiac MR
- 3- Dobutamine stress echocardiography
- 4- Exercise tolerance test
- 5- Invasive coronary angiogram

Answer & Comments

Answer: 5- Invasive coronary angiogram

Coronary angiogram is recommended for investigation of patients presenting with stable angina and a 61-90% chance of ischaemic heart disease (IHD).

NICE published a clinical guideline on the assessment and diagnosis of chest pain of recent onset in March 2010 (CG95). This recommends triage of these patients into at risk groups (10-29%, 30-60%, 61-90%, >90% likelihood of IHD) based on history of symptoms and risk factors (DM, age, smoking, cholesterol).

They provide complex tables which allow you to decide on the initial diagnostic test depending on the patient's profile. Above 90% should be treated as angina without tests.

This patient's risk is 80% and should be referred for invasive coronary angiography.

Despite its very wide use, exercise tolerance testing is no longer recommended for the assessment of patients for angina without known coronary artery disease.

Therefore the correct answer is invasive coronary angiography.

[Q: 1764] OnExamination 2012 - Cardiology

A 35-year-old healthy woman has a faint systolic murmur on physical examination. An echocardiogram is performed, and she is found to have a bicuspid aortic valve.

In explaining the meaning of this finding to her, which is the most appropriate statement?

- 1- An aortic valve replacement is eventually likely to be required
- 2- Other family members are likely to have the same condition
- 3- She should be treated with a cholesterol-lowering agent
- 4- The problem has resulted from past injection drug usage
- 5- This is one manifestation of an underlying autoimmune disease process

Answer & Comments

Answer: 1- An aortic valve replacement is eventually likely to be required

Bicuspid aortic valve (BAV) is perhaps the most common form of congenital heart disease in adults (1-2% of population).

Bicuspid valves have a propensity to wear out and calcify with ageing. Bicuspid aortic valve tends to be sporadic although there is a reported familial incidence of approximately 9%.

From a review of several sources in the literature, the Aeromedical Consultation Service (ACS) at Brooks AFB calculated a 1.2% per year incidence of aortic valve surgery in individuals with BAV, although the vast majority occur in the fifth and sixth decades of life.

[Q: 1765] OnExamination 2012 - Cardiology

A 23-year-old man attended his local NHS walk-in centre with a history of chest pains.

The doctor arranged a 12 lead ECG which he is surprised to find suggests left ventricular hypertrophy. The doctor decides to refer the patient to the local acute medical department. The patient is admitted and the next day has a transthoracic echocardiogram. This demonstrates asymmetric septal hypertrophy with a small LV cavity. Systolic function appears normal.

The cardiologist explains the diagnosis of probable hypertrophic cardiomyopathy. On the ward round the next day the patient is worried about the associated risk of death.

Which of the features listed is a recognised risk factor for sudden cardiac death?

- 1- Atrial fibrillation
- 2- Drop in systolic blood pressure of 25 mmHg on exercise
- 3- Mitral regurgitation

- 4- Older age at diagnosis
- 5- Systolic anterior motion of the mitral valve leaflets

Answer & Comments

Answer: 2- Drop in systolic blood pressure of 25 mmHg on exercise

Hypertrophic cardiomyopathy (HCM) is often asymptomatic and is noticed following routine ECGs or echocardiograms for other reasons.

HCM is a complex disease and there is a wide variability in severity and risk of serious complications (mainly ventricular arrhythmias).

Unfortunately risk of sudden cardiac death (SCD) is difficult to predict but there are recognised risk factors. Younger age at diagnosis and non-sustained VT are markers of risk. Abnormal blood pressure response to exercise is a marker for risk of SCD.

[Q: 1766] OnExamination 2012 - Cardiology

A 22-year-old man undergoes ECHO screening for HOCM.

His father died suddenly at the age of 43, and was found on post mortem to have underlying HOCM. On further questioning it transpires that there is a family history of sudden cardiovascular death.

On examination his BP is measured at 142/84 mmHg. His pulse is 78 and regular. There is a double apex beat and a mid-systolic murmur. ECHO reveals a septal wall thickness of 3.3 cm.

Which of the following factors is most closely linked to his 20 year risk of sudden cardiac death?

- 1- BP of 142/84 mmHg
- 2- Double apex beat
- 3- History of sudden cardiac death in the family

- 4- Intensity of his systolic murmur
- 5- Septal wall thickness of 3.3 cm

Answer & Comments

Answer: 5- Septal wall thickness of 3.3 cm

Prediction of sudden cardiac death risk in hypertrophic obstructive cardiomyopathy (HOCM) is notoriously difficult, but septal wall thickness greater than 3 cm is associated with a significantly increased risk. A study in the NEJM put the 20 year risk of sudden cardiac death at almost 40% for this population, even in the absence of symptoms such as angina or syncope.

It is most likely that septal hypertrophy increases the risk of ventricular arrhythmias.

Other factors known to mark out increased risk of sudden death include documented collapse, or ventricular arrhythmias documented on Holter monitoring, both of which would prompt consideration of an implantable cardioverter defibrillator.

[Q: 1767] OnExamination 2012 - Cardiology

A 72-year-old man presented following three episodes of transient loss of consciousness not associated with chest pain. There was a previous history of an anterior myocardial infarction.

On examination his blood pressure was 140/80 mmHg and the apex beat was diffuse in character and displaced to the left. There were no neurological signs.

The ECG showed sinus rhythm with occasional ventricular extrasystoles, deep anterior Q waves and ST segment elevation in leads V2 - V6, without reciprocal depression.

Which one of the following would be the most appropriate initial course of action?

- 1- Administer tissue plasminogen activator
- 2- Arrange an electroencephalogram

- 3- Arrange immediate computerised tomography (CT) brain scan
- 4- Observe in the coronary care unit
- 5- Proceed to coronary arteriography

Answer & Comments

Answer: 4- Observe in the coronary care unit

The history suggests that this man has persistent ST elevation in the anterior leads, with a previous history of anterior myocardial infarction due to left ventricular (LV) aneurysm. The blackouts are cardiac syncope due to rhythm disturbance. An ECHO would quickly support the diagnosis but, because of the risk of sudden death, observation on CCU is required.

The loss of consciousness is likely to be due to recurrent arrhythmic episodes or vertebrobasilar transient ischaemic attacks (TIAs), as a result of embolisation of an LV thrombus.

The most important investigation for this patient whom you suspect has arrhythmic episodes would be telemetry/24 hour monitoring, and hence observation on the coronary care unit (CCU) is appropriate.

[Q: 1768] OnExamination 2012 - Cardiology

A study reveals an immediate rise in blood pressure following infusion of a hormone in normal volunteers.

Which of the following is the most likely hormone used in this study?

- 1- Angiotensin I
- 2- Angiotensin II
- 3- Atrial natriuretic peptide (ANP)
- 4- Brain natriuretic peptide (BNP)
- 5- Prolactin

Answer & Comments

Answer: 2- Angiotensin II

Angiotensin II when infused intravenously produces an immediate rise in blood pressure being a potent vasoconstrictor.

Both BNP and ANP result in natriuresis and lowering of blood pressure.

Prolactin has no specific effect.

[Q: 1769] OnExamination 2012 - Cardiology

A 65-year-old male with left ventricular systolic dysfunction was dyspnoeic on climbing stairs but not at rest. The patient was commenced on ramipril and furosemide.

Which one of the following drugs would improve the patient's prognosis further?

- 1- Amiodarone
- 2- Digoxin
- 3- Diltiazem
- 4- Isosorbide mononitrate
- 5- Metoprolol

Answer & Comments

Answer: 5- Metoprolol

This patient has NYHA grade II heart failure and is already receiving angiotensin converting enzyme (ACE) inhibitors and diuretics.

Studies such as CIBIS, MERIT HF and COPERNICUS clearly demonstrate the advantage of β -blockers even with severe heart failure.

[Q: 1770] OnExamination 2012 - Cardiology

A 74-year-old man presented with acute pain, pallor and absent pulses in his right leg.

Investigations revealed an embolus in his femoral artery.

What is the most likely source of this embolus?

- 1- Marantic endocarditis
- 2- Paradoxical emboli
- 3- Rheumatic endocardial vegetations
- 4- Right ventricular thrombi
- 5- Thrombi from an atheromatous aorta

Answer & Comments

Answer: 5- Thrombi from an atheromatous aorta

Ulceration of an atheromatous plaque of the abdominal aorta is the most common source of emboli in this situation.

Right ventricular thrombi would embolise to the lung.

The others are possible but less likely causes.

[Q: 1771] OnExamination 2012 - Cardiology

A 62-year-old man has experienced substernal chest pain upon exertion with increasing frequency over the past one year.

An electrocardiogram shows T wave inversion in the anterolateral leads at rest. He has a total serum cholesterol of 7.0 mmol/l (<5.2).

On angiography, he has an 85% narrowing of the left anterior descending (LAD) artery.

Which of the following events is most likely to occur in this patient?

- 1- A systemic artery embolus from a left atrial mural thrombus
- 2- A systemic artery embolus from a left ventricular mural thrombus
- 3- A systemic artery embolus from thrombosis in a peripheral vein
- 4- Pulmonary embolism from a left ventricular mural thrombus

- 5- Pulmonary embolism from thrombosis in a peripheral vein

Answer & Comments

Answer: 2- A systemic artery embolus from a left ventricular mural thrombus

The suggestion here is that this man has coronary artery disease with an impending myocardial infarction.

Infarction of the LAD would cause necrosis of the left ventricle.

Thrombus may form on an area of dyskinetic ventricle. Therefore he is most at risk of embolus of thrombus from the left ventricle (LV).

[Q: 1772] OnExamination 2012 - Cardiology

Which of the following statements is true of coronary artery anatomy?

- 1- Right bundle branch block in acute anterior myocardial infarction suggests obstruction prior to the first septal branch of the left anterior descending coronary artery
- 2- The AV node is supplied by the left anterior descending coronary artery
- 3- The left main stem is about 4 cm long
- 4- The posterior descending artery is usually a branch of the circumflex artery
- 5- The sinus node is supplied by a branch of the right coronary in over 90% of subjects

Answer & Comments

Answer: 1- Right bundle branch block in acute anterior myocardial infarction suggests obstruction prior to the first septal branch of the left anterior descending coronary artery

It is sometimes said that options longer than two lines are usually false - but not in this case. The posterior descending artery is most

often (85%) a branch of the right coronary artery.

The sinus node artery is a branch of the right coronary artery in 60% of cases.

The AV node is supplied from the right coronary artery.

The left main stem is much shorter than 4 cm.

[Q: 1773] OnExamination 2012 - Cardiology

A 43-year-old man is on the coronary care unit after suffering a large anterior myocardial infarction. Fortunately he recovered well following timely reperfusion treatment. After the ward round his wife asks for some advice on how he can reduce the risk of this happening again.

From the list of activities below, which is recommend by NICE for secondary prevention of myocardial infarction?

- 1- 20-30 minutes of physical activity a day
- 2- Abstain from alcohol
- 3- Beta-carotene supplements
- 4- Cut down cigarette use
- 5- Vitamin E supplements

Answer & Comments

Answer: 1- 20-30 minutes of physical activity a day

Following a myocardial infarction, NICE recommends a number of lifestyle modifications as prevention. These include increasing physical activity to 20-30 minutes per day, which seems daunting to patients who may not have exercised as such since school.

It advises this is increased slowly and cardiac rehabilitation classes can help promote and encourage this.

Abstinence from alcohol is not recommended per se, but should be used in moderation.

Smokers should be encouraged to stop, and cutting down does not work.

Vitamin E and beta-carotene supplements are specifically mentioned and are not to be recommended.

[Q: 1774] OnExamination 2012 - Cardiology

A 60-year-old man presents with features of left ventricular failure.

He is comfortable at rest but ordinary physical activity results in fatigue and shortness of breath.

Which of the following New York Heart Association's classifications best match the severity of this man's disease?

- 1- Normal
- 2- NYHA Class I
- 3- NYHA Class II
- 4- NYHA Class III
- 5- NYHA Class IV

Answer & Comments

Answer: 3- NYHA Class II

In 1928 the New York Heart Association published a classification of patients with cardiac disease based on clinical severity and prognosis.

This classification has been updated in seven subsequent editions of Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Great Vessels (Little, Brown & Co). The ninth edition, revised by the Criteria Committee of the American Heart Association, New York City Affiliate, was released March 4, 1994.

"Class II. Patients with cardiac disease resulting in slight limitation of physical activity. They are comfortable at rest.

Ordinary physical activity results in fatigue, palpitation, dyspnea or anginal pain."

[Q: 1775] OnExamination 2012 - Cardiology

A 16-year-old profoundly deaf boy on holiday in the United Kingdom from Denmark presents with recurrent episodes of syncope and is found to have a long QT interval on his ECG.

His faxed medical records indicate that he has Jervell and Lange-Nielsen syndrome.

Which of the following genes is affected in this condition?

- 1- CACNA1c gene
- 2- Caveolin 3 related gene
- 3- Human ether-à-go-go related gene (hERG)
- 4- KCNQ1 gene
- 5- SCN5A gene

Answer & Comments

Answer: 4- KCNQ1 gene

Mutations in the KCNE1 and KCNQ1 genes cause Jervell and Lange-Nielsen syndrome.

The KCNE1 and KCNQ1 genes provide instructions for making proteins that work together to form a channel across cell membranes. These channels transport positively charged potassium atoms (ions) out of cells. The movement of potassium ions through these channels is critical for maintaining the normal functions of inner ear structures and cardiac muscle.

All the other genes mentioned are associated with long QT syndromes.

The human ether-à-go-go related gene (hERG) is the gene affected by drugs that lengthen QT interval inadvertently; erythromycin, terfenadine, and ketoconazole.

[Q: 1776] OnExamination 2012 - Cardiology

An elderly man with a history of asthma, congestive heart failure, and peptic ulcer disease is admitted with bronchospasm and rapid atrial fibrillation. He is given nebulised salbutamol frequently, a loading dose of oral digoxin, and oral prednisolone. His regular medications are continued. 24 hours after admission his plasma potassium is noted to be 2.8 mmol/l.

Which of his medications is most likely to have caused this abnormality?

- 1- ACE inhibitor
- 2- Digoxin
- 3- Ranitidine
- 4- Salbutamol
- 5- Spironolactone

Answer & Comments

Answer: 4- Salbutamol

High doses of parenteral and nebulised salbutamol are associated with hypokalaemia. This effect may have been potentiated by concomitant treatment with prednisolone.

Spironolactone and ACE inhibitors commonly cause hyperkalaemia (their use in combination is potentially dangerous and requires regular monitoring of serum electrolytes).

Electrolyte disturbance with ranitidine is unlikely.

Digoxin does not cause hypokalaemia (unless due to vomiting associated with digoxin toxicity). Hypokalaemia increases cardiac sensitivity to digoxin and predisposes the patient to digoxin toxicity; correction of hypokalaemia is recommended to avoid arrhythmias.

[Q: 1777] OnExamination 2012 -
Cardiology

Which of the following cardiac drugs shorten the QT interval?

- 1- Amiodarone
- 2- Digoxin
- 3- Moxonidine
- 4- Sodium nitroprusside
- 5- Sotalol

Answer & Comments

Answer: 2- Digoxin

Hypercalcaemia, hypermagnesaemia, digoxin, or thyrotoxicosis cause QT shortening.

[Q: 1778] OnExamination 2012 -
Cardiology

A 68-year-old lady presents to her GP for an annual review of her heart failure treatment.

She has a blood pressure of 165/90 mmHg. She is currently taking furosemide and aspirin and she experiences dyspnoea on walking up hills.

Which of the following is the most appropriate medication to add?

- 1- Bendroflumethiazide
- 2- Enalapril
- 3- Isosorbide mononitrate
- 4- Spironolactone
- 5- Titrate dose of furosemide

Answer & Comments

Answer: 2- Enalapril

Angiotensin-converting enzyme (ACE) inhibitors remain one of the cornerstones of the treatment of heart failure (SOLVD and CONSENSUS trials).

There is clear evidence that higher doses exert greater benefit.

They are usually very well tolerated, especially in milder cases.

Reference:

Heart 2000;84(Suppl 1):i8-i10

[Q: 1779] OnExamination 2012 -
Cardiology

A 66-year-old man with insulin-dependent diabetes given ibuprofen for a knee injury is admitted with palpitations.

His electrocardiogram (ECG) shows a rate of 105 beats per minute, with absent P waves and tall T waves.

His urea and electrolytes show:

Sodium 132 mmol/l (137-144)

Potassium 6.4 mmol/l (3.5-4.9)

Urea 11 mmol/l (2.5-7.5)

Creatinine 180 µmol/l (60-110)

In this scenario, which of the following is the most appropriate immediate management?

- 1- Calcium chloride 10 mmol IV
- 2- Calcium resonium orally
- 3- Dextrose 50 mls 50% with 10 units insulin
- 4- Dialysis
- 5- Furosemide 1 mg/kg IV

Answer & Comments

Answer: 1- Calcium chloride 10 mmol IV

The ECG suggests cardiotoxicity related to hyperkalaemia and the history of palpitations is suggestive of arrhythmias.

Therefore cardio protection with calcium chloride or gluconate should be first priority and lowering potassium levels immediately thereafter.

[Q: 1780] OnExamination 2012 -
Cardiology

A 43-year-old gentleman develops chest pain

seven minutes after fiberoptic bronchoscopy.

The procedure had been performed without sedation following an intratracheal injection of 5 ml 2.5% cocaine solution and xylocaine spray to the pharynx for topical anaesthesia.

ECG showed an evolving anterior myocardial infarction.

Which of the following would you prefer for his management?

- 1- Beta-blockers
- 2- Nitrates
- 3- Percutaneous transluminal coronary angioplasty
- 4- Thrombolysis with rt-PA
- 5- Thrombolysis with streptokinase

Answer & Comments

Answer: 2- Nitrates

The underlying mechanism here is vasoconstriction, not thrombosis.

Cocaine is cardiotoxic and its use has been linked to:

- Coronary artery spasm
- Angina
- Myocardial infarction
- Arrhythmias
- Sudden cardiac death

Myocardial contraction bands, which might act as a substrate for arrhythmias.

It is important to avoid β -blockers in treating cocaine-induced chest pains or acute myocardial infarctions, as this may result in unopposed α adrenergic action with worsening coronary spasm.

Calcium channel antagonists or nitrates should be administered as early as possible.

[Q: 1781] OnExamination 2012 - Cardiology

A 50-year-old male is admitted with a three hour history of central chest pain sweating and nausea.

He has no relevant past medical history although his father died of an MI at the age of 48 and he is a smoker of five cigarettes per day. He currently takes no medication. He is seen in the morning on the consultant ward round 12 hours after admission and his pain has now settled.

Examination reveals no specific abnormality and his ECG is normal.

Which of the following investigations would be most appropriate at this point for this patient?

- 1- Coronary angiography
- 2- Echocardiography
- 3- Endoscopy
- 4- Exercise ECG
- 5- Troponin T

Answer & Comments

Answer: 5- Troponin T

This question tests your knowledge of the initial management and investigation of chest pain, which is something you will need to be fully aware of for the exam and clinical practice.

This gentleman has a number of risk factors for acute coronary syndrome: he is a smoker and has a strong family history of ischaemic heart disease (IHD). The history he gives would be consistent with cardiac chest pain.

As you will all know, acute coronary syndrome and angina have a poor prognosis and it is therefore important to diagnose it accurately in a prompt fashion. It is important to distinguish between suspected acute coronary syndrome (ACS) and stable angina as the management differs markedly. 'Acute coronary syndrome' includes unstable angina,

ST-segment elevation myocardial infarction (STEMI) and non-ST-segment elevation myocardial infarction (NSTEMI).

Symptoms which may indicate ACS include:

- Pain in the chest and/or other areas (e.g. arms, back or jaw) lasting longer than 15 minutes
- Chest pain associated with nausea and vomiting, marked sweating, breathlessness, haemodynamic instability or particularly a combination of these
- New onset chest pain, or abrupt deterioration in previously stable angina, with recurrent chest pain occurring frequently and with little or no exertion, and with episodes often lasting longer than 15 minutes

Response to glyceryl trinitrate (GTN) should not be used to make the diagnosis. Symptoms do not present differently between sexes, or ethnic groups.

Patients who present with acute chest pain should have a 12-lead ECG as soon as possible. A normal ECG does not exclude acute coronary syndrome.

If the resting 12-lead ECG shows regional ST-segment elevation or presumed new left bundle block local protocols should be followed, which will often be to send these patients for immediate primary percutaneous coronary intervention (PCI).

Patients whose ECG shows regional ST-segment depression, deep T-wave inversion or Q waves (known or presumed to be new) suggestive of an NSTEMI or unstable angina should be treated as acute coronary syndrome immediately and a 12 hour troponin done for diagnostic and prognostic purposes.

If the resting 12-lead ECG is normal ACS should not be excluded. Serial resting ECGs should be taken and any new changes acted upon.

Management of ACS should be started as soon as suspected. Pain relief should be given in the form of GTN (sublingual or buccal) and/or intravenous opioids. 300mg aspirin should be given to all, unless there is clear evidence of an allergy. Other antiplatelet agents are given dependent on local policy, and the presence of ECG changes.

Supplemental oxygen should only be given to those with saturations of less than 94%, who are not at risk of hypercapnic respiratory failure (target saturations 94-98%, 88-92% in those with COPD who are at risk of hypercapnic respiratory failure).

Full bloods should be done on admission to hospital, including a baseline troponin (I or T). This troponin is not used immediately for interpretation of the cause of chest pain, but can be used to show a rise in patients who have an elevated baseline troponin (for example those with renal impairment).

A second blood sample is taken for troponin I or T 10-12 hours after the onset of symptoms. A myocardial infarct can be diagnosed when there is a rise and/or fall of troponin (with at least one value above the 99th percentile of the upper reference limit) together with evidence of myocardial ischaemia (symptoms, new ST changes/LBBB/new Q waves, imaging demonstrating new loss of myocardium or regional wall motion abnormality).

You should be aware that there are other causes of raised troponin, including myositis, aortic dissection and pulmonary embolism.

Patients who give a good history for cardiac chest pain, but their troponin is negative, should be investigated for stable chest pain. It is in these patients where an exercise test is useful to determine the presence of ischaemia on exertion.

Cardiac angiography is indicated in those patients who have a positive exercise test, or who have had a NSTEMI or unstable angina. The timing is determined by individual risk

factors, but a troponin is always determined prior to considering angiography (except of course with STEMI).

[Q: 1782] OnExamination 2012 - Cardiology

Which one of the following cardiac enzymes would be expected to begin to increase between 12-24 hours after a myocardial infarction?

- 1- Aspartate transaminase (AST)
- 2- Creatine kinase (CK)
- 3- LDH
- 4- Troponin I
- 5- Troponin T

Answer & Comments

Answer: 1- Aspartate transaminase (AST)

AST starts to rise after 12 to 24 hours and lactate dehydrogenase (LDH) after five days.

CK begins to rise after four hours, as do troponins although the troponins are far more specific.

[Q: 1783] OnExamination 2012 - Cardiology

Primary prevention trials for the treatment of hypercholesterolaemia reveal a reduction in all-cause mortality following treatment with which of the following?

- 1- Fibrates
- 2- Fish oils
- 3- Nicotinic acid
- 4- Resins
- 5- Statins

Answer & Comments

Answer: 5- Statins

Primary prevention refers to the prevention of cardiovascular disease in subjects without pre-existing ischaemic heart disease (IHD).

Although many lipid-lowering agents have demonstrated reductions in cardiovascular mortality, the question refers to all-cause mortality.

WOSCOPS (pravastatin) and AFCAPS-TexCAPS (lovastatin) demonstrated reductions in overall mortality, not just cardiovascular mortality, following treatment with statins.

None of the other agents are proven to reduce all-cause mortality in primary prevention.

Fibrates are however well proven in secondary prevention trials (BECAIT, VA-HIT).

[Q: 1784] OnExamination 2012 - Cardiology

1. Aorta
2. Aortic valve
3. Left atrium
4. Left ventricle
5. Right atrium
6. Right ventricle
7. Mitral valve
8. Pulmonary artery
9. Pulmonary valve
10. Pulmonary vein
11. Tricuspid valve
12. Vena cava

In which order does blood flow through a normal heart?

- 1- 12-5-11-6-9-8-10-3-7-4-2-1
- 2- 12-5-11-6-8-9-10-3-7-4-2-1
- 3- 12-5-11-6-9-10-8-3-7-4-2-1
- 4- 12-5-7-6-9-8-10-3-11-4-2-1
- 5- 12-3-11-4-9-8-10-5-7-6-2-1

Answer & Comments

Answer: 1- 12-5-11-6-9-8-10-3-7-4-2-1

Understanding the relationship of the different parts of the heart can be made easy by following the blood trajectory - this knowledge will help you understand how certain drugs that work on one part of the heart can help with a problem in another part of the heart, and also help you diagnose certain problems (such as valve defects and the symptoms associated with it).

After circulating around the body, the blood is brought back to the heart by the (superior and inferior) vena cava.

It then passes into the right atrium, through the tricuspid valve into the right ventricle.

From there, it travels via the pulmonary valve into the pulmonary artery (remember, blood always leave the heart via an artery), through the lungs, back into the heart via the pulmonary vein and into the left atrium.

It then passes the mitral valve to enter the left ventricle, and exits into the aorta via the aortic valve.

All this movement is regulated by synchronised contraction of the myocardium (muscular part of the heart).

[Q: 1785] OnExamination 2012 - Cardiology

In a trial of a new drug the following results were obtained:

	Improved	Not improved
Treatment group	44	16
Placebo group	36	26

Which of the following statements regarding the statistical analysis or interpretation of the trial is true?

1- A Student's t test could be used

- 2- Pearson's co-efficient of linear regression would be an appropriate significance test
- 3- The data could be evaluated using the chi-square test
- 4- The numbers are too small to draw any conclusions
- 5- The results so obviously show the benefit of treatment that statistical analysis is not required

Answer & Comments

Answer: 3- The data could be evaluated using the chi-square test

These data would be ideal for a chi-square test. It is a 2 x 2 contingency table for which there is a special chi-squared formula that gives a value that can be looked up in a table giving the p value.

The Student's t test cannot be used as we are comparing proportions not means.

Pearson's co-efficient cannot be calculated as there is no linear regression to plot.

Nothing is ever so obvious that no statistical analysis is needed.

[Q: 1786] OnExamination 2012 - Cardiology

On auscultation of a patient's heart you hear a pan-systolic murmur.

With which of the following conditions is this murmur associated?

- 1- Aortic regurgitation
- 2- Coarctation of the aorta
- 3- Mitral stenosis
- 4- Pulmonary stenosis
- 5- Ventricular septal defect

Answer & Comments

Answer: 5- Ventricular septal defect

A pansystolic or holosystolic murmur extends from the first heart sound through to the second heart sound which is often hard to hear because of the murmur.

It is seen in septal defects and, more commonly, mitral regurgitation.

[Q: 1787] OnExamination 2012 - Cardiology

Which of the following mechanisms best explains the action of fibrates?

- 1- Bile acid sequestration
- 2- Decreases hepatic cholesterol synthesis
- 3- Increased lipoprotein lipase activity via PPAR-alpha
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 3- Increased lipoprotein lipase activity via PPAR-alpha

The effect of fibrates on the metabolism of triglyceride-rich lipoproteins is due to a PPAR-alpha-dependent stimulation of lipoprotein lipase and of apolipoprotein (apo)A-V and to an inhibition of apoC-III expression, whereas the increase in plasma HDL-cholesterol depends partly on an overexpression of apoA-I and apoA-II.

Reference:

Drugs Today (Barc). 2006 Jan;42(1):39-64

[Q: 1788] OnExamination 2012 - Cardiology

A 54-year-old obese man with a history of angina and hypertension presents with central crushing chest pain of two hours duration.

High flow oxygen, sublingual GTN and aspirin are administered and venous access is obtained. Whilst being attached to an ECG

monitor he collapses, with a doctor present, and the initial rhythm is pulseless ventricular tachycardia (VT). The external defibrillator is located two minutes away on another ward.

Which of the following is the most appropriate immediate treatment for this man?

- 1- A ventilation to compression ratio of 30:2 should be commenced
- 2- Await arrival of defibrillator, then deliver shock
- 3- Continuous chest compressions should be started
- 4- He should be given a precordial thump
- 5- Intravenous adrenaline should be given

Answer & Comments

Answer: 4- He should be given a precordial thump

The 2010 ALS guidelines state that if a patient has a monitored and witnessed VF/VT arrest in hospital, three quick successive (stacked) shocks should be given. Chest compressions should be started immediately after the third, with a compression to ventilation ratio of 30:2 for 2 minutes.

A precordial thump can be successful if given within seconds of the onset of a shockable rhythm. Delivery should not delay calling for help, or accessing a defibrillator, but would be indicated here whilst awaiting the defibrillator. Chest compressions should start immediately if it is unsuccessful.

Intravenous adrenaline would be given every 3-5 minutes once chest compressions had started.

[Q: 1789] OnExamination 2012 - Cardiology

A 50-year-old man with hypertension already on furosemide, ramipril and digoxin is found to have poor left ventricular function on echocardiogram.

Which antihypertensive should be added?

- 1- Carvedilol
- 2- Diltiazem
- 3- Doxazosin
- 4- Hydralazine
- 5- Nifedipine

Answer & Comments

Answer: 1- Carvedilol

This patient has hypertension and reduced ejection fraction on echo indicating an element of failure.

In these circumstances the most appropriate agent with evidence to support its use for reducing morbidity and mortality in failure would be the addition of a β -blocker.

[Q: 1790] OnExamination 2012 - Cardiology

A 26-year-old professional footballer collapses while playing football. He is rushed to the Emergency department, and is found to be in ventricular tachycardia.

He is defibrillated successfully and his 12 lead ECG demonstrates normal sinus rhythm, without ST segment changes.

Ventricular tachycardia recurs and despite prolonged resuscitation, he dies.

What is the most likely diagnosis?

- 1- Aortic stenosis
- 2- Cocaine intoxication
- 3- Hypertrophic cardiomyopathy
- 4- Myocardial infarction
- 5- Pulmonary embolism

Answer & Comments

Answer: 3- Hypertrophic cardiomyopathy

The history of sudden arrhythmia in a young, previously well, individual is suggestive of

hypertrophic cardiomyopathy; relatives should be screened for the condition.

There is no history to suggest drug abuse; aortic stenosis is rare in the absence of congenital or rheumatic heart disease.

A myocardial infarction and massive pulmonary embolism would have given electrocardiogram (ECG) changes.

[Q: 1791] OnExamination 2012 - Cardiology

A 17-year-old girl is short in stature for her age. She has not shown any changes of puberty. She has a webbed neck.

Her vital signs include temperature 36.6°C, respiratory rate 18/min, pulse 75 bpm and BP 165/85 mmHg.

On physical examination, she has a continuous murmur heard over both the front of the chest as well as her back. Her lower extremities are cool with poor capillary filling.

A chest radiograph reveals a prominent left heart border, no oedema or effusions, and rib notching.

Which of the following pathologic lesions best explains these findings?

- 1- Constriction of the aorta past the ductus arteriosus
- 2- Lack of development of the spiral septum and partial absence of conus musculature
- 3- Shortening and thickening of chordae tendineae of the mitral valve
- 4- Single large atrioventricular valve
- 5- Supravalvular narrowing in the aortic root

Answer & Comments

Answer: 1- Constriction of the aorta past the ductus arteriosus

She has coarctation of the aorta, and the constriction is postductal, allowing prolonged survival.

Her physical characteristics also suggest Turner syndrome (monosomy X).

[Q: 1792] OnExamination 2012 - Cardiology

A 75-year-old man with a history of anterior MI is taking amiodarone 400 mg/day for history of VT. He has a prolonged QT interval on his ECG.

What is the most appropriate management?

- 1- Admit to hospital for monitoring
- 2- Atenolol
- 3- Change amiodarone to flecainide
- 4- Continue with amiodarone
- 5- Discontinue amiodarone immediately

Answer & Comments

Answer: 5- Discontinue amiodarone immediately

In iatrogenic long QT, which is what this is likely to be, it is safer to stop the offending drug rather than add further drugs on board (for example, β -blockers even though atenolol is used for long QT).

Flecainide is contraindicated in this situation (CAST study).

[Q: 1793] OnExamination 2012 - Cardiology

A 60-year-old man with a past history of controlled hypertension presents with acute onset weakness of his left arm, that resolved over 12 hours. He had suffered two similar episodes over the last three months.

Examination reveals a blood pressure of 132/82 mmHg and he is in atrial fibrillation with a ventricular rate of 85 per minute. CT brain scan is normal.

What is the most appropriate management?

- 1- Amiodarone

- 2- Aspirin
- 3- Digoxin
- 4- Dipyridamole
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

This patient has had three transient ischaemic attacks in the setting of atrial fibrillation. Compared to a person in sinus rhythm, a patient with atrial fibrillation has a fivefold increased risk of stroke (largely due to the increased risk of atrial thrombosis which can embolise to the brain). Stroke mortality is also higher than those without atrial fibrillation. Assessment is therefore given with regard to the need for anticoagulation.

Lower risk patients, as calculated by the CHADS₂-VASC score <2, do not need antithrombotic prophylaxis. They have a low annual risk of stroke, which is not significantly reduced by either warfarin or aspirin. Aspirin may be considered if there are other indications (for example, ischaemic heart disease or peripheral arterial disease).

CHADS₂-VASC Score:

Heart failure or ejection fraction <35% : 1

Hypertension: 1

Age: 65-74 years: 1, more than 75 years: 2

Diabetes: 1

Stroke, TIA or systemic emboli: 2

Vascular disease (previous MI, peripheral arterial disease, aortic plaque): 1.

Higher risk patients (CHADS₂-VASC 2+, annual stroke rate over 3%) should be considered for warfarin at a target INR of 2.5. Warfarin has been shown to have a relative risk reduction for stroke of 68% and death 33%. The minimum risk of stroke has been shown to occur in the INR range 2.0-3.0. There is an excess of two intracranial bleeds per year per thousand patients treated, usually associated

with an INR greater than 3 and uncontrolled hypertension.

There are however contraindications to warfarin, which include increased risk of bleeding, poor compliance and recurrent falls. Aspirin can be used as an alternative in these patients. Although less effective (20% relative risk reduction of stroke) it is simpler and less hazardous.

Cardioversion is indicated in select patients with AF, but there is a risk of systemic thromboembolism for those who have been in AF for more than two weeks. Patients with very recent onset AF require immediate assessment and treatment with heparin. If it is certain the AF has been present for two days or less, cardioversion can be attempted (electrical or pharmacological). Warfarin is not required if cardioversion is successful. If present for more than two days, warfarin is given for three weeks before cardioversion is attempted, and continued for at least four weeks following. Continuing warfarin should be considered for patients at high risk of recurrence (large left atrium, poor left ventricular function, hypertension) or previously symptomatic AF.

The most appropriate therapeutic strategy for this patient would be warfarin due to his high CHADS₂-VASC score. It is important to note, however, that anticoagulant therapy after an acute cerebral ischaemic event should be delayed until most of the deficit has resolved, or more than two weeks has elapsed for more severe strokes.

Digoxin may be indicated as a rate control agent, but will not reduce the risk of subsequent stroke. In the context of cerebrovascular disease, dipyridamole is only indicated if clopidogrel and/or aspirin are not tolerated.

[Q: 1794] OnExamination 2012 - Cardiology

A 27-year-old fit and healthy male has an ECG as part of his medical examination for employment as a pilot. The ECG reveals delta waves, indicating Wolff-Parkinson-White syndrome.

What is the most appropriate treatment for this patient?

- 1- Atenolol
- 2- Flecainide
- 3- Radio-frequency ablation
- 4- Reassurance
- 5- Verapamil

Answer & Comments

Answer: 4- Reassurance

[Q: 1795] OnExamination 2012 - Cardiology

A 37-year-old female patient who is undergoing treatment for breast cancer is admitted to the acute medical assessment unit with a seven day history of increasing breathlessness.

On examination she looks breathless. Her JVP is elevated with prominent "x" and "y" descents. The heart sounds are soft. A 12 lead ECG shows low voltage complexes.

Transthoracic echocardiography shows pericardial thickening with a restrictive Doppler pattern.

With regard to the investigation findings, what is the most likely cause of this patient's pericardial disease?

- 1- Dermatomyositis
- 2- Mediastinal irradiation
- 3- Scleroderma
- 4- SLE
- 5- Uraemia

Answer & Comments

Answer: 2- Mediastinal irradiation

All the options listed here are causes of pericardial disease.

The echo findings in this case are strongly suggestive of constrictive pericarditis where dense fibrous tissue replaces the normal pericardium.

Common causes include irradiation, TB and any cause of purulent pericarditis.

Therefore the correct answer is B.

[Q: 1796] OnExamination 2012 - Cardiology

A 67-year-old man presents to the Emergency department with uncontrolled nausea and vomiting.

He has a long history of COPD for which he takes high dose Seretide and theophylline tablets and has recently been prescribed some antibiotics by his GP for an exacerbation.

On examination his BP is 142/72 mmHg, his pulse is 92 and regular. Auscultation of the chest reveals wheeze and coarse crackles.

Investigations show:

Haemoglobin 13.4 g/dl(13.5-17.7)

White cell count $7.1 \times 10^9/L$ (4-11)

Platelets $172 \times 10^9/L$ (150-400)

Sodium 137 mmol/l (135-146)

Potassium 3.0 mmol/l (3.5-5)

Creatinine 115 $\mu\text{mol/l}$ (79-118)

Which of the following antibiotics is he most likely to have been prescribed?

- 1- Amoxicillin
- 2- Azithromycin
- 3- Cefuroxime
- 4- Clarithromycin
- 5- Doxycycline

Answer & Comments

Answer: 4- Clarithromycin

This patient is showing symptoms of theophylline toxicity, and the most likely cause of toxicity is co-prescription of a CYP3A4 inhibitor. Of the options listed, only clarithromycin is a potent 3A4 inhibitor. Azole antibiotics, amiodarone, fluoxetine and cimetidine are other examples.

Azithromycin is a macrolide but is not a significant inhibitor of 3A4. Whilst case reports exist of azithromycin precipitating drug accumulation it is much less likely to do so than clarithromycin or erythromycin.

Amoxicillin, doxycycline and cephalosporins should not lead to theophylline accumulation.

[Q: 1797] OnExamination 2012 - Cardiology

For which of the following are β blockers not recommended as first line therapy?

- 1- Chronic heart failure
- 2- Hypertension
- 3- Angina
- 4- Myocardial infarction
- 5- Permanent atrial fibrillation with rapid ventricular rate

Answer & Comments

Answer: 2- Hypertension

In its 2006 guidelines the National Institute for Health and Clinical Excellence (NICE) advise against using β -blockers as routine first line therapy for uncomplicated hypertension.

Review of several randomised controlled trials suggested that first line β -blockers were not as good at decreasing mortality as other classes of antihypertensive drugs and were less well tolerated.

Reference:

*B-blockers for hypertension currently published in
The Cochrane Database of Systematic Reviews
2010 Issue 11*

[Q: 1798] OnExamination 2012 -
Cardiology

Which of the following mechanisms best explains the action of simvastatin?

- 1- Activates PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 3- Decreases hepatic cholesterol synthesis

Most circulating cholesterol is manufactured internally, in amounts of about 1000 mg/day, via carbohydrate metabolism through the HMG-CoA reductase pathway.

Statins act by competitively inhibiting HMG-CoA reductase, the first committed enzyme of the HMG-CoA reductase pathway.

[Q: 1799] OnExamination 2012 -
Cardiology

A 50-year-old man is being treated for hypertension and has been told by his dentist that he has gingival hyperplasia.

Which of the following medications is the most likely to be the cause?

- 1- Atorvastatin
- 2- Carvedilol
- 3- Doxazosin
- 4- Nifedipine
- 5- Telmisartan

Answer & Comments

Answer: 4- Nifedipine

Three drugs to remember that are associated with gingival hyperplasia are phenytoin, ciclosporin and nifedipine.

[Q: 1800] OnExamination 2012 -
Cardiology

A 65-year-old is investigated for dyspnoea and is shown to have an ejection fraction of 45% on echocardiography.

How is left ventricular ejection fraction calculated?

- 1- Cardiac output/stroke volume
- 2- End diastolic volume/end systolic volume
- 3- End diastolic volume/stroke volume
- 4- End systolic volume/end diastolic volume
- 5- Stroke volume/end diastolic volume

Answer & Comments

Answer: 5- Stroke volume/end diastolic volume

The left ventricle pumps only a fraction of the blood it contains.

The ejection fraction is the amount of blood pumped (stroke volume = end diastolic volume - end systolic volume) divided by the amount of blood the ventricle contains (end diastolic volume).

A normal ejection fraction is more than 55% of the blood volume.

[Q: 1801] OnExamination 2012 -
Cardiology

A 42-year-old male admitted with dyspnoea is noted to have a murmur suggestive of mitral stenosis.

The presence of which of the following clinical signs suggests that the mitral valve is mobile?

- 1- A soft first heart sound
- 2- A third heart sound
- 3- Fourth heart sound
- 4- Loud second heart sound
- 5- Opening snap

Answer & Comments

Answer: 5- Opening snap

Features of mitral stenosis include the loud first heart sound, opening snap and if in sinus rhythm, a pre-systolic accentuation.

Calcification of the valve results in immobility and loss of the opening snap.

[Q: 1802] OnExamination 2012 - Cardiology

A 72-year-old man is admitted with fast atrial fibrillation but is receiving treatment with digoxin. An inadequate dose is suspected. A sample of blood is drawn six hours after the last dose of digoxin and a plasma concentration is requested.

Which of the following factors explains the six hour wait before measuring the digoxin concentration?

- 1- Enterohepatic circulation
- 2- The rate of absorption
- 3- The rate of clearance
- 4- The rate of distribution
- 5- The rate of elimination

Answer & Comments

Answer: 4- The rate of distribution

A blood sample needs to be drawn at least six hours after administration of digoxin to ensure adequate distribution. A useful link discussing some of the pharmacodynamics of Digoxin and the relevance of monitoring can be viewed in this pdf file.

[Q: 1803] OnExamination 2012 - Cardiology

Which of the following findings is the most specific for a diagnosis of myocardial infarction?

- 1- An akinetic area of LV wall motion on ECHO
- 2- Elevated cardiac enzymes
- 3- Evolution of Q waves on ECG
- 4- History of severe chest pain
- 5- ST elevation on ECG

Answer & Comments

Answer: 3- Evolution of Q waves on ECG

Cardiac enzymes may be elevated in pulmonary embolism (PE), renal failure and raised ST segments associated with pericarditis.

Akinetic wall motion on the echo may occur with any regional disease process like amyloid, etc.

The evolution of Q waves is the most suggestive of an infarct.

[Q: 1804] OnExamination 2012 - Cardiology

A 17-year-old female is found to have a cardiac murmur characterised by a mid-systolic click.

An echocardiogram reveals mitral insufficiency with upward displacement of one leaflet. There is also aortic root dilation to 4 cm. She has a dislocated right ocular crystalline lens. She dies suddenly and unexpectedly.

The medical examiner finds a prolapsed mitral valve with elongation, thinning, and rupture of chordae tendineae.

A mutation involving which of the following genes is most likely have be present in this patient?

- 1- Beta-myosin

- 2- CFTR
- 3- FGFR
- 4- Fibrillin
- 5- Spectrin

Answer & Comments

Answer: 4- Fibrillin

Marfan syndrome is a connective tissue disorder that is associated with floppy mitral valve and also with cystic medial necrosis that predisposes to aortic dissection.

Abnormalities of the beta-myosin gene may be associated with some forms of dilated cardiomyopathy.

The CFTR gene is associated with cystic fibrosis.

The obstructive lung disease from widespread bronchiectasis that results from cystic fibrosis involving the lung can lead to pulmonary hypertension with cor pulmonale.

The fibroblast growth factor receptor (FGFR) gene mutations can be associated with skeletal dysplasias.

The spectrin gene mutation can be associated with red cell membrane abnormalities associated with hereditary spherocytosis.

Anaemias in adults with this condition are not typically severe, though anaemias in general can increase cardiac stress.

[Q: 1805] OnExamination 2012 - Cardiology

A randomised, double-blind, placebo controlled trial of a cholesterol-lowering drug in the primary prevention of coronary heart disease is reported.

1000 subjects are treated with the active drug, and 1000 are given placebo. They are followed up over a five year period and 100 individuals

in the placebo group and 80 in the treatment group suffer a myocardial infarction (MI).

What is the annual percentage risk of myocardial infarction in the group treated with placebo?

- 1- 0.5%
- 2- 2%
- 3- 5%
- 4- 8%
- 5- 10%

Answer & Comments

Answer: 2- 2%

In the five years 100 patients in the placebo group develop an MI.

Assuming this is spread evenly across the years this means that 20 patients (out of 1000) suffer an MI each year.

The annual risk is therefore $20/1000 = 0.02$ which, expressed as a percentage is 2.

[Q: 1806] OnExamination 2012 - Cardiology

You have shown an interest in paediatric cardiology and your clinical supervisor has arranged for you to attend some clinics with the visiting paediatric cardiologist.

You have a very interesting session and you were particularly interested in the patients you saw with ventricular septal defects (VSDs). After this session you have been stimulated to do some self-directed learning and want to read about VSDs. As part of your reading you learn about the anatomical classification of VSDs and the frequency of each type.

During your reading, what did you discover to be the most common site for a VSD?

- 1- Muscular - inlet
- 2- Muscular - outlet
- 3- Muscular - trabecular

- 4- Perimembranous
5- None of the above

Answer & Comments

Answer: 4- Perimembranous

There are a number of different classifications for VSDs.

One easy way to group these is based on the division of the ventricular septum into membranous and muscular portions.

Options A, B and C are the subdivision of the muscular VSDs and occur in 5%, 5-10% and 5-10% respectively.

Perimembranous VSDs account for 70-80% of VSDs and are situated between the inlet and outlet portions of the septum.

[Q: 1807] OnExamination 2012 - Cardiology

An 84-year-old female with permanent atrial fibrillation, ischaemic heart disease with well preserved left ventricular systolic function and mild COPD is due elective surgery for a large abdominal aortic aneurysm.

Choose the most appropriate drug from the list to reduce peri-operative cardiac risk in this patient.

- 1- Atenolol
2- Carvedilol
3- Metoprolol
4- Oxprenolol
5- Sotalol

Answer & Comments

Answer: 1- Atenolol

The ESC guidelines in 2009 for peri-operative management of patients undergoing high risk vascular surgery recommends prophylactic β -blockers for high risk vascular surgery (including those patients with COPD).

Bisoprolol is probably the best clinical choice in this case, but is not on the list.

Atenolol is the best choice from this list - it is cardio-selective and long acting - reducing risk of postoperative myocardial ischaemia and tachycardia.

Carvedilol is non-selective and so has greater risk of exacerbating COPD.

Oxprenolol is undesirable because of its intrinsic sympathomimetic properties.

Metoprolol though selective is shorter acting.

Sotalol may be appropriate for paroxysmal AF, but not permanent AF.

[Q: 1808] OnExamination 2012 - Cardiology

A 16-year-old female attends casualty 15 hours after ingesting approximately 30 g of paracetamol and 2 g of dihydrocodeine.

On examination, she is drowsy with a Glasgow coma scale of 15. Her pulse is 100 beats per minute, blood pressure is 110/66 mmHg and she has pinpoint pupils, with saturations of 96% on air.

What is the most appropriate treatment for this patient?

- 1- 10% Dextrose infusion
2- Activated charcoal by mouth
3- Gastric lavage
4- N-acetylcysteine intravenously
5- Naloxone intravenously

Answer & Comments

Answer: 4- N-acetylcysteine intravenously

This patient has taken a significant overdose of paracetamol, and is presenting late at 15 hours.

She is at risk of hepatocellular damage and needs to be commenced on an infusion of

intravenous N-acetylcysteine immediately. It is continued for 30 hours and sometimes beyond this, depending on results of prothrombin time, liver function tests, urea and electrolytes, and glucose.

Activated charcoal is given to patients presenting within one hour of overdose.

Flumazenil is reserved for reversal of benzodiazepine-induced respiratory depression.

Naloxone is used for opiate-induced respiratory depression.

[Q: 1809] OnExamination 2012 - Cardiology

A 70-year-old man is admitted to the cardiology ward with a diagnosis of Streptococcus bovis infective endocarditis.

Which of the following investigations would be indicated?

- 1- Colonoscopy
- 2- Cystoscopy
- 3- Lymph node biopsy
- 4- Sialogram
- 5- Thoracoscopy

Answer & Comments

Answer: 1- Colonoscopy

The association between Streptococcus bovis bacteraemia and colonic neoplasia is well described.

The consensus of opinion is that all subjects should undergo evaluation including investigation of the gastrointestinal tract.

If investigation is clear then further tests should be performed only where there are symptoms or signs to suggest malignancy in other areas.

Reference:

Arch Surg. 2004;139:760-765

[Q: 1810] OnExamination 2012 - Cardiology

A 69-year-old man presents with sudden onset tearing chest pain that radiated through to his back.

He is sweaty. His BP is 140/90 mmHg and pulse 95 bpm. A CXR shows a widened mediastinum and CT scan confirms an aortic dissection of the descending aorta.

Which of the following is the most appropriate initial management of this patient?

- 1- Immediate surgical referral
- 2- IV labetalol
- 3- Observe on high dependency unit
- 4- Refer for cardiac catheterisation
- 5- Verapamil orally

Answer & Comments

Answer: 2- IV labetalol

Advances in the understanding of this disease have established that lesions limited to the descending aorta (type B) generally have better survival compared with those involving the ascending aorta.

Current recommendations support the use of betablockers as the initial management with an increasing number of endovascular and surgical techniques being used as local expertise dictates.

Reference:

Circulation. 2003;108:II-312

[Q: 1811] OnExamination 2012 - Cardiology

A 34-year-old male presents with palpitations. The ECG shows a slurred upstroke in the QRS complexes in the chest leads.

What is the treatment of choice?

- 1- Amiodarone
- 2- Aspirin

- 3- Diltiazem
- 4- Radiofrequency ablation
- 5- Warfarin

Answer & Comments

Answer: 4- Radiofrequency ablation

This patient has Wolff-Parkinson-White syndrome as suggested by the delta wave on ECG.

Anticoagulation is not indicated.

Risk of arrhythmia after ablation is of the order of 7% over five years.

[Q: 1812] OnExamination 2012 - Cardiology

A 35-year-old female presents with chest pain on exertion.

On examination she has yellow discolouration of her palmar creases and a diagnosis of remnant hyperlipidaemia (type III hyperlipidaemia) is made.

What is the cause of this hyperlipidaemia?

- 1- Apo CIII homozygosity
- 2- Apo E-2 homozygosity
- 3- LCAT deficiency
- 4- LDL receptor deficiency
- 5- Lipoprotein lipase deficiency

Answer & Comments

Answer: 2- Apo E-2 homozygosity

Remnant hyperlipidaemia is associated with:

Hypercholesterolaemia
Hypertriglyceridaemia
Palmar xanthomata

Early onset of cardiovascular disease.

The genotype of the condition is apo E-2/E-2 and occurs with a frequency of 1:100.

Low density lipoprotein (LDL) receptor deficiency is associated with familial hypercholesterolaemia.

Lipoprotein lipase deficiency is rare and associated with marked hypertriglyceridaemia.

[Q: 1813] OnExamination 2012 - Cardiology

A 60-year-old man takes atenolol for hypertension.

Which of the following side effects is he most likely to be aware of two hours after taking atenolol?

- 1- Fatigue
- 2- Hesitancy of micturition
- 3- Nausea
- 4- Orthostatic hypotension
- 5- Somnolence

Answer & Comments

Answer: 1- Fatigue

Atenolol is a water soluble β -blocker, taken once daily and is not associated with drowsiness/sleep disturbance like the lipid-soluble β -blockers.

It is not associated with nausea or hesitancy of micturition and would be unlikely to produce significant postural hypotension in a hypertensive subject.

However, fatigue is a frequent side effect which typically is felt two hours and beyond after taking the drug.

[Q: 1814] OnExamination 2012 - Cardiology

A 30-year-old man presented with a history of transient loss of consciousness and palpitation. His ECG showed ventricular tachycardia (VT).

Which one of the following treatments should be avoided?

- 1- Adenosine
- 2- Amiodarone
- 3- DC cardioversion
- 4- Flecainide
- 5- Verapamil

Answer & Comments

Answer: 5- Verapamil

Verapamil may cause fatal hypotension in VT (due to negative inotropic and peripheral vasodilatory effects).

Flecainide should be used with caution because it may produce an incessant form of VT which is difficult to control.

Adenosine is used to differentiate supraventricular tachycardia (SVT) with right (or left) bundle branch block from VT.

[Q: 1815] OnExamination 2012 - Cardiology

A 65-year-old man was advised to start oral digoxin at a dose of 250 µg daily. His physician explained that the full effect of this treatment would not be apparent for at least a week.

Which one of the following pharmacokinetic variables did the physician use to give this explanation?

- 1- Bioavailability
- 2- Half life
- 3- Plasma protein binding
- 4- Renal clearance
- 5- Volume of distribution

Answer & Comments

Answer: 2- Half life

Digoxin follows first order kinetics and has a half life of 1.6 days in a patient with normal renal function.

Sixty five per cent of the drug absorbed remains in the system after one day.

Subsequent doses gradually accumulate until a steady state is achieved after four to five days.

[Q: 1816] OnExamination 2012 - Cardiology

Which of the following antimicrobials is associated with prolongation of the QT interval?

- 1- Cefuroxime
- 2- Co-amoxiclav
- 3- Erythromycin
- 4- Gentamicin
- 5- Isoniazid

Answer & Comments

Answer: 3- Erythromycin

The macrolides are associated with a prolongation of the QT interval.

Other antimicrobials associated with prolonged QT include quinine and levofloxacin.

[Q: 1817] OnExamination 2012 - Cardiology

Your next patient in the care of the elderly clinic is a 77-year-old man with a history of hypertensive heart disease leading to congestive cardiac failure.

Unfortunately, in the past few months his symptoms have worsened and he is becoming house bound. His wife accompanied him and is worried about his state. She asks you directly 'how long has he got left'. You tell his wife that certain test results can suggest a worse prognosis.

From the list, which blood test result suggests a worse prognosis in heart failure?

- 1- Hypocalcaemia
- 2- Hyponatraemia
- 3- Low serum BNP/ NT-pro-BNP
- 4- Low serum uric acid
- 5- Polycythaemia

Answer & Comments

Answer: 2- Hyponatraemia

Heart failure is a chronic condition with a high morbidity and mortality.

There are a number of clinical features and biochemical parameters which provide useful prognostic information.

Prognostic markers include:

- High BNP/NT-pro-BNP
- Anaemia
- Hyponatraemia
- Increased uric acid.

Serum calcium is not a useful in prognosis in heart failure.

[Q: 1818] OnExamination 2012 - Cardiology

A male infant is rushed to the Emergency department by his parents with a short history of blue lips and breathlessness. His parents are frantic and you arrange admission to the paediatric ward.

Two days later you decide to go to the ward to see how the patient is doing. You look through the notes and find a report from a transthoracic echocardiogram. The report mentions displacement of the tricuspid valve towards the apex, a small 'atrialised' and hypoplastic RV, an ASD and tricuspid incompetence.

Based on the echo findings, what is the likely diagnosis?

- 1- Ebstein's anomaly
- 2- Hypoplastic left ventricle
- 3- Tetralogy of Fallot
- 4- Truncus arteriosus
- 5- None of the above

Answer & Comments

Answer: 1- Ebstein's anomaly

Ebstein's anomaly is congenital heart defect which has been linked with maternal lithium intake.

There is variable anatomy but the most common findings are a hypoplastic (atrialised) RV, apical displacement of the septal and posterior tricuspid valve leaflets, ASD.

Wolff-Parkinson-White syndrome occurs in around 15% of the patients.

Presentation depends on the extent of the defects and can be at any stage of childhood with heart failure or arrhythmias.

[Q: 1819] OnExamination 2012 - Cardiology

You are investigating the use of novel markers which may show myocardial damage within the first three hours after myocardial infarction to see if this may improve early diagnosis of damage.

Which of the following is the most appropriate marker?

- 1- CKMB
- 2- Glycogen phosphorylase isoenzyme BB (GPBB)
- 3- LDH
- 4- Troponin I
- 5- Troponin T

Answer & Comments

Answer: 2- Glycogen phosphorylase isoenzyme BB (GPBB)

GPBB is an isoenzyme of glycogen phosphorylase which exists in cardiac muscle. By three hours post myocardial infarction it has risen significantly. As such it is an appropriate marker for early cardiac muscle injury.

Troponin rises by hour six post-myocardial infarction and the steepest increase in troponin continues until around hour 12. Troponin assays are widely available and cost-effective and as such it is the investigation of choice for ischaemic chest pain.

Lactate dehydrogenase (LDH) rises late, some two to five days post-infarct.

[Q: 1820] OnExamination 2012 - Cardiology

A 62-year-old male is admitted with an inferior myocardial infarction (MI) and receives thrombolysis, aspirin, atenolol, simvastatin and lisinopril. His ECG shows good ST segment resolution.

The following day he develops some pain in the legs and a dusky discolouration of the lower limbs. On closer examination there is a diffuse petechial rash over the lower legs, particularly the feet, but all peripheral pulses are palpable.

Investigations reveal:

Haemoglobin 13.3 g/dl(12-16)

Platelets 145 x 10⁹/L (150-400)

White cell count 12.1 x 10⁹/L (4-11)

Neutrophils 6.5 x 10⁹/L (1.5-7)

Lymphocytes 3.5 x 10⁹/L (1.5-4)

Eosinophils 1.2 x 10⁹/L (0.04-0.4)

IgE antibody 3 kU/l (<2)

Which of the following is the most likely cause for his current problems?

- 1- Allergic reaction to thrombolysis
- 2- Aspirin allergy
- 3- Cholesterol emboli
- 4- Peripheral vascular disease
- 5- Polyarteritis nodosa

Answer & Comments

Answer: 3- Cholesterol emboli

This patient is an arteriopath as suggested by the acute MI, and one day after thrombolysis develops a petechial rash in the lower limbs with raised white cell count - marked eosinophilia and raised IgE.

Rather than allergy, this suggests cholesterol embolisation syndrome.

[Q: 1821] OnExamination 2012 - Cardiology

A 26-year-old female with a small ventriculo-septal defect (VSD) presents in the sixth week of pregnancy. She has been told that she would need antibiotic prophylaxis for dental surgery, and various other procedures.

She asks you to tell her whether she will have to take this during her pregnancy, and if so, at which point it will be needed.

- 1- Antibiotic prophylaxis is not indicated
- 2- At delivery
- 3- Onset of labour
- 4- Second trimester
- 5- Third trimester

Answer & Comments

Answer: 1- Antibiotic prophylaxis is not indicated

Infective endocarditis (IE) is a rare condition, but one which carries significant morbidity and mortality. It may arise following bacteraemia in any patient, but those with a predisposing cardiac lesion and at an

increased risk. In previous years, at risk patients have been given antibiotic prophylaxis before certain interventional procedures to reduce the risk of developing IE. However, in recent years the lack of a robust evidence base has led to this practice being questioned. In light of this, NICE issued guidance in 2008.

These guidelines highlight that the patients at risk of developing IE are those with:

acquired valvular heart disease (stenosis or regurgitation),
valve replacement,
structural congenital heart disease (including surgically corrected or palliated structural conditions, but excluding isolated atrial septal defect, fully repaired ventricular septal defect or fully repaired patent ductus arteriosus and closure devices that are judged to be endothelialised),
previous infective endocarditis,
hypertrophic cardiomyopathy.

In these patients any episodes of infection should be fully investigated and treated promptly to reduce the risk of endocarditis developing. However, prophylaxis is not recommended for undergoing dental procedures, or procedures at the following sites:

- upper and lower gastrointestinal tract,
- genitourinary tract (including childbirth),
- upper and lower respiratory tract (including ENT),

Chlorhexadine mouthwash is also not recommended.

The only recommendation for antibiotics is if an at-risk patient is undergoing a gastrointestinal or genitourinary procedure at a site where there is a suspected infection - in

these cases an antibiotic should be given that covers organisms that cause IE.

NICE Guidelines

[Q: 1822] OnExamination 2012 -
Cardiology

A 52-year-old lady presented with a history of crushing central chest pain, sweating and dyspnoea.

An ECG confirms acute myocardial infarction with ST elevation in leads V2-V4 and ST depression in leads II and III.

Which of the following would be a contraindication to thrombolysis in this lady?

- 1- History of peptic ulcer disease
- 2- Intracranial neoplasm
- 3- Menstruation
- 4- Pre-proliferative diabetic retinopathy
- 5- Ischaemic stroke 2 years previously

Answer & Comments

Answer: 2- Intracranial neoplasm

Contraindications to thrombolysis include:

Intracranial neoplasm as here
Ischaemic stroke within six months
Pregnancy
Active internal bleeding
Aortic dissection
Recent significant head injury
Severe and uncontrolled hypertension.

[Q: 1823] OnExamination 2012 -
Cardiology

A 57-year-old female school cleaner is undergoing investigation for breathlessness.

Which of the following is not in keeping with a diagnosis of constrictive pericarditis?

- 1- Ascites

- 2- Elevated JVP with absent y descent
- 3- Orthopnoea
- 4- Peripheral oedema
- 5- Previous cardiac surgery

Answer & Comments

Answer: 2- Elevated JVP with absent y descent

Constrictive pericarditis typically impedes late diastolic ventricular filling, which produces an elevated jugular venous pressure (JVP), with prominent x and y descent.

Pulsus paradoxus is a variable finding, unless a pericardial effusion with an abnormally elevated pressure exists.

Other signs include:

- Oedema
- Ascites
- Hepatomegaly
- Orthopnoea
- Dyspnoea.

Constrictive pericarditis may be a subtle cause of dyspnoea after cardiac surgery.

[Q: 1824] OnExamination 2012 - Cardiology

A 65-year-old woman presents with heart failure. Her echocardiogram shows a restrictive cardiomyopathy but with structurally normal valves.

Which one of the following is the most likely cause?

- 1- Amyloidosis
- 2- Coxsackie infection
- 3- Down's syndrome
- 4- Marfan's syndrome
- 5- Turner's syndrome

Answer & Comments

Answer: 1- Amyloidosis

The diagnosis is amyloidosis which typically causes an infiltrative restrictive cardiomyopathy in patients of this age group.

Other causes include:

- Sarcoidosis
- Radiotherapy
- Systemic sclerosis
- Carcinoid syndrome.

Coxsackie produces a viral myocarditis with the likelihood of a dilated appearance on echo.

Marfan's is likely to cause valvular regurgitant defects and a dilated cardiomyopathy.

Down's syndrome is more likely to be associated with AV canal defects and consequent dilatation.

Turner's syndrome is associated with atrial septal defects and coarctation and bicuspid valvular defects.

[Q: 1825] OnExamination 2012 - Cardiology

A 40-year-old man received an orthotopic cardiac transplant seven years ago to treat a dilated cardiomyopathy. Since that time he has been healthy, with no episodes of rejection or infection. Over the next year, however, he develops fatigue with exercise. He has worsening pedal oedema and orthopnoea.

On physical examination, his vital signs are temperature 36.3°C, pulse 78, respiratory rate 16, and BP 130/70 mm Hg. There are no murmurs, rubs, or gallops audible. Bibasilar crackles in the lungs are audible.

Which of the following conditions is most likely to account for these findings?

- 1- Angiosarcoma
- 2- Coronary arteriopathy
- 3- Mitral valvular stenosis
- 4- Myocarditis

5- Pulmonary hypertension

Answer & Comments

Answer: 2- Coronary arteriopathy

By five years following cardiac transplantation, nearly all patients have some degree of small coronary vascular narrowing.

Myocarditis is unlikely to be present in the absence of rejection or infection.

[Q: 1826] OnExamination 2012 - Cardiology

Which of the following is true regarding mitral stenosis?

- 1- Doppler U/S is usually inaccurate in determining severity
- 2- In AF, the opening snap disappears
- 3- It is tolerated well in pregnancy
- 4- The opening snap is not heard when the mitral valve is heavily calcified
- 5- There is characteristically a low wedge pressure

Answer & Comments

Answer: 4- The opening snap is not heard when the mitral valve is heavily calcified

Mitral stenosis is typically a consequence of childhood rheumatic fever, but congenital disease is well recognised.

It is associated with a tapping apex beat, a loud S1, opening snap and mid-diastolic rumble with pre-systolic accentuation in those in sinus rhythm.

The opening snap is characteristically lost with heavy valvular calcification.

In particular mitral stenosis is poorly tolerated in pregnancy due to volume overload.

It is well characterised by Doppler echocardiography.

[Q: 1827] OnExamination 2012 - Cardiology

Following a lecture on cardiac physiology, your consultant asks you during a ward round *to calculate how much blood (in ml) Mr. Smith's ventricle ejects every time his heart beats*. He gives you the following values:

Blood pressure: 136/90 mmHg units

Cardiac output: 5000 ml/minute

Heart Rate: 72/minute

Urine output: 5 ml/kg/hr

- 1- 5ml
- 2- 20ml
- 3- 50ml
- 4- 70ml
- 5- 130ml

Answer & Comments

Answer: 4- 70ml

Cardiac output (CO), or the volume of blood being pumped by the heart in one minute, is essential for normal function. It is a reflection of how well the rest of the body is being perfused, and therefore how well the body can work (perfusion enables energy production). It is multifactorial, and these can be calculated using stroke volume (SV) and heart rate (HR):

$$CO = HR \times SV$$

If 5000 ml is pumped in one minute, with 72 beats of the heart, each beat will pump around $5000/72 = 69.4$ ml.

This relationship can be seen at all times: indeed, when one of the parameters in the equation changes, the others change accordingly, to maintain the CO within a tight range.

In this situation, the blood pressure, and urine output were both useless information, as all that was needed was the cardiac output

(which in a normal adult ranges from 5-8 L/min), and the heart rate.

[Q: 1828] OnExamination 2012 - Cardiology

A young boy is born with a heart murmur that is subsequently diagnosed as Ebstein's anomaly.

Which of the following drugs, taken by the mother, may have contributed to this case of congenital heart disease?

- 1- Amiodarone
- 2- Carbimazole
- 3- Lithium
- 4- Phenytoin
- 5- Warfarin

Answer & Comments

Answer: 3- Lithium

Exposure to lithium in utero is associated with Ebstein's anomaly.

[Q: 1829] OnExamination 2012 - Cardiology

A 55-year-old man with type 2 diabetes mellitus and ischaemic heart disease has been researching the internet!

He asks your opinion on laser transmyocardial revascularisation.

Which of the following statements about this technique is true?

- 1- Avoids the need for major surgery
- 2- Damages the endocardium
- 3- Involves destruction of coronary stenoses
- 4- Is of particular use in severe proximal coronary artery disease
- 5- Stimulates collateral vessel formation

Answer & Comments

Answer: 2- Damages the endocardium

Open chest surgery is undertaken, during which laser holes are punched from the epicardial surface into areas of suspected ischaemic or hibernating ventricular muscle. The process is not fully understood.

The epicardial end of the hole heals up leaving artificial channels communicating with the ventricular chamber and effectively forming new coronary vessels.

Laser transmyocardial revascularisation has potential in distal disease such as in diabetes.

Angioplasty and coronary artery bypass graft (CABG) are useful in proximal disease.

[Q: 1830] OnExamination 2012 - Cardiology

A 27-year-old fit and healthy male has an ECG as part of his medical examination for employment as a pilot. The ECG reveals delta waves, indicating Wolff-Parkinson-White syndrome.

What is the most appropriate treatment for this patient?

- 1- Atenolol
- 2- Flecainide
- 3- Radio-frequency ablation
- 4- Reassurance
- 5- Verapamil

Answer & Comments

Answer: 4- Reassurance

WPW is a relatively common cardiological abnormality occurring in approximately 0.1 to 3% of the population.

It is due to an accessory pathway and although most subjects are asymptomatic, there is the small risk of sudden death from

tachyarrhythmias (<0.6%). Treatment is based on risk stratification.

One of the pointers is symptomatology, and also electrophysiological studies (EPS). Generally, in an asymptomatic individual it is uncertain whether any intervention or indeed any EPS is required.

Radiofrequency ablation is the treatment of choice in those identified to be at risk.

[Q: 1831] OnExamination 2012 - Cardiology

A 67-year-old male is admitted with central chest pain of sudden onset which radiates through to his back.

His blood pressure is 160/70 mmHg in his right arm and 140/60 mmHg in his left arm. He has electrocardiographic (ECG) changes in leads II, III and AVF showing ST elevation of 2 mm.

What is the most likely diagnosis?

- 1- Coarctation of the aorta
- 2- Dissecting thoracic aortic aneurysm
- 3- Inferior myocardial infarct
- 4- Pancreatitis
- 5- Perforated duodenal ulcer

Answer & Comments

Answer: 2- Dissecting thoracic aortic aneurysm

This history is suggestive of a dissecting thoracic aortic aneurysm.

The ECG changes of inferior myocardial infarct suggest that the aneurysm has dissected the right coronary artery at its ascending aortic ostium. An ascending aortic dissection needs immediate surgery. Whilst en route to surgery, beta-blockade to control hypertension is appropriate.

An inferior myocardial infarct is high in the differential - however thrombolysis will kill a patient with an aortic dissection.

Coarctation can give different blood pressures in either arm but is a chronic condition. Ulcer and pancreatitis may mimic a heart attack, but with a normal ECG.

[Q: 1832] OnExamination 2012 - Cardiology

A 52-year-old man attends a GP clinic. He has a strong family history of ischaemic heart disease, smokes 10 cigarettes per day and drinks approximately 20 units of alcohol per week.

On examination, he is obese with a BMI of 32 kg/m² and has a blood pressure of 152/88 mmHg.

His investigations reveal that he has a fasting plasma glucose of 10.5 mmol/L (3.0-6.0), HbA1c of 7.8% or 62 mmol/mol (range 3.8-6.4%; 18-46 mmol/mol) and his cholesterol concentration is 5.5 mmol/L (<5.2).

Which of the following would be expected to be most effective in reducing his cardiovascular risk?

- 1- Improve glycaemic control with metformin
- 2- Improve hypertensive control with ramipril
- 3- Reduce cholesterol with simvastatin
- 4- Stop smoking
- 5- Weight loss with Xenical

Answer & Comments

Answer: 4- Stop smoking

This patient has hypertension and is diabetic as suggested by the elevated fasting plasma glucose.

It has been established that:

Metformin has been shown to reduce CV mortality in obese diabetics (UKPDS)

Ramipril reduces CV risk in hypertensive diabetics (HOPE) and

Statins reduce CV mortality (4S, HPS).

However, none of these interventions are as effective as stopping smoking in reducing CV risk.

There is no evidence that non-surgical weight loss per se reduces CV mortality, although good studies are lacking.

Gastric bypass surgery reduces cardiovascular events.

[Q: 1833] OnExamination 2012 - Cardiology

An 80-year-old male presented with palpitations of five hours duration.

One month previously he suffered weakness of the right arm and problems with his speech which resolved within four hours. He was taking no medication.

On examination, he was stable with a pulse of 135 beats per minute which was confirmed to be atrial fibrillation on ECG. He had a blood pressure of 112/80 mmHg and appeared clinically euthyroid.

Within one hour he reverted to sinus rhythm spontaneously.

Echocardiogram was normal but a 24 hour ECG revealed three episodes of atrial fibrillation each lasting around ten minutes.

Which one of the following is the most appropriate initial treatment for this patient?

- 1- Amiodarone
- 2- Aspirin
- 3- Atenolol
- 4- Digoxin
- 5- Warfarin

Answer & Comments

Answer: 5- Warfarin

The most appropriate initial therapy for this patient who has a high risk of thrombo-embolic stroke is anticoagulation with

warfarin maintaining an international normalised ratio (INR) between 2-3.

This should be the initial priority as he has already had one episode of transient ischaemic attack (TIA).

The maintenance of sinus rhythm would be the next step and amiodarone or sotalol are options.

[Q: 1834] OnExamination 2012 - Cardiology

A 63-year-old woman is admitted to hospital with a three day history of diarrhoea and vomiting. Her family tell you she has been virtually unable to eat or drink, but has managed to take her tablets during that time.

Her past medical history includes essential hypertension and ischaemic heart disease. Her current medication consists aspirin 75 mg daily, ramipril 5 mg daily, simvastatin 40 mg daily.

Her admission bloods demonstrate:

Sodium 144 mmol/l 137 - 144

Potassium 4.1 mmol/l 3.5 - 4.9

Urea 10.8 mmol/l 2.5 - 7.5

Creatinine 195 µmol/l 60 - 110

Which of the following is most appropriate?

- 1- Double dose of ramipril
- 2- Give clopidogrel 300 mg stat
- 3- Give loperamide
- 4- Withhold aspirin
- 5- Withhold ramipril

Answer & Comments

Answer: 5- Withhold ramipril

The history is entirely consistent with gastroenteritis, and as a result of the protracted vomiting the patient has become dehydrated. In this context an ACE inhibitor (ramipril) is dangerous and should be stopped.

Within the kidneys the afferent and efferent arterioles take blood to (afferent) and from (efferent) the glomerulus.

ACE inhibitors work by decreasing the tone of the efferent arterioles, which in a euvolaemic patient can protect the kidney in hypertension, diabetes and other insults. However in a hypovolaemic patient (such as this patient) this can lead to catastrophic impairment of renal function.

[Q: 1835] OnExamination 2012 - Cardiology

A 52-year-old man presents to the clinic having problems controlling his blood pressure, despite taking three anti-hypertensive agents, ramipril 10 mg, indapamide 2.5 mg, and amlodipine 5 mg.

Over the past few weeks he has been monitoring his BP at home and it is rarely below 155/90 mmHg.

On examination in the clinic his BP is 160/95 mmHg, his pulse is 85 and regular. He has a left carotid bruit. Respiratory and abdominal examinations are unremarkable.

Investigations show:

Haemoglobin 12.0 g/dl (13.5-17.7)

White cells $6.3 \times 10^9/L$ (4-11)

Platelets $200 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (135-146)

Potassium 4.8 mmol/l (3.5-5)

Creatinine 182 $\mu\text{mol/l}$ (79-118)

Renal ultrasound scan showed significant size discrepancy, with the left kidney 2 cm smaller than the right.

Which of the following is the most appropriate next investigation?

- 1- Contrast CT
- 2- Duplex ultrasound scanning
- 3- IVU
- 4- Magnetic resonance angiogram

5- Traditional angiography

Answer & Comments

Answer: 2- Duplex ultrasound scanning

Duplex ultrasound scanning is both sensitive and specific for detection of renal artery stenosis but is only effective in the hands of a highly skilled technician.

Alternatives include contrast CT or MRA using gadolinium.

There is concern here, albeit low, that he may develop contrast nephropathy, and some commentators have raised the prospect of increased risk of renal fibrotic disease in response to gadolinium scanning. As such, the next investigation would be duplex scanning, with progression to traditional angiography if required, with (of course) adequate fluid loading to reduce the risk of contrast nephropathy.

[Q: 1836] OnExamination 2012 - Cardiology

A 16-year-old male presents with acute severe asthma.

On examination his peripheral pulse volume fell during inspiration.

Which one of the following is the most likely explanation for this clinical sign?

- 1- A falling heart rate on inspiration
- 2- Myocardial depression due to hypoxia
- 3- Peripheral vasodilatation
- 4- Reduced left atrial filling pressure on inspiration
- 5- The cardiac effect of high dose beta agonist bronchodilator drugs

Answer & Comments

Answer: 4- Reduced left atrial filling pressure on inspiration

This patient is demonstrating pulsus paradoxus.

The right heart responds directly to changes in intrathoracic pressure, while the filling of the left heart depends on the pulmonary vascular volume.

At high respiratory rates, with severe air flow limitation (for example, acute asthma) there is an increased and sudden negative intrathoracic pressure on inspiration and this will enhance the normal fall in blood pressure.

[Q: 1837] OnExamination 2012 - Cardiology

A 72-year-old man with a history of oesophageal carcinoma is recovering on the surgical ward after oesophagostomy.

You are asked to see him because he has developed worsening central chest pain, looks pale and sweaty and has dropped his blood pressure to 100/55 mmHg with a pulse of 92. He has bibasal crackles on auscultation of the chest.

Investigations show

Haemoglobin 10.8 g/dl(13.5-18)

White cell count $9.0 \times 10^9/L$ (4-10)

Platelets $180 \times 10^9/L$ (150-400)

Sodium 139 mmol/l (134-143)

Potassium 4.4 mmol/l (3.5-5)

Creatinine 145 $\mu\text{mol/l}$ (60-120)

ECG Anterior ST elevation consistent with acute MI

Which of the following is the most appropriate management?

- 1- Angioplasty
- 2- Aspirin, clopidogrel and low molecular weight heparin
- 3- Aspirin, clopidogrel, low molecular weight heparin and abciximab
- 4- CABG

5- Thrombolysis

Answer & Comments

Answer: 1- Angioplasty

Thrombolysis is contraindicated in this gentleman due to his recent surgery, and anti-platelet therapy with or without IIb3a inhibitor will provide limited advantage in a man with a STEMI, while simultaneously increasing his risk of significant bleeding so soon after surgery.

As such, there is only one logical management plan for him: to consider angioplasty.

Evidence suggests angioplasty is superior to thrombolysis in the general population, and as such, this man should be managed aggressively and transferred to the catheter lab as soon as is practicable.

[Q: 1838] OnExamination 2012 - Cardiology

Which of the following mechanisms best explains the action of OMACOR (omega-3-acid ethyl esters)?

- 1- Activation of PPAR-alpha
- 2- Bile acid sequestration
- 3- Decreases hepatic cholesterol synthesis
- 4- Increases peroxisomal beta-oxidation of fatty acids
- 5- Inhibits cholesterol absorption

Answer & Comments

Answer: 4- Increases peroxisomal beta-oxidation of fatty acids

OMACOR reduces triglycerides by different, independent effects in the liver.

The synthesis of triglycerides is inhibited through reduced production of triglycerides in the liver, as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are poor

substrates for the enzymes responsible for triglyceride synthesis.

EPA and DHA also inhibit esterification of other fatty acids.

OMACOR increases peroxisomal beta-oxidation of fatty acids in the liver.

[Q: 1839] OnExamination 2012 - Cardiology

A 60-year-old man has left ventricular failure and clinically he is classified as NYHA Class III.

He takes furosemide, aspirin and ramipril.

The addition of which one of the following betablockers would be expected further to improve his prognosis?

- 1- Acebutolol
- 2- Bisoprolol
- 3- Esmolol
- 4- Propranolol
- 5- Sotalol

Answer & Comments

Answer: 2- Bisoprolol

Bisoprolol is a highly selective beta1-adrenoceptor antagonist.

Administration of bisoprolol to patients with chronic heart failure is associated with increases in left ventricular function and reductions in heart rate; increases in heart rate variability are also seen.

Two major randomised, double-blind, placebo-controlled, multicentre trials have examined the clinical efficacy of bisoprolol in combination with ACE inhibitors and diuretics in patients with stable chronic heart failure (New York Heart Association class III or IV).

Reference:

Drugs. 2002;62(18):2677-96

[Q: 1840] OnExamination 2012 - Cardiology

A 48-year-old man presents with acute coronary syndrome.

On examination he has palmar crease xanthoma.

Which of the following is the most likely diagnosis of his lipid abnormalities?

- 1- Familial combined hyperlipidaemia
- 2- Familial hypercholesterolaemia
- 3- Familial hypertriglyceridaemia
- 4- Lipoprotein lipase deficiency
- 5- Remnant hyperlipidaemia

Answer & Comments

Answer: 5- Remnant hyperlipidaemia

Remnant hyperlipidaemia (type III hyperlipidaemia) is associated with:

Hypercholesterolaemia, typically 8-12 mmol/l

Hypertriglyceridaemia, typically 5-20 mmol/l

Normal ApoB concentration

Palmar xanthomata - orange discoloration of skin creases

Tuberoeruptive xanthomata - elbows and knees

Early onset of cardiovascular disease

Early onset of peripheral vascular disease.

Remnant hyperlipidaemia is due to abnormal function of the ApoE receptor, which is normally required for clearance of chylomicron remnants and IDL from the circulation.

The receptor defect causes levels of chylomicron remnants and IDL to be higher than normal in the blood stream. The receptor defect is an autosomal recessive mutation or polymorphism.

The genotype of the homozygous condition is apo E-2/E-2 and occurs with a frequency of 1:100.

[Q: 1841] OnExamination 2012 - Cardiology

A 62-year-old male who is being treated for stable angina presents with muscle aches and pains. He has been taking simvastatin 40 mg daily, atenolol 50 mg daily together with aspirin 75 mg daily for approximately two years.

Recently he was admitted for an episode of acute coronary syndrome and a number of other therapies were added. You suspect a statin-related myopathy and a CPK concentration is 820 iu/l (50-200).

Which of the following is most likely to be responsible for the precipitation of his statin-related myopathy?

- 1- Bisoprolol
- 2- Clopidogrel
- 3- Diltiazem
- 4- Omega-3 fatty acids
- 5- Spironolactone

Answer & Comments

Answer: 3- Diltiazem

Statin-associated myopathy occurs in up to 5% of those treated with statins and may be exacerbated by the co-prescription of other drugs such as calcium channel blockers, macrolide antibiotics, fibrates, amiodarone and grapefruit juice.

Whilst patients may tolerate a statin extremely well, a myopathy or rhabdomyolysis can quite easily be precipitated by the addition of these agents.

[Q: 1842] OnExamination 2012 - Cardiology

A 72-year-old man with type 2 diabetes mellitus presented following the sudden onset of palpitations.

An ECG revealed rapid atrial fibrillation. He was commenced on amiodarone but the atrial fibrillation persisted.

Which of the following has been shown to be of greatest benefit in reducing his future risk of vascular events?

- 1- Anticoagulation
- 2- Aspirin
- 3- Continuation of amiodarone
- 4- DC cardioversion
- 5- Digoxin

Answer & Comments

Answer: 1- Anticoagulation

Both sustained and paroxysmal atrial fibrillation (AF) are associated with a relatively high incidence of thromboembolism and stroke.

Clinical trials have demonstrated that warfarin reduces the risk of stroke in patients with AF. This benefit outweighs the risk of bleeding.

[Q: 1843] OnExamination 2012 - Cardiology

A 43-year-old man presents to the Emergency department with a three hour history of chest pain. He has a history of 'angina' diagnosed by his GP. He is awaiting objective assessment to confirm this. His GP started aspirin and gave him a GTN spray with instructions how to use it.

The pain came on after walking up a hill but has not gone away. He took three puffs of GTN but this had no significant effect. He looks sweaty and unwell. You review his 12 lead ECG but it looks normal to you. You think

this patient has an acute coronary syndrome (ACS) and decide to admit for assessment.

Which of the features listed below is a good indicator of presence of acute coronary syndrome?

- 1- Associated feeling of impending doom
- 2- Associated nausea and sweating
- 3- Good response to GTN
- 4- Pain in chest lasting at least one hour
- 5- Pain which varies with patient's position

Answer & Comments

Answer: 2- Associated nausea and sweating

Diagnosis of ACS is based on clinical history and/or presence of ischaemic ECG changes with or without troponin elevation. Each of these should not be relied upon in isolation but interpreted in the context of the others.

In March 2010 NICE produced clinical guidance on the assessment of chest pain (CG 95). It listed clinical factors which are good indicators of ACS. These included typical pain lasting at least 15 minutes and associated nausea and sweating.

The guidance specifically mentions that response to GTN should not be used as GTN has a strong placebo.

[Q: 1844] OnExamination 2012 - Cardiology

A 75-year-old lady has been referred to you in the cardiology clinic with a four month history of breathlessness on exertion. She has a 20 year history of hypertension and type II diabetes, controlled with insulin.

On questioning she has noted gradually progressive breathlessness with mild ankle oedema. She has noted worsening symptoms at night.

On examination her venous pressure is not elevated but there are slight bibasal crackles.

Her heart sounds are normal and there is mild oedema. You arrange further tests and follow up.

Regarding the heart failure, which of these clinical signs has the greatest sensitivity in detecting heart failure?

- 1- Oedema
- 2- Pulmonary crackles
- 3- Raised jugular venous pressure
- 4- Tachycardia
- 5- Third heart sound

Answer & Comments

Answer: 5- Third heart sound

The clinical syndrome of heart failure is not a diagnosis; a cause for cardiac dysfunction must be found.

Symptoms and signs of heart failure tend to lack sensitivity and specificity; heart failure will be misdiagnosed about half of the time when based solely on clinical features.

The sensitivity of a third heart sound has been estimated at approximately 30%. The sensitivities of answers A, B, C and D are approximately 10%, 13%, 10%, 7% respectively.

Therefore the correct answer is E.

[Q: 1845] OnExamination 2012 - Cardiology

An 82-year-old former soldier with no prior medical history of note was admitted following appendicitis treated with laparoscopic appendicectomy a week previously.

At laparotomy the appendix was inflamed though not perforated. The operative notes describe an uncomplicated procedure with minimal blood loss. There were no immediate post-operative issues of note, with stable blood count and biochemistry.

The bowels opened at day three, and the patient was back to his usual diet and level of independent mobility by day six. He has lived alone since being widowed over twenty years ago, is fully mobile and self-caring, and feels able to return home without any home help.

He is referred to the medical team prior to discharge to address a consistently high systolic blood pressure, ranging around 160 - 170 mmHg, over repeated readings during the course of the admission, with no diurnal variation. Similar readings are obtained from all four limbs, in lying and standing positions.

A review of his history indicates that the patient takes over the counter analgesia as required, but has never required medical care. He is a former smoker, but gave up many years ago. He has a good diet, and walks his dog two miles a day.

On clinical examination the patient is euvolaemic with an undisplaced apex, normal heart sounds and no bruits. Undilated fundoscopy is normal. Urine dipstick demonstrated a trace of ketones but nil else. The cardiac axis is normal on ECG. Biochemistry, including renal function, fasting glucose and lipid profile, is normal. BMI is calculated at 22 kg/m².

What is the best strategy to manage this patient's hypertension?

- 1- 24 hour urine collection to look for proteinuria
- 2- Aggressively modify lifestyle factors
- 3- Ambulatory blood pressure monitor
- 4- Avoid antihypertensives in view of the risk of falls
- 5- Offer antihypertensive therapy

Answer & Comments

Answer: 5- Offer antihypertensive therapy

The hypertension in the very elderly trial [HYVET] clarified uncertainty surrounding the control of blood pressure in elderly patients,

and whether its benefits outweighed the risks of side effects in an aged population.

It compared diuretics, plus or minus ACE inhibitors, against placebo in patients above 80 years of age. This yielded not only a decrease in cardiovascular events, but also appreciably improved all cause mortality. The trial set a target blood pressure of 150 / 80, and it is unclear at this stage whether aiming for a lower target will reap further benefit.

It is also uncertain which classes of drugs are best, and in which order. Thiazides, ACE-inhibitors and calcium channel blockers have been advocated in a stepwise fashion.

In this case, the trace of ketones on urine dipstick is of no consequence in a patient with established diet and bowel habit who is euvolaemic and has recently had abdominal surgery. In the absence of a positive urine dipstick there is no need to pursue the possibility of proteinuria.

This patient has little in the way of lifestyle factors to modify, being a non-smoker with frequent exercise, good diet and normal BMI.

Regular blood pressure monitoring has in effect been carried out during the week of admission, with a consistently elevated blood pressure and an ambulatory blood pressure monitor would add little. Note that in this population it is important to measure blood pressure in all four limbs, and in lying / standing positions, in view of the risks of diffuse arterial disease and orthostatic hypotension respectively.

Denying this patient antihypertensives in fear of falls is inappropriate in the context of his mobility and independence.

Comprehensive overview of evidence to date.

[Q: 1846] OnExamination 2012 - Cardiology

A 58-year-old man with a history of schizophrenia on thioridazine is found to have episodes of torsades de pointes ventricular tachycardia (VT).

His blood pressure is 110/70 mmHg.

Which of the following is the most appropriate management?

- 1- IV betablocker
- 2- IV lidocaine
- 3- IV magnesium
- 4- Overdrive pacing
- 5- Synchronised DC cardioversion

Answer & Comments

Answer: 3- IV magnesium

Thioridazine, an antipsychotic, and many other drugs can prolong the QT interval and increase the risk of torsade de pointes VT.

Self-limiting bursts of torsade may be seen on an ECG and prompt urgent treatment.

[Q: 1847] OnExamination 2012 - Cardiology

A 38-year-old teacher attends the hypertension clinic, having been referred via her general practitioner following a sequence of elevated systolic blood pressure readings.

Though she is worried about the long term consequences of hypertension she has never trusted the medical profession, is worried about the possible side effects of medication, and wishes to control her blood pressure through alternative therapies.

Which of the following interventions is part of currently advocated measures to reduce blood pressure?

- 1- Acupuncture
- 2- Ginseng

- 3- High fibre diet
- 4- Meditation
- 5- Sodium supplements

Answer & Comments

Answer: 4- Meditation

The Dietary Approaches to Stop Hypertension [DASH] diet demonstrated a convincing and dynamic link between dietary intake and systemic blood pressure, with rapid improvement in blood pressure on a fruit and vegetable-based diet with low dairy and fat consumption. However this is yet to translate into novel lifestyle modifications.

Though a vast body of work is available on complementary therapies for hypertension, of the above only relaxation therapies have been conclusively shown to reduce blood pressure as part of a preventative effort to improve a patient's risk profile.

Sodium supplements are the opposite of what is recommended, with dietary salt restriction being a key and effective part of advice.

Calcium, magnesium and potassium supplements have some tenuous supporting data against the background of other contradictory studies, and are not recommended in national guidelines.

Ginseng has anecdotally been associated with hypertension. Sadly long term compliance with drastic changes in a lifelong diet is poor.

Other conventional and well-known lifestyle measures against hypertension include increased exercise, weight loss, moderation of alcohol intake and smoking cessation. These aims should be reiterated when consulting any patient with new or indeed longstanding hypertension.

Reference:

NICE Clinical Guideline 34: Hypertension. National Institute for Health and Clinical Excellence, London (2006).

Savica et al. Annu Rev Nutr 2010; 30: 365 - 401: review of dietary methods of controlling hypertension

[Q: 1848] OnExamination 2012 - Cardiology

A 60-year-old woman with ischaemic heart disease is seen for review.

She reports that she has developed symmetrical muscle aches and pains and you attribute this to a myalgia associated with simvastatin. Her creatinine kinase is within the normal range.

However, her dyslipidaemia management is still sub-optimal and you wish to add in a further agent.

Total cholesterol 5.5 mmol/l (<5.2)

LDL cholesterol 3.8 mmol/l (<3.36)

HDL cholesterol 1.3 mmol/l (>1.55)

Triglycerides 1.4 mmol/l (0.45-1.69)

You plan to continue the statin treatment.

Which of the following agents would be the most appropriate additional therapy for this patient?

- 1- Cholestyramine
- 2- Ezetimibe
- 3- Gemfibrozil
- 4- Nicotinic acid
- 5- Omega-3 fatty acids

Answer & Comments

Answer: 2- Ezetimibe

This patient presents with a probable statin-induced myalgia which often improves with time. Sometimes stopping therapy briefly or re-introducing a different statin may resolve the myalgia.

Statin-induced myositis is relatively uncommon occurring in approximately 0.1-0.2%. The risk of myositis and the potentially

fatal rhabdomyolysis is, in prone subjects, increased with gemfibrozil in combination with a statin and as such should be avoided.

Additional agents could include omega-3 fatty acids and ezetimibe.

Nicotinic acid is less used due to problems with flushing though can be useful particularly in hypertriglyceridaemia.

Cholestyramine can also be used.

In this case it is the low density lipoprotein (LDL) cholesterol that needs to be targeted and ezetimibe would be the most appropriate choice.

[Q: 1849] OnExamination 2012 - Cardiology

Cyanosis is a typical feature of which of the following conditions?

- 1- Atrial septal defect (ASD)
- 2- Mitral atresia.
- 3- Patent ductus arteriosus.(PDA)
- 4- Total anomalous pulmonary venous drainage.
- 5- Ventricular septal defect.(VSD)

Answer & Comments

Answer: 4- Total anomalous pulmonary venous drainage.

Total anomalous pulmonary venous connection (TAPVC) is associated with cyanosis in the newborn.

TAPVC consists of an abnormality of blood flow in which all four pulmonary veins drain into systemic veins or the right atrium with or without pulmonary venous obstruction.

Systemic and pulmonary venous blood mix in the right atrium.

PDA, ASD and VSD are left to right shunts.

Tricuspid atresia is typically associated with cyanosis rather than mitral.

[Q: 1850] OnExamination 2012 - Cardiology

In a normal heart, the oxygen saturation of a sample of blood taken from a catheter in the pulmonary capillary wedge position should be equal to a sample from which of the following?

- 1- Coronary sinus
- 2- Femoral artery
- 3- Pulmonary artery
- 4- Right atrium
- 5- Right ventricle

Answer & Comments

Answer: 2- Femoral artery

Pulmonary capillary wedge normal values reflect pressures and saturations of the left side of the heart and therefore reflect the arterial system.

Consequently the saturations of blood taken from the wedged source reflect blood in the pulmonary vein (that is, oxygenated blood) and hence high saturations similar to that seen in the femoral artery.

[Q: 1851] OnExamination 2012 - Cardiology

Whilst attending the cardiology clinic, the staff nurse measures the blood pressure of a 61-year-old man, and finds that it is 183/100 mmHg sitting and 190/105 mmHg standing.

He has a heart rate of 81/minute, with an irregularly irregular rhythm.

On auscultation of the heart, there are no murmurs, but he has bibasilar crackles on chest examination.

Which of the following pathological findings is most likely to be present?

- 1- Cor pulmonale
- 2- Left atrial myxoma
- 3- Left ventricular hypertrophy (LVH)
- 4- Mitral regurgitation
- 5- Occlusive coronary atherosclerosis

Answer & Comments

Answer: 3- Left ventricular hypertrophy (LVH)

This gentleman is likely to have a hypertensive cardiomyopathy with a left ventricle hypertrophy.

The LVH is secondary to increased afterload, as a result of chronic hypertension. The atrial fibrillation suggested by an irregularly irregular pulse, is an indicator of diastolic dysfunction and poor ventricular filling.

This in turn indicates the pulmonary congestion, as evidenced by the bibasal crackles.

There is no murmur or plop to suggest atrial myxoma.

[Q: 1852] OnExamination 2012 - Cardiology

A 75-year-old lady presents with sudden breathlessness and palpitations.

On examination, she was observed to have an irregular heart beat with rate of 140 bpm, BP 85/40 mmHg and normal heart sounds. On auscultation of the chest, fine basal crepitations are heard.

An ECG confirms atrial fibrillation (AF) and an old inferior myocardial infarction. She is anticoagulated with heparin and given diuretics. Her heart rate remains rapid.

What is the most appropriate management of the lady's AF?

- 1- DCCV
- 2- IV amiodarone
- 3- IV beta-blocker

4- IV digoxin

5- Oral quinidine therapy

Answer & Comments

Answer: 1- DCCV

The key to this question is that the patient has clinical signs of pulmonary oedema with fast AF and hypotension.

In this age group AF is poorly tolerated and often leads to pulmonary oedema even in the presence of a relatively normal left ventricle (LV).

NICE have published guidance on the treatment of AF.

The primary aim here should be rate control which is best achieved with direct current cardioversion (DCCV) in this situation.

Digoxin even when used intravenously is suggested to have too slow an onset of action to merit its use.

B-blockers can also be used but due to the fact that they are negatively inotropic may complicate the acute pulmonary oedema.

Emergency DCCV is required as there is haemodynamic compromise (low BP).

Reference:

M Bilal Iqbal, Anil K Taneja, Gregory Y H Lip, and Marcus Flather. *Recent developments in atrial fibrillation*. BMJ, Jan 2005;330:238-243

[Q: 1853] OnExamination 2012 - Cardiology

Which of the following is true regarding the action of clopidogrel?

- 1- It inhibits cyclo-oxygenase
- 2- It is a glycoprotein IIb/IIIa inhibitor
- 3- It is a hydroxymethyl co-enzyme A inhibitor
- 4- It is a selective factor Xa inhibitor
- 5- It is an ADP receptor antagonist

Answer & Comments

Answer: 5- It is an ADP receptor antagonist

Clopidogrel prevents platelet aggregation through antagonism of the adenosine diphosphate (ADP) receptor.

It has been shown to reduce mortality from stroke and ischaemic heart disease (IHD) in primary prevention studies.

[Q: 1854] OnExamination 2012 - Cardiology

A 34-year-old patient with longstanding primary hypertension presents in her first pregnancy. ECG, urine dipstick and fundoscopy are normal. Her current blood pressure is 140 / 95.

What is the maximal acceptable blood pressure?

- 1- 120 / 70
- 2- 130 / 70
- 3- 140 / 80
- 4- 150 / 90
- 5- 150 / 100

Answer & Comments

Answer: 5- 150 / 100

The target blood pressure in patients with pre-existing hypertension is under 150 / 100, or 140 / 90 in the presence of end organ failure.

In patients with longstanding hypertension aggressive blood pressure control may compromise placental function, so diastolic blood pressure should be preserved above 80 mmHg.

Any increase in blood pressure above baseline should prompt a search for new pre-eclampsia, testing full blood count, renal and liver function, urinary protein / creatinine ratio, and observing blood pressure closely.

Reference:

NICE Clinical Guideline 107: Hypertension in pregnancy. National Institute for Health and Clinical Excellence, London (2010).

[Q: 1855] OnExamination 2012 - Cardiology

A 43-year-old woman presents to the emergency department with diarrhoea and vomiting over the past 48 hours. She has a history of hypertension for which she takes indapamide 1.5 mg daily, but no other past medical history of note.

On examination she looks unwell and has a BP of 122/71 mmHg and a pulse of 79. Her abdomen is soft but there is tenderness consistent with her gastroenteritis.

Investigations show

Haemoglobin 14.8 g/dl(11.5-16)

White cell count $9.8 \times 10^9/L$ (4-10)

Platelets $174 \times 10^9/L$ (150-400)

Sodium 140 mmol/l (134-143)

Potassium 2.9 mmol/l (3.5-5)

Creatinine 139 $\mu\text{mol/l}$ (60-120)

Which of the following is most likely to be found on her ECG?

- 1- Atrial fibrillation
- 2- J waves
- 3- Peaked T waves
- 4- Shortening of the QT interval
- 5- ST depression

Answer & Comments

Answer: 5- ST depression

When potassium falls below 3 mmol/l, the ECG often demonstrates:

- Flattening of the T waves
- ST depression
- QT prolongation
- Prominent U waves.

Patients are at increased risk of ventricular ectopics, torsades de pointes and ventricular tachycardia.

Other constitutional symptoms associated with hypokalaemia of less than 3.0 mmol/l include:

- Tiredness
- General weakness
- Muscle pain
- Constipation.

[Q: 1856] OnExamination 2012 - Cardiology

A 40-year-old male attends for a consultation after discovering that his brother has been diagnosed with a familial hypertrophic obstructive cardiomyopathy (HOCM).

Which screening method should he be offered?

- 1- Coronary angiogram
- 2- Exercise ECG
- 3- Genetic testing
- 4- Transoesophageal echocardiogram
- 5- Transthoracic echocardiogram

Answer & Comments

Answer: 5- Transthoracic echocardiogram

Current guidelines suggest that a resting ECG and TTE (transthoracic ECHO) are the most effective screening strategy for relatives of patients with HOCM.

Genetic testing is not recommended as a first line screening tool, given varying rates of penetrance.

[Q: 1857] OnExamination 2012 - Cardiology

On physical examination of a 42-year-old man you find a 'jerky' pulse.

Which of the following conditions is most associated with a 'jerky' pulse?

- 1- Aortic stenosis
- 2- Cardiac tamponade
- 3- Hypertrophic obstructive cardiomyopathy
- 4- 'Mixed' aortic valve disease
- 5- Severe left ventricular failure

Answer & Comments

Answer: 3- Hypertrophic obstructive cardiomyopathy

Hypertrophic obstructive cardiomyopathy (HOCM) is typically associated with a jerky pulse although it may present with entirely normal clinical findings.

[Q: 1858] OnExamination 2012 - Cardiology

A 67-year-old man with insulin-dependent diabetes with a broad complex pulseless tachyarrhythmia (with a protected airway) has just been defibrillated for the third time without return of cardiac output -CPR is immediately resumed and adrenaline administered.

Which of the following is the next step in the management of the arrest?

- 1- Adrenaline 1 mg
- 2- Amiodarone 300 mg
- 3- DC shock
- 4- Lidocaine 100 mg
- 5- Removal of oxygen and then DC shock

Answer & Comments

Answer: 2- Amiodarone 300 mg

The next step is amiodarone 300 mg intravenously (i.e. given after the third shock), if amiodarone is not available lidocaine is a suitable alternative.

[Q: 1859] OnExamination 2012 - Cardiology

A 59-year-old male has been discharged from hospital following an uncomplicated admission with myocardial infarction (MI) and treated with stenting. His therapy at discharge included aspirin 75 mg daily, clopidogrel 75mg daily, ramipril 10 mg daily, atenolol 50mg daily and simvastatin 40 mg daily.

On subsequent review, one month after discharge, he is well and unaware of any chest pain. His blood pressure is 134/78 mmHg and he has a resting heart rate of 66 bpm. There are no abnormalities on auscultation of the heart or chest.

Investigations reveal:

Cholesterol 4.6 mmol/l (<5.2)

Triglyceride 0.8 mmol/l (0.45-1.69)

Glucose 5.6 mmol/l (3.0-6.0)

U&E Normal

Which of the following therapies added to his current treatment regime would be expected to reduce mortality still further?

- 1- Amlodipine
- 2- Ezetimibe
- 3- Furosemide
- 4- Omega-3 fatty acids
- 5- Vitamin E

Answer & Comments

Answer: 4- Omega-3 fatty acids

Of the agents suggested, omega-3 fatty acids (in essence fish oils) have been demonstrated in the GISSI-prevenzione study to reduce mortality in this particular group of patients with coronary artery disease on standard treatment by a further approximate 20% for all cause mortality and 40% reduction in sudden deaths versus controls.

Vitamin E therapy was associated with no significant differences.

It appears that omega-3 fish oils may have a benefit beside improving lipid profile with increases in high density lipoprotein (HDL) and reductions in triglyceride, as it has been suggested that they may confer some anti-arrhythmic effect.

Short-acting calcium antagonists early after MI possibly increase mortality, and certainly have no beneficial effect.

Similarly, furosemide has no data to indicate improved outcome.

Ezetimibe, which inhibits cholesterol reabsorption has no data to indicate a survival advantage.

[Q: 1860] OnExamination 2012 - Cardiology

A 29-year-old male is admitted with a one hour history of severe central chest pain associated with vomiting.

It transpires that he used cocaine three hours ago. His blood pressure is 142/74 mmHg and he has a pulse of 110 beats per minute regular. His ECG reveals 3 mm ST segment elevation in leads V2-5.

Which of the following is the most appropriate treatment for this patient?

- 1- Abciximab
- 2- Angiography +/- PTCA
- 3- Isoket (isosorbide dinitrate) infusion
- 4- Low molecular weight heparin
- 5- Tissue plasminogen activator (rtPA)

Answer & Comments

Answer: 3- Isoket (isosorbide dinitrate) infusion

Cocaine is a drug of widespread abuse and remains one of the commonest causes of acute myocardial infarction (MI) in men below 35 years of age.

The aetiology of cocaine-induced MI is thought to be related to coronary artery spasm as many patients do not have overt coronary artery disease. This vasoconstriction is thought to be more accentuated in those with pre-existing coronary artery disease or those who smoke. It is probably caused by stimulation of the β -adrenergic receptors in smooth muscle cells. In addition, cocaine increases endothelin-1 (a vasoconstrictor) and decreases nitric oxide (vasodilator).

Consequently guidelines suggest the use of nitrates in the first instance coupled with calcium antagonists. Intravenous benzodiazepines are also effective in resolving chest pain and improving cardiac performance. If there is no improvement in the clinical condition, then angiography should be considered. Fibrinolytics are generally avoided.

Reference:

ACC Guidelines 2007, J Am Coll Cardiol 2007;50:1-157

Management of Cocaine-Associated Chest Pain and Myocardial Infarction. A Scientific Statement From the American Heart Association Acute Cardiac Care Committee of the Council on Clinical Cardiology. McCord J et al. Circulation 2008;117:1897-1907.

[Q: 1861] OnExamination 2012 - Cardiology

A 74-year-old man presented with intermittent chest pain at rest.

Which one of the following would most strongly suggest that the pain was due to myocardial ischaemia?

- 1- Associated dyspnoea
- 2- Coexistent claudication
- 3- Past history of cigarette smoking
- 4- Radiation of pain to the jaw
- 5- Relief of pain by sublingual nitrate

Answer & Comments

Answer: 4- Radiation of pain to the jaw

Nitrates may relieve the pain of oesophageal spasm, as well as that of myocardial ischaemia.

Associated dyspnoea may be due to anxiety.

Coexistent claudication suggests the presence of peripheral vascular disease.

A past history of cigarette smoking is a risk factor for the development of cardiovascular disease.

However, the most specific feature of the given options which suggests that the pain is myocardial ischaemia, is the radiation to the jaw, which is relatively specific for pain of myocardial ischaemia.

[Q: 1862] OnExamination 2012 - Cardiology

A 40-year-old female with mitral stenosis consults for advice regarding operative procedures.

In which of the following circumstances would antibiotic prophylaxis of infective endocarditis be required?

- 1- Caesarian section
- 2- Cardiac catheterisation
- 3- Dental scaling
- 4- No indications for prophylaxis
- 5- Termination of pregnancy

Answer & Comments

Answer: 4- No indications for prophylaxis

Antibiotic prophylaxis against endocarditis is now not recommended in common cardiac valve abnormalities.

Prophylaxis is only recommended in those patients who are at highest risk of adverse

outcomes on the development of endocarditis. These patient groups include:

Prosthetic cardiac valve or prosthetic material used for cardiac valve repair

Previous endocarditis

Unrepaired cyanotic congenital heart disease including palliative shunts and conduits

Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first six months after the procedure

Repaired congenital heart disease with residual defects (persisting leaks or abnormal flow) at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialisation)

Cardiac transplantation recipients who develop cardiac valve abnormalities.

[Q: 1863] OnExamination 2012 - Cardiology

A 30-year-old man presents with a history of transient loss of consciousness and palpitations. His ECG shows ventricular tachycardia (VT).

Which of the following treatments should be avoided?

- 1- Adenosine
- 2- Amiodarone
- 3- DC cardioversion
- 4- Flecainide
- 5- Verapamil

Answer & Comments

Answer: 5- Verapamil

If there were 'killer' questions (questions that if a candidate got wrong they would certainly fail the exam) in the MRCP examination then this would be one of them.

Verapamil should be avoided in cases of VT because it can cause a catastrophic fall in blood pressure.

Adenosine is useful diagnostically when the diagnosis of regular wide complex tachycardia is in doubt.

Amiodarone is a useful antiarrhythmic agent though its use acutely is limited by its irritant nature on veins.

DC cardioversion is probably the treatment of choice in this case.

Flecainide is a good antiarrhythmic and would be indicated in patients without left ventricular (LV) failure (it is associated with an increased risk of death in such cases).

Flecainide is widely used for atrial fibrillation.

[Q: 1864] OnExamination 2012 - Cardiology

A 73-year-old woman with atrial fibrillation due to ischaemic heart disease is well controlled with digoxin and amiodarone. She presents with a two month history of weight loss and palpitations.

Examination reveals an irregular pulse of 110 bpm.

Investigations show:

Serum TSH < 0.05 mU/L (0.2-5.5)

Serum total T4 140 nmol/L (58-174)

Which of the following would be the most useful investigation in establishing the diagnosis of thyrotoxicosis?

- 1- Antithyroglobulin antibody titre.
- 2- Antithyroid peroxidase antibody titre.
- 3- Serum free T4 concentration.
- 4- Serum reverse T3 concentration.

- 5- Serum total T3 concentration.

Answer & Comments

Answer: 3- Serum free T4 concentration.

Amiodarone may cause both hypo- and hyperthyroidism.

It also interferes in the peripheral conversion of T4 to T3.

This patient appears thyrotoxic and of the measures given free T4 is most appropriate.

[Q: 1865] OnExamination 2012 - Cardiology

A 64-year-old man is admitted with a right femoral neck fracture following a fall.

Also seen in the radiograph of the pelvis are several prominent calcified vessels.

What is the most appropriate next step in management of this finding?

- 1- Anticoagulate with heparin
- 2- Ignore it
- 3- Order a pulmonary ventilation-perfusion scan
- 4- Request a serum troponin test
- 5- Start the patient on a nitrate infusion

Answer & Comments

Answer: 2- Ignore it

This finding is typical for Monckeberg's calcific medial sclerosis, a benign condition involving muscular arteries of older persons.

[Q: 1866] OnExamination 2012 - Cardiology

A 52-year-old male presents with a three week history of fevers, deteriorating breathlessness and fatigue. Two years ago he underwent prosthetic valve replacement for a calcified bicuspid aortic valve.

On examination he has a temperature of 37.7°C and four nail-fold infarcts. Vegetations are demonstrated through transoesophageal echocardiography.

Which of the following is the most likely causative organism?

- 1- Candida spp.
- 2- Enterococcus
- 3- Staphylococcus aureus
- 4- Staphylococcus epidermidis
- 5- Streptococcus viridans

Answer & Comments

Answer: 5- Streptococcus viridans

Generally there are two identifiable modes of prosthetic valve endocarditis.

The first occurs in the first year after surgery affecting 0.7-3% of cases and is often due to Staphylococci.

Late endocarditis observed after two years post-surgery is found in 0.5-1% of cases and is typically due to Streptococci, typically group A haemolytic Streptococci, otherwise known as Strep. viridans.

[Q: 1867] OnExamination 2012 - Cardiology

A 58-year-old male has a 6 year history of hypertension for which he is receiving Candesartan, Amlodipine, Bendroflumethiazide and Aliskiren.

Which of the following best describes the mechanism of action of Aliskiren?

- 1- Aldosterone synthase inhibitor
- 2- Aldosterone receptor blocker
- 3- Bradykinin inhibitor
- 4- Direct renin inhibitor
- 5- Second generation angiotensin receptor antagonist

Answer & Comments

Answer: 4- Direct renin inhibitor

Aliskiren is a direct renin inhibitor and represents the first new class of drug available in over a decade for the treatment of hypertension. Renin has long been recognized as a possible site for blockade of the renin-angiotensin-aldosterone system (RAS) because it prevents conversion of angiotensinogen to angiotensin I and is a rate-limiting step in the RAS cascade.

Aliskiren binds to the active site of the renin molecule, blocking angiotensinogen cleavage, thus, preventing the formation of angiotensin I. Clinical studies have demonstrated at least equivalent blood pressure lowering efficacy compared with existing drugs with a favourable side effect profile.

[Q: 1868] OnExamination 2012 - Cardiology

What is troponin?

- 1- A component of thick filaments
- 2- A component of thin filaments
- 3- A myosin heavy chain
- 4- A myosin light chain
- 5- A substance produced by pulmonary vascular endothelium

Answer & Comments

Answer: 2- A component of thin filaments

Troponin is a component of thin filaments (along with actin and tropomyosin), and is the protein to which calcium binds to accomplish this regulation.

Troponin has three subunits, TnC, TnI, and TnT.

When calcium is bound to specific sites on TnC, the structure of the thin filament changes in such a manner that myosin (a molecular motor organised in muscle thick filaments)

attaches to thin filaments and produces force and/or movement.

In the absence of calcium, tropomyosin interferes with this action of myosin, and therefore muscles remain relaxed.

[Q: 1869] OnExamination 2012 - Cardiology

A 28-year-old man with a known history of congenital heart disease presents with a pansystolic murmur, large V waves in the JVP and pulsatile hepatomegaly.

Which of the following types of congenital heart disease is most likely to be associated with this presentation?

- 1- Atrial septal defect
- 2- Coarctation of the aorta
- 3- Ebstein's anomaly
- 4- Patent ductus arteriosus
- 5- Ventricular septal defect

Answer & Comments

Answer: 3- Ebstein's anomaly

The clinical features suggest tricuspid regurgitation. The correct answer is therefore Ebstein's anomaly.

The hemodynamic consequences of Ebstein anomaly result from displaced and malformed tricuspid leaflets and atrialization of the right ventricle. The leaflet anomaly leads to tricuspid regurgitation. The severity of regurgitation depends on the extent of leaflet displacement, ranging from mild regurgitation with minimally displaced tricuspid leaflets to severe regurgitation with extreme displacement.

[Q: 1870] OnExamination 2012 - Cardiology

A 74-year-old patient with a history of ischaemic heart disease presents with

shortness of breath. He is finding difficulty mobilising any further than around his home.

An ECHO demonstrates an ejection fraction of approximately 20%. He is on maximal drug therapy for heart failure, and is not thought to have an infective chest exacerbation. An ECG demonstrates sinus rhythm with a rate of 75/min and widened QRS complexes.

What is the most appropriate treatment option?

- 1- Addition of perhexiline therapy
- 2- Palliation as an in-patient with PRN morphine
- 3- Referral for biventricular pacing
- 4- Referral for cardiac transplant
- 5- Referral for implantable defibrillator

Answer & Comments

Answer: 3- Referral for biventricular pacing

This patient by definition has NYHA III heart failure (HF).

The CARE-HF study of heart failure patients has shown a 37% reduction in the primary end point of death and cardiovascular hospitalisation and a reduction of 36% in all-cause mortality compared with control. Control patients were treated with maximal medical therapy only, and follow-up was a mean of 29 months.

Examination of the COMPANION study demonstrates a 40% reduction in the risk of death or hospitalisation from HF, and a 36% reduction in death from any cause, after implantation of biventricular pacing wires with a defibrillator.

It may be that in the very near future we will be implanting biventricular pacing devices, with defibrillator actions, in those patients in the subject groups included in these studies.

The indications for implantation devices in these studies were low ejection fraction,

dyssynchrony on the ECG (widened QRS), and NYHA III/IV.

Perhexiline therapy may become standard therapy in this patient subgroup in the future, but as yet there is no mortality or morbidity evidence to support its widespread use.

[Q: 1871] OnExamination 2012 - Cardiology

A post-marketing surveillance study of a new heart failure therapy to the market was carried out on 10,000 subjects who had completed clinical trials.

Which one of the following most accurately reflects the information generated from such a study?

- 1- Adverse events profile
- 2- Comparative therapeutic efficacy
- 3- Cost benefit analysis
- 4- Cost effectiveness
- 5- Drug potency

Answer & Comments

Answer: 1- Adverse events profile

Post-marketing surveillance (PMS)/observational studies (phase IV studies) generally are designed to assess the potential side effects of new drugs but under everyday conditions and with a minimum of intervention.

In contrast to the randomised controlled trials, PMS typically includes patients from more extreme age groups and patients with comorbidity or other risk factors.

In order to cover a wide spectrum of patients and to observe rare events with sufficiently high probability, PMS enrolls a large number of patients, typically several thousands.

Comparative efficacy has already been undertaken in phase III studies (RCTs) but can also be undertaken as part of specific RCT

studies later in the drugs development and potency usually in phase I and II studies.

[Q: 1872] OnExamination 2012 - Cardiology

A 34-year-old man presented for an insurance medical. He was symptom free, but clinical examination suggested a small ventricular septal defect (VSD).

Which one of the following findings was most likely to have been present?

- 1- A short systolic murmur at the left sternal edge
- 2- A systolic murmur maximal at the apex
- 3- A systolic murmur with thrill at the left sternal edge (LSE)
- 4- An early diastolic murmur
- 5- Fixed splitting of the second heart sound

Answer & Comments

Answer: 3- A systolic murmur with thrill at the left sternal edge (LSE)

Typically, a small VSD generates a pansystolic murmur at the LSE accompanied by a thrill. The murmur may be heard at the apex but is usually loudest at the LSE.

Very small defects may generate an early/late systolic murmur.

Fixed splitting of the heart sounds usually accompanies atrial septal defects.

[Q: 1873] OnExamination 2012 - Cardiology

You are asked to see a patient in the intensive care unit who is short of breath and tachycardic to rule out a cardiac cause of her symptoms.

A right heart catheter reveals that the mixed venous O₂ saturation is 70%; the pulmonary capillary wedge O₂ saturation is 97%. The

haemoglobin is normal and the patient is afebrile.

Which of the following is the most appropriate statement that could be applied to her features?

- 1- Her cardiac output is decreased
- 2- Her cardiac output is normal
- 3- Her heart is normal
- 4- She has high-output failure
- 5- She is in shock due to a non-cardiac cause

Answer & Comments

Answer: 2- Her cardiac output is normal

The right heart and wedge catheters show normal saturations, the latter suggesting that she has good pulmonary oxygenation and so these features would argue against any failure.

Decreased or high output failure would certainly argue against shock of any sort; therefore, one cannot go as far as to say that she has a normal heart, so the best response (by a process of elimination) is that she has a normal output.

[Q: 1874] OnExamination 2012 - Cardiology

A 14-year-old boy presents with hypertension.

Which of the following statements concerning hypertension in the young is true?

- 1- Abnormalities are frequently seen on DMSA scan
- 2- Aortic coarctation is the commonest secondary cause
- 3- Headache is the usual presenting feature
- 4- It is defined as systolic blood pressure above the 99th centile for age
- 5- Sodium nitroprusside is useful for the long term treatment of severe cases

Answer & Comments

Answer: 1- Abnormalities are frequently seen on DMSA scan

Sodium nitroprusside is useful only in the short term, as cyanide levels accumulate with time.

Hypertension is usually diagnosed incidentally, and is defined as systolic blood pressure greater than the 95th centile for age.

Secondary causes are usually due to renal abnormalities, with reflux-associated scarring being the commonest renal disease. This will cause abnormalities on dimercaptosuccinic acid (DMSA) scan.

Coarctation of the aorta is the commonest non-renal cause, with pheochromocytoma/neuroblastoma, congenital adrenal hyperplasia, Cushing's syndrome and steroid therapy being rarer causes.

[Q: 1875] OnExamination 2012 - Cardiology

A 28-year-old man who is known to have hypertrophic cardiomyopathy (HCM) has an out of hospital cardiac arrest and is successfully resuscitated.

What is the most appropriate mode of treatment?

- 1- Alcohol septal ablation
- 2- Amiodarone
- 3- Beta-blocker
- 4- Implantable defibrillator
- 5- Myomectomy

Answer & Comments

Answer: 4- Implantable defibrillator

Patients with HCM are at increased risk of sudden cardiac death (SCD) due to ventricular fibrillation/tachycardia (VF/VT). Implantable

cardio-defibrillators (ICD) are superior to amiodarone or β -blockers for preventing this.

Reducing outflow tract obstruction with myomectomy or alcohol septal ablation does not reduce the risk of SCD.

Other indications for ICD implantation include:

Cardiac arrest due to VF/VT.

Sustained VT causing haemodynamic compromise.

Chronic heart failure, left ventricular ejection fraction (LVEF) less than 40% and associated syncopal episodes due to non-sustained VT post-myocardial infarction, non-sustained VT with LVEF less than 40%.

Arrhythmogenic right ventricular cardiomyopathy causing cardiac arrest.

Congenital long QT with family history of sudden cardiac death at young age.

[Q: 1876] OnExamination 2012 - Cardiology

A 56-year-old man presents to the Emergency department with an inferior myocardial infarction. He has a history of smoking and hypertension and is a poor attendee at the GP surgery.

On initial admission he is hypotensive and bradycardic, with clear inferior ST elevation. He is taken to the catheter lab and stented. You are asked to see him a few hours later as he is persistently hypotensive with poor urine output. He has remained pain free since his stenting.

On examination his BP is 90/50 mmHg, his pulse is 69, he has an elevated JVP, but his chest is clear.

Investigations show

Haemoglobin 14.0 g/dl (13.5-17.7)

White cell count $6.6 \times 10^9/L$ (4-11)

Platelets $188 \times 10^9/L$ (150-400)

Serum Sodium 138 mmol/l (135-146)

Serum Potassium 5.3 mmol/l (3.5-5)

Creatinine 131 $\mu\text{mol/l}$ (79-118)

Which of the following is the most appropriate next step?

1- IV Dobutamine

2- IV Fluid loading

3- IV Nitrate

4- Rescue angioplasty

5- Thrombolysis

Answer & Comments

Answer: 2- IV Fluid loading
